GLEANINGS IN BEE CULTURE.

DEVOTED TO BEES, HONEY & HOME INTERESTS.

Vol. XIX. **JAN. 1, 1891.** **No. 1.**

TERMS: $1.00 PER ANNUM, IN ADVANCE; 2 Copies for $1.90; 3 for $2.75; 5 for $4.00; 10 or more, 75 cts. each. Single number, 5 cts. Additions to clubs may be made at club rates. Above are all to be sent to ONE POSTOFFICE.

Established in 1873.
PUBLISHED SEMI-MONTHLY BY
A. I. ROOT, MEDINA, OHIO.

Clubs to different postoffices, NOT LESS than 90 cts. each. Sent postpaid, in the U. S. and Canadas. To all other countries of the Universal Postal Union, 18 cts. per year extra. To all countries NOT of the U. P. U., 42 cts. per year extra

STRAY STRAWS.

EDITED BY DR. C. C. MILLER.

What a winter!

Bees flying a little Dec. 15.

What splendid kindling old wood separators make!

SUB-VENTILATORS are still in high favor with Mrs. Harrison.

I don't know how Rev. W. F. Clarke can make such good poetry about what he doesn't know.

American Bee Journal for 1891 is to have 1664 pages. How does friend Newman expect us to bind it?

Winter days have come,
Bees no longer hum;
They hibernate some.

If 3 lbs. of honey make 1 lb. of wax, wouldn't it be better to raise wax at 20 cts. a pound than to raise 5-cent honey?

A writer in the *British Bee Journal*, who has "both straw skeps and movable-frame hives, likes the latter better."

CLOSED-END FRAMES, according to W. Camm, in *The Guide*, do not have the combs fastened as well to the end-bars as open-end frames.

Heddon says that one of the reasons (and he puts the reason in capitals) that he sold his honey so quickly, was, that he *kept the prices down.*

I have four colonies of bees outdoors—the first in perhaps 20 years. "Why haven't I tried it before?" Well, I don't know whether it was more prejudice or laziness.

Rev. W. F. Clarke and Bro. Newman are having quite a controversy as to whether Canadians are Americans. When they agree on it, we'll know for sure just how it is.

HILL AND HUTCHINSON are down on the corners of the Dovetailed hive. Is there any law to prevent the two H.'s from making the same hive with an improved corner, like a common store-box?

COVER PICTURE.—That of the *Review*. It's ahead—neat, appropriate, beautiful. The only chance for any one else to beat Hutchinson is to copy his cover, and then sew it with colored instead of white thread.

"LOCK-JOINTED HIVE-CORNERS" is the heading to an item in the *Review* about the "so-called Dovetailed hive." Say, W. Z., why didn't you, years ago, lift up your voice against the "so-called dovetailed" section?

Hasty thinks 3 lbs. or less of honey will make a pound of wax; Simmins, less than 6½ lbs.; tradition, 20. Don't we stick to that 20 from mere habit? I do. Has there been a single experiment of late years to confirm it?

Whether your cellar needs ventilation for the bees or not, if your wife and children are worth keeping you will do well to see that the air in your cellar is sweet and pure at all times. Pure air won't *hurt* the bees, at any rate.

JAPAN CLOVER is spoken of in the *American Bee Journal* as a kind that flourishes well, at least in the South, doing well even on the poorest, stoniest land. It is highly praised as a plant for grazing, but nothing is said of its value for honey.

UPWARD VENTILATION, according to the *British Bee Journal*, is not desirable. It says, "Personally we prefer to keep the top close—just as the bees will make it if left to themselves—and to ventilate from the bottom. We have come round to this view after trial of both methods."

BLACK BEES the *British Bee Journal* decidedly prefers to the Italian, for profit and for all-round superiority. It says, "After several years' trial, our most experienced and successful bee-keepers have generally discarded Italian (or Ligurian) bees in favor of the old black or brown variety." How's that?

A British writer recommends having extracting-combs 2 inches from center to center, to prevent the queen going up into them. I think there is something in it. With 2-inch sections I never had much trouble with the queen going up, even when I used neither separator nor honey-board.

Joshua Bull, in the *American Bee Journal*, thinks, "when we have frequent storms, with heavy discharges of electricity in the form of lightning and thunder, the honey-flow is apt to be light; but when there is less thunder and lightning, there is more honey in the flowers." Well, what can you do about it?

Isn't contraction beginning to expand a little? Dr. Tinker says, in the *Canadian Bee Journal*, that contraction "is now admitted by all the ablest producers of comb honey in this country to be necessary to the best results." But he has decided, that "it does not pay to carry the contraction too far." He thinks "the equivalent of 6 L. brood-combs is the best."

And now it's Hasty I am mad at. I like Hasty, he's always so fresh and bright. But in the *Review* he hints that the venerable falsehood, that it takes twenty pounds of honey to make one pound of comb, is kept alive by the bee-journals in the interest of the foundation business. Hasty, did you ever know any of them to suppress any evidence that 3 lbs. of honey make a pound of wax? That hint wasn't nice. It was hasty—almost with the top knocked off the h.

Foul brood in Canada is not likely to be kept hidden. Any person, whether bee-keeper or not, who knows of a case and does not report it to the proper authority, "shall, on summary conviction before a justice of the peace, be liable to a fine of $5 and costs." That's right. It's different here. At a bee-convention a public official announced the existence of a large number of cases of foul brood; and when I pressed for the names, he said he would not tell, *because the parties did not want it known!*

Artificial increase is practiced by E. France to prevent swarming. He runs outapiaries for extracted honey, with no one to watch for swarms. He visits them every week to ten days. When they get so strong that there is danger of swarming in a good honey-flow, he takes from each such colony about two combs of honey and brood—mostly brood—taking bees with it but no queen, and puts in place empty combs or foundation starters. Thus from 3 to 6 colonies he gets enough to fill an empty hive, which in a few days makes a strong working colony. Next visit he cuts out queen-cells.

AMOUNT OF STORES FOR WINTER, ETC.

G. M. DOOLITTLE GIVES US SOME FACTS GLEANED FROM YEARS OF EXPERIENCE.

The following from a correspondent is just at hand: "How much food does each colony of bees require, in order to winter successfully? I find Mr. Hasty telling in the *Review* of starting doubled-up colonies with as little as five or six pounds, while some of the 'doctors' say that fifty pounds in a hive is better than any thing less. Which am I to believe? and what am I to understand by this great difference of opinion?"

Well, these things are often very confusing to a beginner, and I do not wonder at it; but, as a rule, the writer of an article in any of our periodicals can not well go into all of the minutiæ connected with his or her subject, because it would make too long an article for one number or issue of such periodical; and continued "stories" do not seem to be just the thing for a bee-paper. That none need be thus confused, my advice to *all beginners* would be, that they purchase one or more of our valuable books on bee culture, and in these they will find the most if not all they want to know about spoken of at length, and the reasons for the writers' opinion given, so that they can form an opinion at once whether the writers' views are correct or not. With this prelude I will proceed to answer as best I can.

While I do not think that 50 lbs. of honey should be required to winter a colony of bees, under any condition, yet the amount required depends very largely on the location, whether the bees are wintered in the cellar or on the summer stand, and upon what is meant by "winter." It will be plain to all, that more stores would be required to winter a colony where winter held its sway from the middle of October to the middle of April, as it does in some of our most extreme northern localities where bees are kept, than would be required in some of the more southern localities where winter does not last over two months.

If I understood Mr. Hasty aright in the *Review*, his idea of so little honey was to give only enough honey during the winter months *proper* to supply the "fuel" required to keep the colonies warm, and not to supply them food for brood-rearing in the spring. He argued that this scanty supply of food tends to make the bees retrench, and so they would use this supply *only* for fuel, and thus early brood-rearing, which is considered by many to be of no advantage, would be done away with, thus wintering our bees at little cost, and at the same time place them in a condition which is most conducive to their prosperity. But Bro. H. did not calculate that the supply he gave them in the fall was to last them till honey was gotten from the fields in the spring, for he plainly told us that he had a supply reserved, to fall back on when the supply given in the fall gave out.

The only thing I see against this "short-store" plan, as given by Bro. H., is, that in our locality the bees might run out of supplies at a time when it would be impossible, on account of protracted cold, to supply their wants, thus increasing the probability of loss to those who are a little inclined to be careless with their pets. Years, ago, when I first began to keep bees, I thought that each colony wintered on their summer stand should have at least 30 lbs. of honey to carry them from the first of October to the first of May; but after repeated trials I am fully satisfied that 20 lbs. is just as good as 30, and I find that not one colony in 25 will consume 15 lbs. during this time. The only reason for giving the 20 lbs. instead of 15, lies in the fact that the bees will retrench when their stores are getting low, just as Bro. Hasty tells us; and if this retrenching comes when the bees ought to be rearing brood, then we are losing largely by not having honey enough in the hive to keep brood-rearing prospering as it should.

I claim that all colonies wintered on the summer stand should have at least ten pounds of honey in their hives the middle of April, in this locality, to give them the confidence they need to start out aright with for the season; for with this amount of stores they will not feel the need of retrenching, but will push brood-rearing on rapidly. If they can be wintered on 5 lbs. up to this time, so much the better; but, if at this time they do not have plenty of honey it should be supplied to them in some shape. For cellar wintering I allow 5 lbs. less honey than for outdoor wintering, finding that, as a rule, 1½ lbs. of stores per month is the average amount consumed by the bees while in the cellar. Now, where we feed our bees, no matter how done, I find that it can be done to better advantage in the spring than in the fall, for the bees will go to brood-rearing with renewed vigor where fed; and for this reason I would say, give the bees only enough to safely carry them through to May, then supply their wants by feeding the amount you would otherwise have given them in the fall. The amount which I think right in this locality, I have given above.

INTRODUCING QUEENS TO QUEENLESS COLONIES IN THE SPRING.

Another correspondent wishes to know whether he can successfully introduce a queen to a colony which has been wintered without one. He seems to fear that such a colony would establish laying workers during the winter season, and thus make the introduction of a queen a perilous undertaking. I do not know that I ever placed a colony in winter quarters, knowing that they were queenless, but I have several times had queenless colonies in the spring which I believed had been queenless nearly all winter, and had no especial trouble in getting them to accept a queen at that time. I can not say for certain, but I do not think that the bees would establish laying workers while in winter quarters; at least, I never knew of a laying worker, in this locality, earlier than the first of June. Can any of the readers of GLEANINGS give us any light on this subject? It would have much to do with our trying to winter over queenless colonies. G. M. DOOLITTLE.

Borodino, N. Y., Dec. 17, 1890.

[I heartily agree with you, friend D., in every thing you say, only you do not consider at all the strength of the colony. When we used to try to winter nuclei, say with a quart of bees or more, if we succeeded in getting them to pull through, they consumed, of course, but a small quantity of food; and if they dwindled down so there would be but a pint of bees in the spring to build up with, it took only a very small amount of stores for them to build up. I think I have wintered nuclei with not to exceed 5 lbs. of stores; and this took them clear up to the bloom of the soft maples; and at the same time I have had powerful colonies, say with four times as many bees as the nucleus mentioned, that would consume 20 lbs. It is true, however, that less stores will be needed in proportion for a powerful colony than for a weak one, especially during winter time. As the powerful colony will, however, start a tremendous sight of brood before the nucleus has commenced brood-rearing at all, they will need stores correspondingly. And the amount of brood reared, and the time when brood-rearing commences with a certain colony, has very much to do with the amount of stores needed. We therefore finally arrived at the conclusion of many of our veterans, that each *full* colony should have from 20 to 25 lbs. of stores, in order to be *absolutely* safe, providing they were not looked over in the spring especially to see how their stores were holding out. But with this large amount of stores, many will often have sealed stores left when work commences in the boxes; and this is an argument in favor of ten-frame hives instead of eight-frame. The two extra frames *may* contain surplus stores the year round, as a sort of reserve force to fall back on in case of drouth or famine, or excessive brood-rearing.

I can not remember that I have ever had any trouble in introducing a queen to a colony found queenless in the spring; and we, in such cases, turn them right loose, the bees often receiving them with a roar of applause. I do not know that I ever saw them "swing their hats," but they make a loud buzz with their wings, and the news passes from one to another very much as shouts of applause go through a crowd of human beings.]

WHITE SNAKEROOT (EUPATORIUM AGERATOIDES).

DOES IT CAUSE THE DISEASE CALLED "MILK-SICKNESS"?

Friend Root: — Prof. Cook pronounces the plant sent by Mr. Hastings (see p. 793) "the common boneset, or thoroughwort, sometimes called white snakeroot." Although I am not a botanist, I can tell the professor, that, although they may be ranked with the same family of plants, there is quite a difference. Boneset is a much larger, stronger-growing plant than snakeroot; and the leaves that spring from the body of the main stalk entirely encircle it, so that they connect with one another, and the stalk has the appearance of growing *through* the blades, while the snakeroot is entirely destitute of the band that encircles the other. The seed-blossoms on the top of the plants resemble each other very much. There is a mistake somewhere. Mr. Hastings may have sent thoroughwort instead of snakeroot; and if he did, the professor made a mistake.

In regard to the "trembles" in cattle, and milk-sickness among those who use the milk of cows that eat it, I have had a pretty sad experience, but not as bad as some of my neighbors. When I came to Ohio in 1844 I heard that there was a section of country on the road from Medina to Seville where the settlers had been afflicted with a strange malady that the doctors could give no name to, and several deaths had occurred the year before; but the general opinion was that it was somehow caused by the water. I took up a new farm on the road one mile west of the main road to Seville, but my neighbors' woods and mine joined, and then everybody's cattle ran in the woods; but it was so much trouble to hunt mine up that I cut a "slash row" around *my* lot. Well, we would hear of sickness *east* of us; but with the exception of a little ague, one year, we enjoyed good health for ten years; but the year 1855 was a dry one in the latter part of the summer, and the water failed on my farm. I let my cattle into the woods for water, and, of course, among the snakeroot. Soon a sucking colt died; then my oldest boy was taken ill, and then there was a general bad feeling, among us all; but I did not send for a doctor, for I dreaded *them* more than any disease. I was then 46 years old, and my wife 41; but neither of us had ever taken a dose of medicine of any kind *from* a *doctor*. A week passed; wife sick; yearling steer died with trembles; shut the cattle out of the woods, and cut corn for them. Stephen, my boy, had been seven days without any thing passing his bowels—could eat nothing, drank but little, and generally threw that up.

I would say here that we had abandoned the use of milk and any of its products. Stephen said that he wanted some *ice*. I took the old jumper from the stable, mounted her, and took a pail and went to the village and got a good big "hunk," and cut it up so he could get the pieces into his mouth, and he "crunched" it up and swallowed it before it had a chance to melt. After a short spell he commenced to vomit, and threw up not only the water but the contents of a very foul stomach; and from that hour he began to mend. Suffice it to say, that, of the seven of us in the family, we were all sick but the six-year-old boy (the youngest), and he had generally eaten much more *maple sugar* than he had *butter*. I was called a stubborn, stingy, ignorant, wicked man because I would not have a doctor; but we all lived, while several of my neighbors died, with the doctors all around them.

I have written these lines so that any one sick with that complaint may have the benefit of my experience. I consider Dr. Tyrrell's remarks on page 779 of GLEANINGS to be like "apples of gold in pictures of silver" to any one who will heed them. JESSE HARRINGTON.

Medina, Ohio, Nov. 25.

[Friend H., do not be too severe on Prof. Cook. We find, by the botanies, that the thoroughwort, or boneset family, includes a very large number of varieties; and although the white snakeroot looks very different indeed from what we in our locality call boneset, or thoroughwort, it is still one of the species included under that name. Years ago I sent a sample of the plant to Samuel Wagner, and my sample was taken from the very woods you allude to in your article. He at once pronounced it white snakeroot, or *Eupatorium ageratoides*. The piece of woods has always been of great interest to me, from the fact that, as cattle and all other stock have been for so many years excluded, it is becoming a dense thicket of trees, plants, and shrubs—quite a contrast, in fact, to most of the timber land throughout Ohio. From the fact that stock has been for so many years excluded from the woodlands where this plant seems to thrive, I am inclined to think that it, or some other one, has something to do with milk-sickness. Years ago I thought it richly deserved a place in our greenhouses on account of the beauty of its snow-white mass of bloom, and I remember well when I first found it in a greenhouse. Now almost every florist has one or more varieties of *Eupatorium* with their downy tassel-shaped flowers of snowy whiteness. Recently a tinted variety is found in some collections. The little flowers and the mass of bloom have become developed by greenhouse culture to much greater size and magnificence than they are in their native woods. Bees get an amber-colored honey, of a peculiar rich flavor, some seasons, from this plant. Perhaps I should mention that thoroughwort has a strong, sweetish perfume—sometimes so great as to be almost sickening, while the snakeroot-blossom has no trace of this distinctive perfume at all. It has, however, a delicate sweet perfume of its own, but not at all like the thoroughwort.]

BEE-KEEPING FOR WOMEN.

A FEW THINGS THAT HELP MATERIALLY TO LIGHTEN THEIR LABORS.

Under favoring circumstances I can put in a long day's work with bees—often, in the busy season, getting up at four o'clock; and, when at work in the out-apiaries, not reaching home until nine o'clock in the evening. But I feel pretty sure that, under some circumstances, it would be very little work I could do with bees. Take, for instance, the matter of shade. If I were obliged to work in some apiaries where they arrange their hives in an open plat with only shade-boards or vines, and the operator is obliged to take the full rays of the hot sun, I am afraid it would be a very short time that I could stand it. In our apiaries the hives are so arranged that they are in the shade at least part of the day; and in planning our work for the day we always, so far as is possible, see to it that those hives which will be in the sun in the afternoon are worked in the forenoon, and *vice versa*. Sometimes we don't plan just right; then Dr. Miller takes the sun. I suppose men are better able to stand the heat than women; but I can hardly see why it is necessary for either to do so. What objection is there to trees, providing the shade is not too dense? They help the bees to mark their location; and, oh they are such a comfort to the bee-keeper if he keeps them trimmed properly!

Last spring we were very busy, and neglected to trim the branches in the Wilson apiary. Whenever I heard an ejaculatory "oh!" I knew what the matter was, and would look up to see Dr. Miller's hat jammed over his eyes, and both hands full. One day, after having been tried in that way a number of times, he stopped short with a remark something like this: "I'm going to trim these branches, even if I don't do another thing to-day." He did trim them and it didn't take so very long either, and they had been a big nuisance for some time. You see, I rather had the advantage of him, for I could pin my hat on firmly.

It's the little things that help to make our work hard or easy. I should hardly like to work with bees if I were obliged to do all the heavy lifting. But Dr. Miller kindly favors me in that direction—so much so that I remonstrate sometimes. He generally assures me that it is pure selfishness on his part, as he wants to get as much help from me as possible, and knows I can accomplish a good deal more if I don't overdo. Every lady bee-keeper will find a pair of rubber boots and a good gossamer (one with sleeves if possible) a great help—in fact, almost a necessity. Showers sometimes come up when work is pressing, and you are obliged to keep on. I have in mind twice this last summer, when we worked in a pouring rain because we had a lot of queen-cells that must be attended to at once.

Again, you can not wait in the morning for the grass to dry off, and you will find your rubber boots a great convenience. Now, don't say, as I did, that they are entirely too heavy and warm, and that you know you never can wear them. Well, I *had* to, as Dr. Miller got me a pair and insisted on my trying them. I like them. So will you. EMMA WILSON.

Marengo, Ill., Dec. 15.

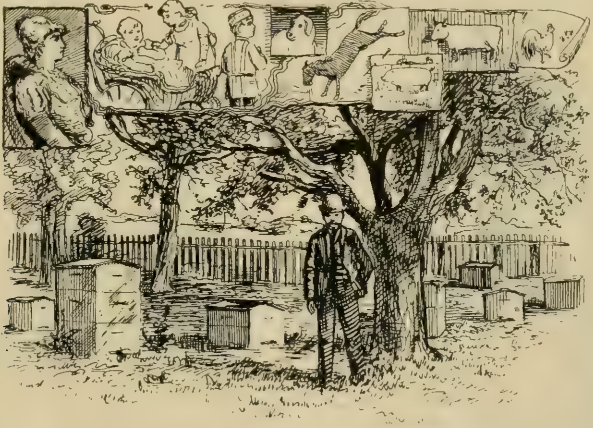
[Good shade in an apiary is indeed a luxury, even to a *man*, and to the poor bees, also, when not too dense. It is very hard to be obliged to work in the hot sun, over hives all day, without at least a little shade a part of the day. Shade-boards are inconvenient, as you say. About the best thing, I think, is small trees, or trees that do not have a very dense foliage. Large apple-trees are rather bad; small ones are just right. Grapevines are hardly the thing, in my estimation. They require such constant trimming, and that during the busiest part of the time in the apiary, that either one or the other of two things happens—they are either neglected, or they stick out in the way unless attended to so that they take valuable time away from the bees. A small boy can do it, it is true; but somehow or other it does not get done at our home apiary. I never had my hat crammed down over my eyes as you say Dr. Miller has had, but I have had an ugly shoot from a vine that had been cut off, punch me in the face; and I have felt more than once as if I wanted to tear the whole thing up, root and branch. This matter of shade is one of the important questions, and I hope our correspondents will discuss it.

You will remember, three or four years ago I recommended light rubber boots to work with in the apiary, and I am glad you have spoken of their convenience to *women*. Very often, during the morning, the grass will be soaking wet; and if your yards are like ours, somehow or other the grass will become long, so as to make common rubbers an insufficient protection. After I had recommended light rubber boots we had quite a number of orders for them. I would say to our good friends, that we sell a good many things; but boots are among the articles that we do not wish to handle just yet. The kind I mentioned can be obtained at any of the stores.] E. R.

RAMBLER IN PROVIDENCE.

HOFFMAN FRAMES AND BEE-SPACES; NO BURR-COMBS.

We performed the duties required of us on the apiarian exhibit; and not seeing much anger in the faces of the exhibitors, we concluded it was safe for us to stop a few days in Rhode Island. We learned that Mr. Cushman was doing a good work at the Experiment Station, and it was through the unremitting labors of Mr. Miller and Prof. Cushman that the premium list was extended and the exhibit enlarged; and if the people of Rhode Island remain in ignorance upon bee-keeping and the methods of honey-production, it will not be the fault of the bee-keepers. The exhibit from the Experiment Station was intended to be instructive; and at almost any time of day we found Mr. Cushman patiently answering questions and correcting erroneous ideas.



ARTHUR C. MILLER'S HOME AND HOBBIES.

Several of the exhibitors acknowledged themselves to be merely amateurs, and had taken it up for its diverting effect. Mr. Thos. M. Pierce, of Wickford, lost his health by too close application to business, and had gained a very good degree of vigor among the bees and flowers. Mr. Pierce and family adopted the novel plan of eating as much honey as they could, and giving away the rest. One youth, with a taste for sweetness, got away with over 40 lbs. It proved a sure way of using up the surplus; but when he changed the order of things and put the usual price on his goods there was a sort of reaction. The recipients of past favors were no better customers than outside parties.

At the close of the day's labors we were whisked off by rail to Barrington, and the residence of Arthur C. Miller, several miles out of Providence. Mr. Miller's time at bee-management is mostly in the morning and evening. The rest of his time is devoted to banking business in the city. It is a delightful run out of Providence to Barrington. We follow down Narragansett Bay; and the many beautiful cottages along the shore and upon the islands reminded us strongly of our own lovely Lake George. Here, however, instead of fishing for pickerel, larger game was sought after. Only swordfish, sharks, and kindred fish, will satisfy the ambitious fisherman of Rhode Island.

Stakes protruding from the water all along down the bay were pointed out as the boundary lines between the oyster-beds, from which the Rhode Islander derives a large revenue. When we left the rails, and rolled peacefully along in a chaise behind the pet horse of the family, we remarked about the hardness and pearly whiteness of the roads, and were informed that they were made so by the liberal application of oyster-shells; and when informed that there were miles and miles of such roads, and thousands of loads of shells were used for other purposes, we began to realize the magnitude of the oyster-business. As you may suppose, these beautiful roads are a veritable paradise for the bicyclist, and we found Mr. Miller owned such a pet, and was expert in its use.

Mr. Miller has a commodious and pleasant home, with a wife and three little ones to welcome him after the cares and fatigues of the day. In the rear of the house is a large yard and kennel for the pet blood-hound; and beyond, the poultry-house with the pet rooster. A cow has been added recently to give pure lacteal food for the little ones, and to give Mr. Miller necessary recreation in the early morn. A cow is always an object-lesson of patience, and there is not a family in the land that does not venerate the family cow. The manipulator of the lacteal glands is also taught the virtues of patience, especially when flies abound.

A few years ago Mr. Miller had a fine apiary; but sickness necessitated a change of climate, and he spent the winter in California, leaving his bees in the hands of inexperience. A severe loss followed, and the apiary has to be built up again under the master's hand. This will soon be accomplished, if future seasons equal the present. With three full colonies and two nuclei in the spring, an increase to ten has been made, with abundant winter and spring stores, and 385 lbs. of surplus, both comb and extracted; and, under careful management, the honey is of a gilt-edged order, and commands a good price. Rhode Island bee-keepers, as far as we observed, sell all their honey in the home market, and we saw no piles of special shipping-crates in their apiaries.

The Hoffman frame is used in this apiary, and the spacing of frames, and from frame to honey-board or crate, is large enough to give the bees easy access, and no larger—we should say a scant $\frac{5}{16}$; and when the crates are removed, not a brace-comb is visible. Italians and Carniolans are in the apiary; but Mr. Miller favors the Carniolans, and often laments the loss of a valuable strain of them when he was absent. He has not replaced them, but hopes to find ere long a Carniolan with all the desirable qualities.

As your readers will remember, Mr. Miller is the inventor of the best foundation-fastener yet devised. We here saw its practical working for the first time, and foundation can be securely stuck to the sections with rapidity, leaving no thick rib next to the section. The apiary is comfortably located under the spreading branches of apple-trees of the Roger Williams variety. We did the town of Barrington, and found many elegant residences. City people live out here, and spend their surplus dollars in adorning their grounds, and they are good to look upon; but the greatest comfort a Rhode Islander can attain to is a clam-bake; and every cottage and club-house along shore is provided with the necessary appliances to produce the effect. It was a little late in the season for bakes, but we heard so much about them that we feel quite well posted on clams.

This is a Clam

A CLAM BEE-KEEPER OF THE "BRIMSTONE" DAYS.

The clam is a very conservative animal, and is seldom influenced by outside considerations. The clam is considered selfish, as he shuts his door in the face of all intruders, and even his aunts, his uncles, and his cousins, are served the same way. The clam will not open his doors to the interviewer, and all he wants is to be let alone, to pursue the even tenor of his way just as his grand-dad did. If Mrs. Clam wants to put on an airy back kitchen, or a front bay window to their old shell, Mr. Clam gets in a rage, and closes his front doors closer than ever. Scientists do not agree as to whether the clam is a biped or a quadruped. Usually just after Mrs. Clam has given him an extra good dinner, he has a faint resemblance to a biped: at all other times he has all the qualities of a quadruped. "Don't be a clam," is the advice of the RAMBLER.

[I have a great respect for a man who has hobbies, particularly if they are of a kind that makes the man love home and family more. A man who loves pets, and is kind to them, will necessarily be kind to his family. What you say regarding the Hoffman frames, and their freedom from burr-combs, is literally true. I saw the same state of affairs in more than one apiary in the East; and I confidently expect it in our own yards at an early date.] E. R.

THE DOVETAILED CHAFF HIVE.

OBJECTIONS TO THE OUTSIDE WINTER PROTECTING-CASE.

There are decided objections to such an outside case as is suggested by Ernest on page 698. If made the size mentioned, there will be too little space for packing. There will be some difficulty, I think, in adjusting the cushions so that one can always feel positive that there are no unoccupied spaces left for the free circulation of air.

The adjusting of cushions and case will require a skilled workman, and will consume more time than would be required to tuck up the same number of colonies in regular chaff hives.

There are too many pieces that will need storing for a part of the year, causing too much carrying back and forth between the stands and the honey-house. A little extra cost of a hive, when used for a term of years, is a small thing; but a little extra work, often repeated, is of some importance; and the longer the hive is used, the smaller is the importance of the cost and the greater the importance of the time consumed to manipulate it.

If it were possible, there should be no part of the hive requiring storage at any time, excepting the supers. These we want stored during the winter, so that they may be filled with sections for the following season.

It is true, that such a temporary winter case can be used by those who already have their bees in the Dovetailed hive. This is some advantage, but not as great as at first appears; for if we adopt an eight-frame chaff hive, the Dovetailed hives thus relieved from service will not be lost, as, with such a hive, we shall need a number of just such bodies for summer use, with which to form nuclei, to hive swarms, and to form second stories for extracting, if such should be needed. If there were a greater number than would be required for these purposes, they could easily be ripped in two, and thus be converted into supers.

Another advantage of such a case is, that it could be used early in the honey season to protect the supers from cold. Later, as the hot weather comes on, they might be converted into quite efficient shade-boards by removing the cushions. For this purpose they would require to be a little larger than suggested—large enough, in fact, to slip over the Dovetailed cover.

The advantage of cheapness, which Ernest urges, I am not willing to admit. His statement of the cost reminds me of a woman of my acquaintance, who regularly, every Monday morning, says to her little boy, "Now, Johnny, mother washes to-day, so you must bring a pail of water before going to play." Johnny willingly brings the stated amount, when his mother says, "Now another." After that has been brought, "Now another;" then, "Now another:" then, "Now another;" then, "Now just one more." It is fortunate that the mother always stops at the sixth pail; for about that time there comes a look on Johnny's face that leads me to think there might be a small rebellion were she to call for the seventh. To keep us good-natured, tell us right at the start how much this 35-cent chaff hive will cost, when you have figured in all that will be required to make it a complete one-story chaff hive. Let us see. There will be one dovetailed body; one bottom-board; one piece of duck to cover the frames; one cushion to cover the duck, and one long cushion, over five feet, to surround the dovetailed body.

If, after thoroughly discussing the matter, the committee find sufficient advantages to overbalance the disadvantages, why not compromise the matter a little and construct it so that it can be used either in the way mentioned, or converted into the permanent outside shell of a one-story chaff hive? Make it of ⅜-inch lumber, dovetailed at the corners, as proposed, but somewhat larger, so that it will take thicker cushions. Instead of a complete cover, put on a rim-piece somewhat similar to those used on the other chaff hives. When the rim-pieces are in place, the shoulder should be just like the upper edge of a dovetailed body—flat—⅛ inch wide on the side, and ½ inch on the ends, and should stand sufficiently above the rest of the rim to admit of the use of the regular dovetailed cover. To use as a removable winter protection, adjust the case and side cushions, just as you would the one proposed by Ernest. Now you have access to the top, and can tuck in the top cushion so that you are positive every thing is snug. Then just slide on the regular hive-cover, and make it useful winter as well as summer. You may not wish to examine your bees at all from the time they are prepared for winter until the next season; but it is worth something to know that you can do so if you wish, without tearing your hive all apart.

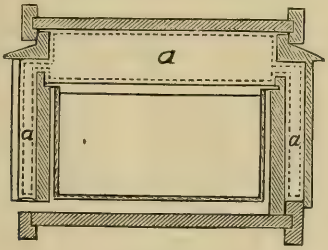


FIG. 1.

To make a chaff hive with permanent packing, there will be needed an inside shell made of ⅜-inch lumber, and dovetailed at the corners, and bottom-boards similar to those used in the other chaff hives, if it is thought advisable to have packing under the brood-nest.

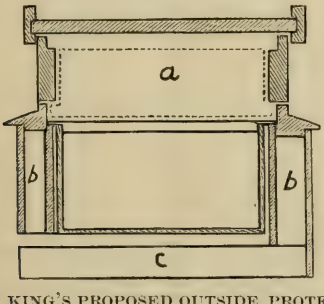

FIG. 2. KING'S PROPOSED OUTSIDE PROTECTING-CASE FOR THE DOVETAILED HIVE.

Since it has been decided to use such a large entrance, winter as well as summer, what is the use of extra protection at the bottom? Why not use only one bottom-board, leaving simply a dead-air space beneath?

Figure 1 shows a longitudinal section of a Dovetailed hive, with the protection and cushions, *a*, *a*, *a*, in place.

Figure 2 shows the case made into a chaff hive, in which *a* is the chaff cushion; *b*, *b*, chaff packing, and *c* a dead-air space.

Marysville, O., Dec. 15. W. A. KING.

[Criticisms are always in order, friend King, and I am free to acknowledge that you make some good points. Let us consider some of them *seriatim*. Allowing me to be the judge (for I have tried them), the adjusting of the outside cases, as you suppose, will not take nearly as much time as the same number of colonies in regular chaff hives, and there is going to be, I think, nothing to lug back and forth. These outside cases will be needed in summer for comb honey, as a protection from the hot sun. Elwood, with his thousand colonies, uses just such an outside case for shade, and he did not consider it a superfluous affair, if I remember correctly. Of course, the cushions would have to be put away; but then, we have to do that with our regular chaff hives. We can not afford to have great lumbering cushions on the hives during the entire summer; and in the production of honey they must necessarily be removed to make room for the supers. You say, a little extra cost of the hive, when used for a number of years, is a small thing. Very true; but the smaller this extra cost, the smaller this thing becomes. A regular chaff hive is not adapted for moving, but a single-walled hive is. Toward winter the outside cases can be hauled to the yard and set over the hives.

The committee had already in mind such an outside protecting-case as you outline in your diagram above; and there is no getting around it, there are some good things about it. But such a case would assuredly have to be stored away in the summer, and, besides, it could not be made to answer for shade. It would not do to leave it on during summer, because that would destroy the bee-space; that is, the space *a*, in Fig. 1 above, would be anywhere from two to three inches—hardly enough to allow room for a super, and too much room without a thing in which the bees can store honey. It is true, in Fig. 2, that you can put on a super; but then, there is about a two-inch bee-space under it. For extracting, this can be remedied by using frames a little deeper. But you would then have two sizes of frames in the apiary, the one so near the depth of the other as to make it a nuisance. I do not see any practical way of making a water-table to be used in a regular hive, so that it will not destroy bee-spaces. Of the two arrangements, I think the outside protecting-case, such as I outlined in GLEANINGS some time ago, is much preferable. Reports now coming in show that it has already been in use, and is giving good satisfaction.] E. R.

MRS. AXTELL'S EXPERIENCE AT THE KEOKUK CONVENTION.

CONTINUED FROM LAST ISSUE.

I felt amply repaid for my trip to Keokuk, if for no other reason than to meet so many of our editors and bee-keepers themselves, and exchange the friendly greeting, some of whom I have known for many years, and been greatly benefited by reading their articles, but have never been permitted to meet before. Why, it would have almost paid me for going, just to hear Dr. Miller, who is the very embodiment of music, render his sacred and comic music. If any bee-keeper is troubled with indigestion, or the blues, let him attend these conventions and hear Dr. Miller render his side-splitting comic pieces (as Ernest calls them in GLEANINGS); and I miss my guess if he does not return home very much improved in health as well as spirits.

Among the supplies shown at the convention was a section foundation-fastener, which I purchased and brought home with me. I like it very much better than the Parker machine. It does its work much more accurately and more rapidly than any other process I have ever tried. I feel sure I can trust my help to put in starters with this fastener, which we never succeeded in having done accurately with other machines. This is Mr. Bittenbender's machine. I think he told me he had it patented, but I am sure no one will hesitate to expend 50 cents for so good a fastener when he has tried this. He is quite an enthusiast in his work. His wife was intending to come with him had not his little child got badly burned a day or so before.

QUITE A JOKE ON US.

The night after the convention closed, we thought to remain at the hotel where it would be quiet, rather than to travel on the cars, as we were going over into Iowa; but about 10 o'clock, dancing and music began, and it was kept up until about 2 o'clock in the morning. Doors banged every two minutes, it seemed to me, all night, and people kept up a continual tramp, tramp, by our door, until I thought sure I was in bedlam for once. We had just fallen asleep when the lady of the house called us at 4 o'clock to take the train west. As I passed along by farmhouses I kept on the watch for bee-hives, but saw none until we reached about the middle of the State, where we found one small apiary on the north side of a steep hill. Probably there were bees, but not in sight of the cars, until we reached Afton, and there we passed a beautiful little apiary of 50 hives. They looked real pretty, standing in straight rows, and hives so white and clean, on a side hill sloping toward the railroad track.

As our friends we went to visit lived in Afton, we found the owner of that apiary was Mr. W. R. Hunter. Mr. Axtell called on him and found him to be quite an enthusiastic bee-keeper. He had just invented a foot-power saw that Mr. Axtell said was ahead of any saw he had ever tried. With this saw he sat down. To work it he used both feet. He had applied for a patent upon it. He winters out of doors in double-walled hives, and seldom loses a colony if properly prepared for winter with good stores. His bees were all pure Italians except two or three hybrid colonies.

About a mile from Mr. Hunter lives Mr. Sype, who has about 50 or 60 colonies. They both reported a fair crop of honey from colonies that were in good condition in the spring. They both use a double-walled hive without chaff packing, which, he claims, is almost air-tight, or almost holds water on all four sides. The corners have tin strips tightly nailed on. He claims for them that they are almost a non-swarming hive, as the dead-air space keeps them cool, even in the hottest place; and just before they swarm he takes out the combs that have the most honey in, and removes the center combs full of brood to the two sides, and puts three or four empty frames with starters in, in the center, or uses empty brood-frames if he has them. With that treatment he said he seldom had a swarm; but he has not been in the bee-business many years, and it has now been several years since we have had many swarms; but let a heavy honey-flow come again, especially early in June or the last of May, and I believe he too would have a plenty of swarms.

If we can be prepared to care for swarms, and hive them so as to return them after the colony has lost its swarming fever (especially all colonies that are not very strong), I think it just as well to let swarm, as it seems to be nature's way; and a colony that has swarmed, and gets settled down to work, works with much energy and vim.

Our last shipment of honey to Chicago brought us 18 cents wholesale, and we are selling cut-out honey in new tin pans with glass shades over it, in Roseville groceries, at 18 cents, and take it in trade. MRS. L. C. AXTELL.

Roseville, Ill., Dec., 1890.

CANE SUGAR.

PROF. COOK TELLS US A GREAT DEAL ABOUT SUGAR OF ALL KINDS.

Since you ask me to state whether there is any difference between beet sugar and sugar made from cane, you must excuse me if I am quite scientific. I see no way to avoid it; but I promise to be as brief as possible, and to try hard to make all plain to all.

There are several tests of sugars: First, their chemical composition; 2, their reactions with various chemical reagents; 3, the way they rotate the polarized ray of light; and, lastly, their solubility and assimilability. Now, so far as we have any knowledge, the sugar from beets, from cane, from maple, and from the nectar of flowers, is precisely the same in all these respects. It is known as cane sugar, or sucrose. It has the following chemical composition: $C_{12}H_{22}O_{11}$. C stands for carbon, H for hydrogen, and O for oxygen. It will be seen that the H and the O are in proportion to form water, the symbol of which is H_2O. This is true of all the sugars and starch, as such substances are called carbo-hydrates. The same is true of lactose, or milk sugar. These sugars rotate the ray to the right, but do not decompose the copper salts. They are not as soluble, not as easily absorbed, nor as easily assimilated, as are other sugars. Thus we may believe that sugar from beets, from cane, and from maple, is identically the same. In the manufacture, beet sugar and sugar from cane are perfectly refined, or clarified, and so seem alike. Maple sugar is not so. The sugar is the same, but there are other substances present which modify the color and flavor. By the removal of these we should make maple sugar exactly like beet sugar. All water is precisely alike; but all *so-called* water is not so. Some is full of lime, some impregnated with iron, and some saturated with a mixture of saline substances; but these are foreign substances added. The water is always the same. The same is doubtless true of these cane sugars. As cane sugar will not act upon the copper salts, it must be reduced to glucose before it can be analyzed by the use of Febling's test. The bee does this with nectar in changing it to honey. We do the same with cane sugar when we eat it. Thus it seems very probable that honey is a safer sugar for one with feeble digestion than is our common cane sugar. Cane sugar is not so soluble, not so easily absorbed and assimilated, as is honey or other glucose sugars. We know this: for, if the same amount of cane and grape sugar be injected directly into the blood, at different times, it is found that but very little of the cane sugar will be used by the tissues, but most will be eliminated by the kidneys. Much more of the glucose will be appropriated. This proves that glucose is more assimilable, and explains why cane sugar must be digested before it passes to the blood. Liver sugar is like glucose in this respect. It is formed in the liver, and is probably just adapted for use or assimilation. The glucose, or grape sugar of the glucose-factories, is chemically the same—that is, all have this formula: $C_6 H_{12} O_6$. Yet I think this corn or starch glucose is not the same, else why do bees dislike it, even at its best, and why is it fatal as a winter food, when honey or digested cane sugar is perfectly wholesome? It might seem that the chemical composition would alone determine the character of such substances; but this is not the truth. Thus, fruit sugar, the most abundant sugar of honey, and dextrose, the sugar of starch, have the same chemical composition; yet one turns the polarized ray to the left, and the other to the right. All the glucose sugars are identical in chemical composition; yet, as we have seen, they are physiologically quite different. We see the same truth illustrated in starch, dextrine, and glycogen. They have the same chemical composition—$C_6 H_{10} O_5$; yet starch is insoluble in cold water, and gives a blue color with iodine; dextrine gives a brown, or purple color, with iodine, while glycogen, or liver starch, is soluble in cold water, and gives a brown color with iodine. While chemical composition is a sure test of inorganic compounds, it is not so with organic.

Thus we conclude, so far as we now know, that all cane sugar, of whatever origin, beets, cane, maple, or flowers, is the same, but that the glucoses, or grape sugars, though chemically alike, are not so. I think we may further add, that glucose, when of organic origin, like honey, liver sugar, and digested cane sugar, from any source, is easier of absorption, and a safer food than is starch, glucose, or cane sugar. While this last may not be positively proved, it is certainly a reasonable conclusion from the facts as explained above.

THE NATURE OF A SOLUTION.

One of the brightest bee-keepers of our country asks me if the centrifugal machines that are so effective in separating milk from cream might not be utilized in the separation of water from thin honey. Our friend, though an expert in all that pertains to practical apiculture, is evidently not informed as to the true nature of a solution. The reason that the centrifugal machine separates milk from cream is due wholly to the different specific gravity of the two. The same fact causes the lighter cream to rise to the top and leave the heavier milk below. In a solution the soluble substance is held by the water or other liquid, and all is liquid, and uniform in weight, except that the liquid is more than saturated—that is, it contains more of the substance than it can dissolve, and both will remain intimately combined indefinitely. The water or liquid will not rise to the top. For the same reason a centrifugal machine would be powerless to separate the liquid from the substance in solution. The sugar that settles at the bottom of the cup of coffee does so only because so much was added that it could not all be dissolved.

A liquid will hold only so much of any special substance in solution. If then the liquid is saturated, and we in any way reduce its quantity, we shall secure the substance previously held in solution. Boiling drives off a liquid as steam; hence by heat we thicken our honey or secure sugar from its solutions. By freezing we can also separate a liquid from the substance it holds in solution, as every boy who has worked in a maple-sugar bush well knows. Thus, to reduce our thin honey we have only to apply heat. If this latter is mild, we can thicken the honey just as well as it can be done by the bees in the hive. A. J. COOK.

Agricultural College, Mich., Dec. 15.

[Friend C., I am afraid you are getting in a good deal of chemistry for a good many of our readers. You have, however, brought out several valuable truths. First, we do not want maple sugar refined like beet and cane sugar, for then it would be worth no more. The maple aroma must be kept. Beet sugar and cane sugar are exactly alike because they are chemically pure sugar. Usually it costs a good deal of money to get any substance chemically pure. Even common water, when it is wanted chemically pure, is expensive. Since, however, the demand is so *great* for pure sugar, it is done on such a large scale by such expensive apparatus that the cost, after centuries of experiment, has become only very trifling, per pound. Water from wells and springs is never chemically pure, and seldom anywhere near it. Even rain water contains more or less foreign substances.

Since you have suggested it, I feel quite certain that *some kinds* of honey might be improved by the centrifugal machine. A good many of us have seen honey that was thin and watery on top, and thick and heavy at the bottom. We have used it, by drawing off from the bottom until it became too thin, and then evaporating what remained. Perhaps a centrifugal machine would not be of much advantage after all over gravity in the ordinary way.]

ABOUT GETTING OUT BEESWAX.

FRIEND FRANCE GIVES US SOME VALUABLE SUGGESTIONS IN WORKING WAX ON A LARGE SCALE.

For several years I have used a large iron kettle in which to melt up old combs, scraps of wax material, cappings, etc. But I have been very much dissatisfied with the looks of the wax. It was too dark in color. I studied over the matter a long while, to find out where the trouble was. I thought perhaps that I burned the wax, as the kettle was hung so the blaze from the fire came up all around the sides of it. The wax could easily be burned on the sides of the kettle above the water. I was always careful about having my fire small, and well under the kettle, to guard against burning on the sides. But, do the best I could, I think sometimes the wax got scorched some. But I found out that there was another reason why the wax was dark.

Last spring I thought I could spare some 300 lbs. of wax, and sold it to Dadant. He said to me, after he got the wax, that it could be a good deal nicer. Now, I did not like that kind of talk about my wax—not because it was not a fact, but because I did not know how to do any better; so I wrote back to Mr. Dadant for information how to go to work to make a first-class article of wax. I asked if a solar wax-extractor was what I wanted, etc. He wrote me that the solar wax-extractor was not what we wanted. He said it was too slow for the amount of work we had to do, but advised me to get a copper boiler made. He gave the dimensions of a boiler that he thought would be about right. It would cost, he said, six or eight dollars, and would last a lifetime. I went through our hardware stores to see what I could do. First, I bought a second-hand stove—a very large, flat-topped one, costing $6.00. Then I found two sheets of tin, very heavy, and sent off for copper to make the bottom. I had a boiler made, 26x24 inches, and 22 inches deep, with a good cover. It cost $13.00, and weighed, empty, over

40 lbs. Then I built me a shanty for a wax-room, and set the stove up in there, took off all the lids, set my boiler on, put in 6 pailfuls of water, heated it, and then began to pile in the combs to melt. My! how much the thing would hold! As the first melted, I put in more until the boiler was three-fourths full of water and wax. Then I took a dipper and dipped off the wax, about 30 lbs.; then as I had about all the wax out that I could dip off, I let the fire go out, and left it until the next day to cool off, when I found a crust on top of the water about 1½ inches thick that contained considerable wax. Below that there was a great amount of rubbish and dirty matter which I threw away. The top crust I put back into the boiler, to be melted with the next batch. The color of the wax was nice, a rich yellow.

One thing more I want to speak about. Mr. Dadant told me that it would be well to have a wire-cloth screen sunk into the boiler, over the old combs, to keep the impurities at the bottom of the boiler. As there are a great many light impurities that float with the wax, being nearly as light as the wax, these are the most difficult to get rid of, and I succeeded in doing away with them most readily by the use of this screen. All right; we shall have one for the next batch, and so we did. It worked well. The first time I used it the wax was nice. Then it was four or five days before I made another batch; and during that time my wire screen had got badly rusted. Not thinking of any thing wrong I used the screen as it was. But when I took off the wax I found it as dark as any that I had made in the iron kettle, all caused by the rust from that screen. So I did not use it again. I intend to get some copper-wire screens to use in place of the iron, as the screen is a big help.

Now, I find that iron rust will make wax dark—in fact, black—if there is enough rust. I find it pays to make nice wax. Mr. Dadant wrote me that he would like to get hold of my wax next time, if melted according to his directions. Well, after I had got through making wax for the season I wrote him that I had nearly 200 lbs. of very nice wax. I asked him how much he would give. He answered that he had a large stock on hand, and he did not wish to buy any more at present. I then sent the wax to A. I. Root, and asked him how the quality of the wax compared with the average. He wrote me, "Your wax was a good deal better than the average, and you see we have allowed you two cents a pound extra on this account." So you see it won't take long to pay for my boiler, in the extra price of wax. It pays to make a nice article. E. FRANCE.

Platteville, Wis., Dec. 6.

[We are greatly indebted to you, friend France. Although all you tell us is not exactly new, it helps us greatly in the arrangements for working on an old plan. We have discovered, as well as yourself, that iron rust is not a good thing for rendering wax. We have also found out that nothing in the shape of galvanized iron or zinc should be used about hot wax. It will turn the wax a peculiar dark green. Copper seems to be the only metal in common use that has no effect on hot wax. Tinware, after the coat has worn off, is almost as bad as the kettle, especially if it gets very hot. I fear you will find trouble in getting wire cloth made of copper wire. You can, however, get brass strainer wire cloth of almost any tinsmith, but it is pretty fine for your purpose, and rather expensive. Perforated copper would answer nicely. But wouldn't it pay you to put the residue under your wire cloth, in a press? You know a good many claim that they get an additional quantity of wax by applying pressure when the wax is hot. We are very glad to get information from anybody so well posted as the Dadants. Very likely it will pay bee-keepers with a number of out-apiaries to have a rig in some little shanty outdoors, for rendering wax. I am sure the women-folks will be ready to give us plenty of advice, and may be "three cheers" besides, when they see us take up our duds and move out of the kitchen, into the wax-house away off in the yard.]

MANUM ON A VISIT.

HE CALLS ON IRA BARBER.

Having promised myself the pleasure for several years of making Mr. Ira Barber, of De Kalb Junction, N. Y., a visit, as he is one of the most successful bee-keepers in the land, especially in wintering his bees in the cellar without loss, year after year, I have felt a desire to learn his method of wintering; and having received notice that a friend living a few miles from Mr. Barber was about to depart for the West, I thought it a good opportunity to "kill two birds with one stone;" therefore, on Nov. 8th I boarded the train; and after making my friend a few days' visit, on the 12th I landed at De Kalb Junction. Not having notified friend Barber on what day I would appear, of course he was not at the station waiting for me; but on inquiry I learned that he lived only two miles away; and on consulting a liveryman I found that $1.00 was his price to take me the two miles. The price was low enough; but I decided that I could save that much by going on foot, so I started; and in 40 minutes I was standing near friend Barber's hatchway, having just seen him and two other men go into the cellar with bees. As Mr. B. came out and looked at me a moment he exclaimed, "Hello, Manum! is that you?"

"I believe that is my name, Mr. Barber, even though I am some distance from home."

"Well, boys, this is Manum, the Vermont bee-keeper, and I guess we will do no more today. We have the bees about half in, and we can finish them some other time. I want to visit with Manum while he stays; and, by the way, how long *can* you stay?"

"I must return to-morrow, sure."

"Well, you are as bad as Ernest with your short visits. Did you learn that trick of him?"

"Now, Mr. B., don't compare me with Ernest. I am not editing a bee-journal nor manufacturing supplies. I am just simply a bee-keeper, and nothing more; and, besides, were I to remain here long I fear I should be homesick without any mountains to rest my eyes upon. Why! it looks strange here to me without a mountain in sight. Surely I would not dare to travel very far alone in this country without a good guide, as there are no mountains to serve as landmarks. Why! I should think your bees would get lost if they had to go far for honey. But, as I observed while coming from the station, you have clover so very plentiful here all around you, I don't suppose your bees are obliged to go out of sight of their hives at any time. Surely I never saw clover more plentiful than you have it here."

"Yes, Manum, we have plenty of clover here, white and alsike. Those large fields there across the way are all seeded with alsike; but this year there was no honey in it, hence I have had to feed my bees sugar to winter them. I finished feeding last night."

"What! feeding so late as this, and putting them right in the cellar? I have always thought bees should be fed early enough so they could cap over their stores."

"Well, that is the proper way, especially for outdoor wintering; but I have had no bad results from late feeding. Yet I would advise feeding a little earlier than this."

"Mr. Barber, how do you manage to feed with these single-walled Simplicity hives?"

"I feed with ten-quart milk-pans—here is one right here. There, you see I break up old comb into inch-square pieces for floats, and I put in what syrup the colony needs, and cover the syrup with the floats; then I raise up a hive, set the pan on the bottom-board—just at night—and set the hive over the pan, or, rather, the hive rests on the pan; and by the next morning the bees have taken up all the syrup; and by having pans enough I can feed pretty fast in that way. Now, Manum, my friend Charles Hallegas, who has about 100 colonies, wanted I should be sure to take you over to his place when you come; and as it is only six miles we have just about time to go and get back before dark, and I think you'd better take your camera along, as I think he will want a picture of his yard; so I will go and harness old Tom, and we will be off."

"I see you have stakes stuck down, with numbers on them, where you have removed the hives; why do you do that?"

"Those numbers correspond with the number of the hive that stood there. In the spring I set the same hive where it was this fall."

"Do you think that is necessary?"

"Yes, I do; for before I practiced it, and when I set out my bees they seemed to be lost for a day or two, there being much commotion in the yard; and some hives would get more than their share of bees, while now all is quiet after an hour or two."

"What are these machines with these great tin drays? They are something new to me."

"Well, Manum, this is where I feed in the spring. You see, I have these great boxes made with a small door at the side, where I put in a lamp, and these trays are set over to close the top, and I pour my sugar syrup into them. They hold about 10 gallons each. Then I put in these wooden plates, made by tacking together narrow strips in the form of a rack. My lamps keep the syrup warm, and the bees come here in swarms to take the feed."

"Well, but are you not feeding your neighbors' bees also, as well as bees in the woods?"

"Well, I presume so; but I find this the best way for me to feed in spring, as it stimulates breeding better than any other way of feeding that I have tried; but the feed should be very thin. Let us be off."

On the way to Mr. Hallegas' place, Mr. Barber says:

"There, Manum, you see all those fields are covered with clover; and how far should you say it is across that meadow there on the left?"

"Oh! I should say three-fourths of a mile."

"You are wild. It is all of a mile and a half, and this one on the right is all of one mile, so you see I have a large range near by."

"So I was right, Mr. Barber, when I said your bees must have plenty of forage within sight of their hives. Now, if I had such a location as this I could get rich in two years—two good seasons, I mean. How long have you kept bees, Mr. B.?"

"Since 1852. My brother and I started with four colonies in box hives; and I had since, at one time, 500 colonies, but now I have only 140."

"During these 38 years have you ever had as many poor seasons in succession as the past four or five years have been?"

"No, Manum, I never have. Two poor years running is the most; but this terrible setback does not discourage me in the least; and, don't let it discourage you, for there is surely a good time coming, and I feel very sure that next year will make us all happy. Why! just look at the growth clover has made this fall; see how rank it is; and, furthermore, next year is our basswood year. So, then, my advice to you is, be hopeful, and ready for a large honey crop."

"Well, Mr. Barber, your talk encourages me very much indeed. I had been of the same opinion; but to hear it from an old bee-keeper, one with such an extensive experience as you have had, is surely very pleasing."

"There, Manum, the next house is where Mr. Hallegas lives."

Approaching the house I saw two men standing in the yard, and I heard the older one ask, "Who is that with Barber?"

"Well, father, that is Manum that you have heard me speak of."

I jump from the carriage, and Mr. Hallegas takes me by the hand, and says:

"Well, Manum, when I met you at the convention at Albany I never expected to see you here; but I am very glad to greet you."

"You see, Mr. H., I am everywhere, like a poor season. Where are your bees?"

"Right out here, back of the house. Have you come prepared to make a picture?"

"Yes, sir, if you would like one."

"Yes, I should; but step into the honey-house here, and see my new clamp. There, what do you think of it?"

"It is a very good clamp, though quite similar to Crane's, Wright's, and several others, only yours is not complete. For me to use, I would either use a screw or wedge to hold the sections in place; and I should want a groove here and one there, and insert a tongue to rest the separators on. How many bees have you, and what are they?"

"I have 96 colonies, nearly all blacks; and I find the blacks do better in a poor season than the Italians—at least, mine do."

After a short but enjoyable visit we return where Mr. Barber serves up a fine supper. I will say here that he does his own housework, having buried his wife four years ago. He has done his own cooking since; and I assure you, Mr. Root, that the ladies are not plentiful who can outdo Mr. B. in the kitchen. The evening was spent in talking on various topics pertaining to bee-keeping, such as chaff hives, single hives, strips, and full sheets of foundation, as well as the much-talked-of thick top-bars and broad-end frames. Finally the subject of locating out-apiaries was brought up by Mr. B. asking:

"Manum, how far apart do you think out-apiaries should be located so they will not encroach on each other's territory? and do you have them all strung along in one direction, or do you locate them all around your home apiary?"

"Well, Mr. Barber, owing to the fact that there is a high range of mountains on the east of me I am obliged to locate my apiaries northwest and south; and now if you will get me a piece of paper I will make a pencil sketch of my apiaries and the surrounding country; then you can see for yourself how I am hedged in by hills and mountains."

"See here, Manum, did you know it is after 11 o'clock? It is time we were in bed. You can make your map in the morning while I cook our breakfast."

Bristol, Vt., Nov. 28. A. E. MANUM.

(To be continued.)

ERNEST'S NOTES OF TRAVEL.

OVER THE MOUNTAINS AGAIN.

I promised, some time ago, to give you a view of O. R. Coe's hotel and mountain surroundings at Windham. In response to this, you see he has loaned me an electrotype showing his place. The engraving hardly does justice to it. In fact, no effort of man can adequately represent, on paper, mountain scenery as it is. Windham is a very pretty mountain town, free from malaria, as a matter of course. At the time of our visit, one or two parties from Florida were stopping here to get the malaria out of their systems; and it was coming out, too, with a vengeance.

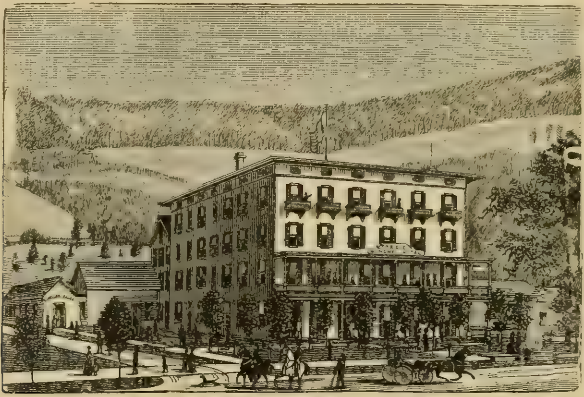
I should have been glad to spend a week at this delightful place; but I had to hurry away after I had been there a couple of days. I longed for the privilege of climbing up the mountain in the rear of the hotel. While I was there, several ladies, unbeknown to anybody, had made the climb, and, for a wonder, had got back safely without getting lost. It is hardly wise for strangers to attempt to go up the mountains unless accompanied by a guide, especially if there be no footpath or roadway. Indeed, our friend Coe, just the day before we arrived, had himself, after a residence of many years in this region, got lost on the mountains. He had taken a party of tourists up sightseeing; and after directing them to go up a familiar pathway, he himself concluded to take a short cut across through the woods. He lost his bearings, and for two or three hours he wandered about not knowing which way was north. He climbed a tall tree, looked over, and then learned where he was. On reaching the company they were much alarmed because of his long absence; and, not daring to attempt to go home without a guide, they began to feel themselves in a predicament indeed. May be they feared the bears.

THE MOUNTAIN BEARS.

Yes, there are bears on these mountains, but they are harmless, and will run from the *genus homo* before the latter can even recover his consternation. They are rarely seen except during winter, when they are kind enough to come down and carry off a sheep or a pig or two for the farmer—a kindness which the latter for some reason or other does not appreciate.

WHY BOX HIVES WILL WINTER BEES SOMETIMES WHEN FRAME HIVES WILL NOT.

Mr. Coe's honey-house and winter repository, as well as the apiary, are in the rear, just back of the buildings, and therefore they do not show in the picture. You will remember that this is the apiary where the bees die every winter, although box-hive bee-keepers all round about are successful in wintering. Mr. H. B. Harrington, otherwise known as "Neighbor H.," told me he thought he could solve the trouble. Said he, "In box hives you will notice that the combs always radiate from a common center, something like the spokes of a wheel; and there is a central passageway through the mass. In this opening the bees cluster and radiate from the center to the outer edges of the hives, as they run short of stores. In the movable-frame hive, the modern bee-keeper spoils all this; and in Mr. Coe's case the bees were obliged to pass up and over the combs, and consequently the bees in box hives would survive while those in his modern hives would die."



O. R. COE'S MOUNTAIN HOME.

This same matter has been brought up before, I believe. I am glad to give it here, as it suggests a very probable cause of Mr. Coe's winter troubles. I myself have never dissected box hives enough to know just how combs are built; but Mr. Coe can tell if this be true. My impression is that they are built just about as Mr. H. says.

A VISIT TO THE DADANTS.

Well, now, I am going to jump from the eastern part of York State clear over to the valley of the Mississippi, and I can do it on paper, I am happy to say, in a good deal less time than I can do it wheeling it across the real territory.

At the close of the convention at Keokuk, we were invited by the business men to ride over and visit the Dadants, ample conveyances being provided for the occasion. We crossed the immense railroad bridge at this point, something over—I don't dare tell now; and after crossing we reached the suburbs of Hamilton, a town of 1500 inhabitants. The peculiarity of it is, that it is a very long town. I think you can ride on one road for a couple of miles without getting out of its suburbs. After a very pleasant drive over beautiful roads we finally reached the home of the Dadants. At several points along the route I wished for the Kodak, which I did not have on this trip. With this little instrument I could have shown you a line extending perhaps a mile long (it might have been only half that), of teams carrying bee-keepers to the largest foundation-factory in the world.

On arriving at the Dadants' we hopped out and were freely invited to go anywhere and everywhere we pleased. Mr. C. P. Dadant told me that they had no "secrets;" and although I believe I represented their most formidable rival in a business way, he very freely and kindly showed me all their kinks of the trade; and before I forget it I want to say they have got the business down to a fine art and a most perfect system. Every operation or method seems to have been wrought out by careful study, both as to economy of time and labor — a condition in which employes and employers are interested.

When we went into the shops the workmen (a nice set of people they were) were turning out foundation in full blast. They are paid so much a day; and then, as an additional stimulus, they are given a bonus on the amount of foundation they turn out; that is, they work on the co-operative plan. This is so arranged that it is to the interest of the employes to turn out not only *quantity* but *quality*. Although the men worked rapidly, yet there was painstaking care exercised through it all. If there was a doubt as to whether a sheet would be suitable, it was cast into the waste, to be remelted and made anew; and I do not much wonder that every inch of the Dadants' foundation is equal to the sample sent out. I was surprised, however, to see that they should turn their mills by hand power, when steam is so much more expeditious. But then, for all that they manage to turn out *80 tons a year*.

The rooms were crowded with bee-keepers, to witness all the different operations. In one corner I noticed quite a circle of people; and peering over their shoulders I noticed that a couple of Mr. C. P. Dadant's little girls were what we call "papering" foundation; that is, they were putting a sheet of paper between the sheets of wax. I took out my Waterbury and began to time them, for their hands moved so rapidly it was a difficult matter to follow their movements. If my memory serves me rightly, they papered about forty sheets a minute; and if a big crowd had not been looking on, they might have averaged a sheet a second. These two do not do this during the busy rush, but they *know how*.

After we had wandered all through the different apartments we were invited to the honey-house, and there took lunch, after which quite a number of us could not refrain from going out and looking at those large Dadant hives. No doubt for their locality, and for extracted honey, these big hives are decidedly an advantage, and it would be hard to conclude otherwise, in view of the tons of honey obtained.

As it was beginning to be train time, the teams were commencing to load, and off the long train of conveyances started. It was my pleasure to be of the party with C. P. Dadant. Just before getting into the buggy, an old negro brought the horses and hitched them in. I could not help noting in particular the frank, honest look on his face. He seemed to know of the different bee-keepers, and Mr. Dadant introduced him to me as "John." He has been with them a good many years, and is one of those faithful, trusty employes whom it is a pleasure to have. After Dr. Miller and I got into the buggy, the venerable Charles Dadant (and it's a genuine pleasure to look into his genial face) came forward and pressed us hard to stay over; nothing would have furnished me more enjoyment personally; but as usual I had to make time.

He is indeed one of the veterans in the business; and now at an advanced age (73) he seems to retain all his bodily vigor and strength of mind. We finally bade our old friend good-by and started off for Keokuk, where we all took our several ways.

QUEEN-REARING.

DR. MILLER TELLS HIS EXPERIENCE WITH THE DOOLITTLE AND ALLEY METHODS.

I tried Doolittle's artificial cups for queen-cells last summer. I made perhaps 200 of them. I tried to follow his instructions to the very letter; but after leaving them in the care of the bees for 24 hours my spirits were saddened to find the bees had emptied every cup and cleaned it out bone dry. There were a few exceptions in which the grubs were kept a day or two, but only two that continued to maturity. These two were, I thought, the nicest I ever saw—the cells so perfect, so easily detached, no daubing in cutting them out, no extra comb about the base. I'd like to know what the trouble was. Possibly the very poor season had something to do with my failures.

With the Alley plan I had less trouble; but even with that there were more failures than in former years. A great advantage of the Alley or Doolittle plan over that of simply taking away a queen and letting the bees have all the brood to start queen - cells, is that you know something about, and have some control over, the grubs used. With several frames from which to select, the bees *may* use larvæ too old to make good queens. Still, I must say that my own experience in this respect hardly corresponds with the impressions I had gained from reading. As a general rule, where a queen has been taken away and the bees left to their own devices, no queen has hatched until 12 days after the queen's removal—in some cases 11 days after, and in rare cases 10 days after. I don't like, however, to run the risk of these rare cases, and there is another factor which enters into the problem. Suppose a queen hatches 12 days after the old queen's removal; are we sure that the bees started the queen-cell just 4 days after the egg was laid—in other words, just as soon as the queen was removed? You see, they may not have discovered their queenlessness for some little time. At any rate, if they have brood in all stages you don't *know* what they're using.

With the Doolittle cups you may know to the hour just how old your grubs are, *if* you get the bees to respect them. With the Alley plan you can also know to the hour the age of the grubs given. Suppose at noon, on Monday, you give to your best queen a brood-comb without eggs or brood where you think she will lay in it. On Friday, at noon, take away that comb and you know to a certainty that there is nothing in it older than four days from the laying of the egg. Take some of it and use it for starting cells on the Alley plan, and you may look for queens to hatch in 12 days. What chance can there be for failure?

Well, by that plan I have raised some of the finest queens, and also a few of the very poorest. Suppose that the bees start cells as soon as the material is given them, and that all are of the same age, I should expect very few poor queens. But queenless bees do not always start all the cells into queen-cells as soon as given. Some of the grubs are likely to be continued as workers for two, three, or four days. Then, having got their queen-cells fairly under headway, they conclude they want to start some more; and if they have nothing but grubs four days old—or seven days from the laying of the egg—these will be used. So they may use grubs so old that there is not time to feed them up into good queens.

A remedy in this case lies in destroying all grubs that are not started as queens within 24 hours, perhaps giving younger brood in their places.

I feel sure of good cells if they are started in strong colonies; but after the cell is sealed, is it any better off in a strong colony than in a nucleus, *if* it is kept just as warm in the nucleus? There may be a difference. At any rate, I look for a queen to lay a little sooner in a full colony.

If, however, two nuclei be in a double hive, and a thin partition between them, I do not see why a queen may not be raised just as well in either as if the partition were taken away and the two thrown into one. And if that partition is no detriment, may not more than one partition or division-board be used without hurt, thus increasing the number of nuclei in the hive?

GETTING RID OF LAYING WORKERS.

Very often it isn't worth while to fuss much with a colony having laying workers. It's likely to be a weak thing at best, the bees mostly old; and if honey is yielding well, I've had no trouble in distributing the combs and bees to colonies needing them.

Lately I have found a way to get rid of laying workers in a very easy manner. I take a young queen just hatched, or one that I have just pulled out of a cell; drop her right among the bees, and in the usual course of time I find her laying, and the laying-worker business is stopped. I have not had a single failure; but I have not tried enough cases to say that it will always succeed. C. C. MILLER.

Marengo, Ill., Dec. 6.

[Friend M., your italic *if*, when speaking about putting cells in a nucleus or in a strong colony, is just where the point is, especially if you have cells started very early in the spring. The nucleus may seem all-sufficient to cover and keep the cell warm, until a heavy frost or a cold storm comes along. Then I think the queen is oftentimes injured by the cell being chilled or partly chilled. I am sure your plan of getting rid of fertile workers will not always work. When we first got our queens hatched in the lamp-nursery, we fondly hoped that it would help us to get rid of fertile workers. But on several occasions we saw the bees cling to their fertile-worker queen, and refuse to acknowledge the one newly hatched. She would get out around the entrance and "go dead," sooner or later.]

HOW TO BE YOUR OWN CARPENTER AND JOINER.

SOME PRACTICAL HINTS TO THE YOUNG WOOD-WORKER.

The above sounds something like the title of a book, does it not? Well, I am not going to write a book on carpentry and joinery—just yet, at least, although I have often thought that I should like to do it. Several things have reminded me of the importance of such a work just lately. By the way, did you ever have a carpenter or a joiner work for you? and did you ever feel disgusted because he took a great amount of time, and made a botch of his work after all? If you have not, perhaps your *wife* has had some such experience. Yes, very likely you have at some time in your life tried your own hand at carpentry; and may be your wife has tried the same thing. Perhaps you have *felt* your own helplessness in so doing. Well, I have passed through these experiences again and again. In later years I have had a good deal of experience in hiring carpenters and joiners, and wood-workers generally; and I have been many times greatly disappointed to find that experienced wood-workers, many of them, had never learned common-sense short cuts, or little "tricks of the trade," that enable one to make very pretty-looking work, oftentimes, without very much time or expense being required. I have so often felt this, that it occurs to me that I should like to give a few simple hints to those who like to do their own carpentry.

In the first place, you need some tools, although not very many, for most ordinary jobs. These tools need not be very expensive, nor very elaborate; but they must be in good working order. In fact, you must *keep* them in good working order; and you must learn better than to run your saw or plane against nails. Do not be guilty of *such* blunders, whatever you do. In the first place, you want a good pocket-knife, and you want to keep it perfectly sharp. How many of the hundreds I have working for me, do you suppose, have a sharp knife in their pockets, whenever I tell them what is wanted? Why, lots of great big men and tolerable workmen do not have any knife at all. Others have a knife that is so dull it is almost as good as none. If you find your knife dull when you are in a hurry, and no whetstone is near, go to the nearest stone you can find, of any sort. I sometimes sit down on the doorstep and give a knife or other tool a rough sort of sharpening that will make it take hold of certain kinds of work even better than a fine smooth edge. Even garden tools can be greatly improved, often, in a very few minutes, by sharpening on the nearest sandstone. A good many say they can never *keep* a knife. Why, my friend, you ought to be ashamed of yourself. If you can't do any better, do as I do. Put a ten-cent knife in each pocket. If you lose one you will have another; or if you lend one you will have another. After your pocket-knife you want a saw, or, rather, two saws. Almost any sort of saw will answer if you keep it in order, or away from nails or gritty lumber. Then you want a good hammer and a good assortment of nails. Be sure you do not spoil what might otherwise be a good job by driving a big awkward nail into a light piece of wood. When you get a hammer that suits you, with a good assortment of nails, you want to practice until you can drive a nail exactly where you want it. If the nail is right, and the hammer is right, and the man a hold of the *handle* is right, the nail can be made to go within a hair's breadth of where it ought to go. You also want to learn by experience (by looking at the nail and looking at your work) when there will be a liability of splitting. I can endure almost any thing better than boards split up by unskillful nailing. If there is any doubt about it, have a brad-awl handy, and make a path for your nail so it *must* go right. A great many times, screws and a screw-driver must take the place of nails. You also want a good sharp hatchet, to be kept sharp like the saw; a chisel or two, and a couple of planes. In these days, when mechanics handle nothing but planed lumber, it is very seldom that there is any need of planing rough boards by hand. Still, you want a smooth-plane and a jack-plane. Then you want a try-square, a carpenter's square, and a bevel square. The two former must be accurate. If they are not so when you buy them you must file them until they are accurate. See directions in the A B C book. Then you want a sharp lead-pencil in each pocket. For very accurate work, use the point of your knife instead of a pencil. Learn by practice until you can saw so close to the mark made by the point of your knife that the path of the saw is just level with the knife-cut, after your board is cut off. Never saw a board off without a mark made with your try-square. Lay the try-square on the *edge* of the board, so as to have it square both ways. Always plane the edges of your board, and lay on your try-square to see that they are planed squarely. When carpenters put up shelves or other work, leaving the rough edges of the boards unplaned, it vexes me exceedingly. You can do a rough job quicker with planed boards and planed edges than you can cut and slash without rule or pencil, simply because you are in a hurry. Haste not only makes *waste* in carpentry, but you will find that "lazy folks" oftentimes "take the most pains" eventually.

Where you are to hitch on to other work, some judgment and discretion are necessary; but as a rule I would make the new work level and plumb. Keep constantly by you a plumb and spirit-level; and when you put up a shelf, door-step, or any thing else, that is supposed to be level, make it absolutely level—level north and south, and level east and west; and if any thing is supposed to be perpendicular, have it absolutely so, putting the plumb on both sides. Few carpenters will take the pains to do this. Many accidents, and much loss of life, even, have occurred by having steps awkwardly put up. If what you do is put up square and level, you will have the satisfaction of knowing that your work is right so far as you have gone; and if at any future time other work is to be added or attached to it, it will be plain, clear sailing.

Do not go to cutting up your lumber until you know exactly what you want and what you are going to do. Whenever I set a new carpenter at work it is always interesting to me to watch him, and see if he will not take more time in remedying blunders than he does in doing the work. A man who can go straight ahead, without balk or blunder, will accomplish a surprising amount of work in a day. But men who can do this are very scarce. This is why it often pays to employ a competent architect, and give him five per cent of the whole amount of money invested, when the job is of any magnitude. It is his business to lay the work out so it can be pushed along rapidly by ordinary mechanics, without running into any snags.

Have your lumber all dressed to an even thickness. Insist on this at the planing-mill; that is, have all your inch boards dressed to the usual ⅞; and have your two-inch stuff also dressed to an even thickness. If you are using scantling, have them all sawed or dressed so all are alike. It will pay you to have it done before you commence. When your lumber is all on the spot, sort it or classify it so you know just what you have. Before cutting, decide what lumber is to be used to the best advantage for a certain place. Never cut off a board or stick until it must be cut off. Over and over again, men will go to work and saw off a stick when there is no need of sawing it off at all, and then discover that they made it too short, or spoiled it for the work intended; and then there is some botch-work in splicing it. A great many times the stick or board can be put in place, or nearly in place, before it is cut at all. Cut one end, if it must be cut, and then take your stick or board and nail it in place temporarily, leaving the nails projecting so they can be drawn with a claw-hammer. Almost every carpenter I get hold of will nail things in fast, driving the nails clear down, and then discover that the board has to come off again. He will say that he can get it off again without splitting the board; but the board *is* split, and made ungainly-looking, if not spoiled, before he gets through.

How many carpenters pound their work all up with their hammer, by pounding a nail after it has gone clear home! One of the first lessons my father taught me was to avoid pounding up nice soft lumber. Strike your last blows so the nail is down level, without leaving a single hammer-mark.

Sometimes, when you are undecided just how things are going to come out, you can put your work almost all in place by means of nails driven part way in; then if a change is to be made, it can be made easily and nicely. After every thing is in place, just as you want it, and it all looks right, *then* drive the nails home to their places.

Do not measure with a rule or square, and then go and cut your stuff, saying it is so many feet and so many inches long. Why, I have seen a great pile of lumber all cut up wrong, because somebody made a mistake of a quarter or half an inch. Instead of using the square or rule, have some light strips of wood. Lay a strip on the place to be measured, and mark it with your pencil, or cut a notch with your knife.

Do not think of going to work without a ten-foot pole. When you get it all cut up or marked up, take your plane, plane it off, and mark it over again.

In taking dimensions, where you can not get a stick or pole in handy, say in getting the distance between two walls which are four or five feet apart, take two strips, say two pieces of lath. Lay them against each other, and slide one along the other until it touches the opposite wall. Now drive a nail through them, or, better, two nails, and you have the exact distance. It is taken quickly, and there can be no possibility of a mistake. If those who have worked for me, had, in taking dimensions in years past, done this, it would have saved me hundreds of dollars. Where somebody takes a rule or square, and measures, and then says it is so many feet and so many inches, it seems as if such a one *always* makes a mistake, especially when I am around. Oftentimes the dimensions are given to somebody else, and the second man does not understand.

If you are sending for a pane of glass to fit some place, give the boy two sticks to take to the hardware store. Tell him the glass is to be as wide as one stick, and as long as the other; and if you cut your sticks exactly right, your glass will be exact, and the same way in taking the dimensions of any thing. It is quicker, and absolutely safe. Many mechanics seem to think cutting things wrong, and sending boys for the wrong thing, should be counted on as a matter of course in every day's program.

Do not be in haste to saw off every thing. Many times people waste their time and strength in sawing off sticks or boards that do not need to be sawed off at all. They do it on the same principle that the girls did who were wasting their time in scraping and peeling labels from some glass jars. When I asked them why they wished to get the labels off, they said they wanted to put on some new, fresh-looking ones.

"Well," said I, "why not put the new labels right over the old ones, letting them be where they are?"

Nobody could answer or give any reason, and yet they were consuming valuable time.

A great part of carpenter work is simply to please the eye. It does not matter how your boards look where the work conceals it. By the skillful use of cheap slender molding you may make a botched job look artistic. Let the molding cover the joints and general unsightliness. I saw a very pretty ceiling, made of boards one foot wide, dressed on one side. These boards were not even sawed off at the ends, and the cracks between them were, some of them, an inch wide; yet strips of molding, put on skillfully, covered all the cracks and joints, and divided the ceiling into pretty oblong squares.

THAT DARK HONEY FROM ARIZONA.

PEACE AND GOOD WILL COMING OUT OF SOME OF OUR TROUBLES.

Perhaps every reader of GLEANINGS took a deep interest in Our Neighbors in our issue for Dec. 1; and I am very glad to see that all parties concerned have taken hold with a will to straighten up, so far as may be, the damage done by letting honey go out on the market labeled as a better grade than it really ought to have been. The first letter comes from the brother who inspected the honey when it was loaded on the car.

Dear Brother:—I call you "brother" because I think you are a brother in Christ, from the acquaintance I have had with you through GLEANINGS. I do not know when I have felt as bad as I did last night when I read in GLEANINGS of Dec. 1 about the honey that G. B. Shelton received from you that came from Phœnix, Arizona. I can't see how there could be any honey in the car like that represented by Mr. S. I am inspector of the Bee-keepers' Association of Salt Run Valley, and I tried to be honest in the matter; for if there is any thing that I do love it is justice. This is a great honey-producing country, and we have more honey than the local market demands; and we are compelled to find a market in the East for our honey, and it behooves us to sell it only as represented, if only from a business standpoint, leaving out the honesty and justice of the matter.

We load a car in two days when we ship. All the bee-keepers of Phœnix load the first day, and then the car is run to Tempe and finished up. I take off the screw cap on the can, and examine the honey as to flavor and color. I use a pocket-knife with a blade about three inches long. I had others, who would not be interested in the person's honey that I was inspecting, examine the honey as to color and flavor. I confess that I did not look at every can; but when I looked at most of the honey, if it was of a uniform grade I would ask the party whether the lot was of the same extracting, and he would answer yes. Then I would grade it 1, 2, or 3, as the case might be. I fought against any honey being shipped in *old cans*, but was ruled out for this year.

If the cans were badly rusted inside it would make the honey darker, and give it a bad flavor, if it had become granulated and was melted in the can. Some one of the shippers may have been mean enough to put bad honey in the bottom and good on top; but I trust not. I want you to find out, if you can, whom the honey belonged to, and let the association know all about it. W. L. OSBORN.

Phœnix, A. T., Dec. 15.

Here is another, written in an equally kind and fair spirit, from our friend Shelton, who is, perhaps, the principal sufferer:

Dear Friend:—Your very kind letter of the 12th inst., requesting me to make out my bill for damages, was received in due time, and I should have answered sooner, but I have been very busy. Now, my kind friend, I do not see how I can make out a bill for the damages on this dark honey, for I can not tell just what my actual loss is. I do know, however, that I care very much more for the injury done my reputation in the honey-business than I do for the actual loss in money. I will try to make all satisfactory with the men I sold the honey to, but I feel sure that I shall never be able to fully satisfy them and regain their confidence.

I must in turn thank you for your very kind and Christianlike letter, and I do try to be, and hope that I am, worthy to be called your brother in Christian love.

Brownsville, Pa., Dec. 22. G. B. SHELTON.

The following is from the corresponding secretary of the association in Arizona:

Friend Root:—I have been a reader of GLEANINGS for three years, and have not written a line intended for publication in its pages; but now the time has come for me to have my say, which will be principally in defense of Arizona honey, and of the Bee-keepers' Association of Maricopa County. I have read a short letter written by you to our recording secretary, after the receipt of the second car of honey from us. I have read carefully, *three times*, your sermon in GLEANINGS of Dec. 1st—to be sure that I comprehended fully the gist of the matter there set forth. I am free to say that I consider that sermon one of your best, in the way it connects religion with business, and pleads for fair treatment of customers in trade. I think I can comprehend why you should seem to write under a fit of "the blues," after receiving those discouraging letters from G. B. Shelton and the firm at Cleveland, O. When a man's honor is at stake, it *is* something to be worried about. I must confess that I have felt some satisfaction in the reflection that "misfortune loves company." I knew you were having some trouble with the first car of honey from Arizona; and when I learned that you had received a whole car of comb honey from one man, friend Ball, of Nevada, I thought to myself, "Now Bro. Root will have clear sailing. This car is uniformly of even grade and high quality, and it will go off without trouble, at a high price, and the buyer will be well pleased with his goods."

Imagine my surprise to find that some of *friend Ball's* goods were rejected and returned, which goes to show that some of us who are compelled to combine for shipment, in order to get our honey on to the market, do not have *all* the trouble that comes from dissatisfied customers.

I must say, too, that, when I read your sermon the *first* time, I thought, "Bro. Root is wrong in making public through GLEANINGS that which could have been better settled by private correspondence." I conclude that you thought it well to give the matter a thorough ventilation for the good of the shippers in particular, and the honey-trade in general. If so, the thing is *out*, we are all *in* for it, and here goes.

In the first place, no complaint can lie against the Arizona shippers of comb honey in either car on the ground of willful dishonesty in putting the white sections on the outside to show off, while the dark were put in the middle of the crate. No glass crates have been used. We had to use such crates as we could make or get made here, without glass. If any mistake was made it came from imperfect grading *without* intent to defraud. There was no inspection by our association inspector. Each man crated his honey to suit himself as to his own notions of what would best suit the case, expecting the honey would be sold on its merits. Some shippers in the last car marked their crates with "light" and "dark," as an indication to A. I. Root's men where they might look for the lightest honey and where for the darker shades, expecting, however, that such care would be taken at your end of the line as would enable you to know just what kind of honey you were sending to a customer. I am quite sure that I said in my letter accompanying the invoice of the last car, that we expected the honey to go on its merits, and any expense necessary to put the honey on the market in a fair and square way would be cheerfully borne by the shipper; and I say now again, grade, assort, inspect, and sample at *our expense*, sufficiently to give every buyer as nearly what he buys and pays for as human diligence can provide.

In regard to extracted honey, I am free to say that I believe no one of our shippers attempted any fraud or sharp practice on anybody. Every thing was left to the inspector to grade according to his best judgment. One customer says our inspector must have "an elastic conscience." In defense of W. L. Osborn, I want to say that those who best know him will, to a man, resent this charge. I believe there is not a more honest or conscientious man in Maricopa County. He desires to do the square thing every time.

Furthermore, we do not claim that the inspection was faultless. We admit its defects. It is quite impossible to examine 500 cans of honey from 20 different shippers, and pass upon its merits as to color and flavor, critically; load and invoice it in one day, the inspection to be made by one man. Yet this is what we attempted to do. Of course, there was force enough at hand to do the nailing, handling, and marking; but the rub comes in on the *tasting*, to determine flavor. I know of no way of determining flavor except by tasting. By the time a man has tasted honey two or three hours his tongue becomes so demoralized that all samples taste alike.

It is not necessary to go into details further as to what might happen and possibly did happen between the carelessness of the shipper on the one hand and the exacting demands made upon the inspector on the other. Suffice it to say, that every can went from here with the inspector's certificate pasted upon it, which was supposed to show what kind and grade of honey it contained. Most of it went as first-class, some second, some third.

Now let us come to the real gist of this honey trouble. We desire to know whether Bro. Shelton really got that bad honey that he complains of out of the first carload from Arizona. If he ordered honey by sample, why did he not get that which was as good as the sample? Furthermore, we want to know whose honey Mr. Shelton got, if it came out of our carload. We want to know whose honey it was that created adverse criticism from *other* customers, if any. This thing should be fathomed to the bottom. If you kept track on your shipping-book, of the marks on the cases as they were sent out, you can, by comparing with the invoice sent from here, determine the name of the owner. We have a copy here which can be used in an emergency. Follow it up and report. We desire it for two reasons. One is, to do equity in case any one has been wronged to the advantage of the shipper; secondly, to teach a lesson to him who has erred, for the benefit of his future work as a bee-keeper.

And now as to the future. Our bee-keepers' association has come to stay. We can not afford to do without it. Owing to our situation we are compelled to market our surplus product in carload lots. Not many of us are large enough producers to load a car alone; but by combining we can ship out of this valley several carloads during the season. If there are defects and objections in our plan, we propose to go to work to overcome them so far as human ingenuity can avail. In one letter some time ago you said we could succeed best to market our goods through commission houses in large cities, where the buyers could inspect personally the goods they bought. While there may be some force in this point, I will say that we desire to encourage and foster that kind of trade made by samples. We believe it can be done to the satisfaction of both buyer and seller, in most cases. At our bee-keepers' meeting on Saturday I said that our association had now reached a critical point in its history. We commenced shipping late this year, under somewhat difficult conditions. We did the best we could, learned some lessons, struck some snags, and are now getting the ebb from the first tide of success. I made the point, that it would prove to be wise to commence now and lay plans for our work for the year 1891. The subject was referred to our board of five directors, to be assisted by an advisory committee of three from stockholders. The committee will get to work soon and do their level best to lay plans for the benefit of our members, and for the consumers of Arizona honey everywhere. I can not suggest all that will be done, but will indicate something which I believe will be as follows: Require the universal use of new cans, each can to have upon it the name of the shipper or producer; also the inspector's certificate, stating kind and grade; similar marking as to kind of honey on the outside of the case; stencils to be used for marking cases and crates; comb honey to be marked with producer's name, and probably graded as to color, etc. Neatness of package, care in straining honey, accuracy of weight of extracted honey, notation on crates of gross, tare, and net weight of comb honey will be insisted on; also some plan for promoting more thorough inspection.

Any suggestions from A. I. Root will be gladly received. J. H. BROOMELL, COR. SEC.

Phœnix, Arizona, Dec., 1890.

[Many thanks, dear friends, for your fair, kind, and frank letters. There certainly can be no trouble in adjusting every thing pleasantly where a disposition of this kind is shown. We did have the name of the producer on the label of those cans; but perhaps we have had publicity enough so that all may see the lesson that it so plainly teaches. Light-colored honey is almost always pleasant-flavored honey, unless there is something so extraordinary as to give it a bad taste; and I fear these rusty second-hand oil-cans may have something to do with it. The trouble is, somebody will let a can go that has not been perfectly freed from the taint of oil. There is a difficulty, as we have found here, in tasting such a large number of samples of honey; but I do not believe it is necessary to taste it *all*. If poured into a little vial, or even into a saucer, the color and transparency will show pretty plainly the quality; and if the honey is nearly all good, when a sample of bad taste shall present itself it will be readily thrown out. The white-sage honey from California is so perfectly alike all through that there is no need of tasting or sampling. You may take any can you choose, and it is exactly like the rest of the carload. This is certainly a great advantage when such a state of affairs can be secured, and I do not know why alfalfa honey should not run as regular—that is, if a locality can be found where nothing else is mixed with it.

Here is something further in regard to the matter:]

IS ALFALFA HONEY EVER DARK.

Friend Root:—I notice that F. A. Salisbury, page 895, speaks of having received some of that dark extracted *alfalfa* honey, and you speak of it in your foot-notes in the same way. Now, I wish to say that there *is* no dark extracted alfalfa honey. While it is possible for it to become dark in appearance while in the comb, if left on the hive too long, when extracted, if gathered from alfalfa, it is bound to be white. You might just as well say, "dark white-clover honey." We who are producing alfalfa honey want to get it so understood, that, when we offer alfalfa honey, we mean *white* honey, as it invariably is. There is no danger of real alfalfa honey being called New Orleans molasses. You might call it "partly" alfalfa, or mixed, as it surely is, if dark. Any one acquainted with it would understand what dark alfalfa extracted is, but the majority would not. Charles Adams.

Greeley, Col., Dec. 22.

[Friend A., I think you are right. The pure extracted alfalfa we have had is just as white as any white-clover honey, and just as uniform. The problem seems to be, then, to avoid having the bees gather honey from other sources that may get mixed with it. We conclude this subject with a letter from friend Ball in regard to the honey that showed best on the outside.]

Mr. Root:—I see in Gleanings there has been some complaint about some of the honey you got from me being poor—dark in the middle of the cases, and white outside. Now, Mr. Root, I don't know what to say about this, as you say sometimes. There were a few sections that looked yellow, caused by leaving on the hive too long; and I should have put them by themselves; but I find people sometimes that prefer the yellow cappings to the white. I never could see any difference in the honey. I packed but very little of my honey myself, but I charged the ones who did, to be very careful and not put in any thing that was not nice. Mr. Root, if you have lost by any of my honey, please let me know, and I will try to make it all right. I shall be more careful about assorting and packing my honey after this. W. K. Ball.

Reno, Nev., Dec., 23.

[Many thanks, friend B., for your kind offer. With such a proposition we certainly can have nothing to complain of. I know, as you say, that the stained or yellow sections are just as nice honey, and may be a little better, than the white ones; but there are many retailers who would not accept honey if they found the white sections on the outside and the dark or stained ones inside.]

CLOSE SPACING.

MORE BROOD AND REGULAR COMBS; FIXED DISTANCES.

I wish to add a word on close spacing and fixed distances, as these I regard as very important matters, and they have been my hobby for a number of years. It is folly to use frames hanging hap-hazard, and hand spacing is a sort of guessing at one of the most needed parts of correct bee-keeping. We may space frames ever so nice at the top, but the bottom is sure to be out of true, and a frame can not be made so but it will warp and twist. If there is more weight of honey or brood on one side it will vary the frame ¼ inch. It has long been my belief that we all must come to fixed frames.

You may end up a hive of hanging frames enough to see the bottom-bars below, and you will see them all distances apart (except what are close together).

One cause for so many drones is those wide gaps; and I feel very sure the cause of bare spots of no brood is caused by two combs so close that the queen can not get there. I have seen a fourth of an L. frame without honey or brood, and the cell not more than half depth; and I am very sure that if they had been spaced and fixed at ⅜ apart, there would have been no such trouble. These shallow cells may be caused by being cut off too close; and if a comb is crooked they should be pressed back into place before shaving off for close spacing.

Three years ago I made a number of stays of wood, half the length of, and as wide as the end-bar, and 3/16 thick. These I tacked on to the side of the upper half of the end-bars, which made a nice stay; and as I had used a number of hives with ⅜ spacing, and was so sure it was the best distance, I found those a I could ask. All the now hanging frames can be easily made exact, and it seems to me there should be no stay on the top-bar, as there is no need of it, and it means so much more gum and crushed bees. It is very important that the frames be wedged at each end; that is, on the outside of all, for they all are twisted more or less, and all the little openings will soon be filled with propolis, and nice even spacing is out of the question. In fact, there is need of scraping the edges of the stayed frames once in a while.

You speak of a follower, to be wedged up. To be sure, they have some good features, yet are quite a trouble. If there is much space back of it, if the bees can get there they will, and they are quite apt to find a way there. If a case happens a little out of place, down goes a lot of bees to play the loafer (I know, for I've had the same thing).

If there is a good ⅜ allowed at the outside, and the combs are kept shaved down, or, rather, shaved to start with, and stayed only half way down, there is not much trouble in getting out the first comb. It seems to me not enough to take the place of a follower. I am satisfied there shouldn't be over ⅜ space between combs, and a little less between the bottom of the frames and bottom of the hive; and for losing no bee time there should be only ⅜ at the end of the frames. More space than the little bee can reach across is loss to their valuable time, and just so much to us. Don't you remember, friend R., of cutting out chunks of honey from box hives, and what a narrow passage there was between them—yes, less than ⅜—with the honey sometimes 3 inches thick?

I would say to those who never use fixed distances and ⅜ spacing, just try one hive; and when you get the combs shaved down and all in order, see what sheets of brood you will have, and how the honey will go (upstairs), and, too, where you used ten combs seven or eight will suffice. E. P. Churchill.

Hallowell, Me., Dec. 25.

[You have given us some excellent reasons for close spacing; but ⅜ inch between comb surfaces—isn't that rather close? Why, that is only 1¼ inches from center to center. At the National Association, Dr. A. B. Mason and some one else argued for that spacing, if the spaces were exact. But the majority seem to prefer 1⅜ inch. Your spacers amount virtually to a modified Hoffman frame, or the same as was suggested by J. F. McIntyre. See Gleanings, page 780, last year.]

MIGRATORY BEE-KEEPING.

43 COLONIES GIVE AN AVERAGE OF 47 LBS. PER COLONY IN ONLY 8 DAYS.

Friend Root:—This is a subject that is certainly worthy of the consideration of that portion of our bee-keeping brethren who are not so favorably situated as to reap the benefit of both summer and fall harvest. Situated as I am, on the verge of large areas of land subject to overflow from the Illinois River, thereby rendering it useless for agricultural purposes, and a large per cent of the territory a swampy waste, yet it never fails in the fall of the year to yield up a world of bloom, and hundreds of acres become as yellow as gold, chief among which is the golden coreopsis; and it is here that I have become conscious of the fact that tons and probably hundreds of tons of honey of the very best quality are "lost upon the desert air" for the want of enterprising bee-keepers who will accept of the golden opportunity and place their bees where they will gather and store the precious nectar; and I will just state, that the "golden coreopsis," or Spanish needle, stands at the head of all the honey-producing plants with which I have had any experience. It is not only the richest in nectar, but the quality is *par excellence*, and sells in my home market equal to, if not better, than clover honey. Its weight is fully 12 lbs. to the gallon, and it seems to need little if any curing by the bees when gathered. I have never yet seen any crude or unripe Spanish-needle honey, notwithstanding I have extracted it from the same supers three times in two weeks, and on one occasion twice in five and six days. One colony netted 73 lbs. in 5 days, and the apiary of 43 producing colonies, in 8 day, sproduced 2033 lbs., being upward of 47 lbs. per colony; and this is not true of that particular year only, but it has proven the surest honey-producing plant we have in this locality. Nothing short of cold rainy weather will spoil the harvest from this plant. But to return.

Having occasion to establish out-apiaries I found it impossible to locate them so as to get the benefit of both clover and coreopsis range, and it was no pleasant feature in the trade to see my home apiary outstrip the apiaries isolated from the reach of the coreopsis 2 lbs. to one, if not more, when there were thousands of acres as yellow as gold, and tons of honey going to waste. This seemed to me to be not in keeping with a progressive age; and I reasoned that, could I but successfully move my bees at the close of the clover harvest into the region of the fall-blooming plants, I certainly would add a new impetus to the business, and make the trade more lucrative.

I communicated my ideas to some of my bee-keeping friends, and received cold comfort indeed. "It is a practical impossibility," said one bee-keeper of no light reputation; "and you will be but too glad to give up the undertaking, should your experience be any thing like ours," he further added. Some three or four years have elapsed since this conversation, and I now stand ready to prove that the moving of bees at any time in the year is a practical possibility.

In vindication of the above I will state that I have moved from 100 to 190 colonies from one to eleven miles, twice and three times a year, for the last three years, without the loss of one single colony from the transit. Four years ago I lost 13 of my best colonies, which gave me a pointer that led to my complete success. It is indeed an evil wind that blows no man good, you know; and should your many readers be interested in this subject I may give you my *modus operandi* in a future letter.

Spring, Ill., Dec. 24. J. M. HAMBAUGH.

[Friend H., we are exceedingly obliged to you for the facts you give us above. I have thought of it a good deal since our talk with you on the cars when we were at Keokuk. Your suggestion just now comes like an oasis in the desert, for it indicates that we need not go to Arizona, nor California either, to find undeveloped fields for the apiarist. By all means give us the further particulars.]

A NEW IDEA.

GIVING BEES A FLY IN A WIRE-CLOTH CAGE IN THE WINTER TIME.

Being an apiarian, a subscriber, and a correspondent of the bee-journals, I would suggest that, for the advancement and general progress of bee culture, there ought to be a premium offered of small amount, say $500 or $1000, to any one who would present a new idea upon this subject. You see, I am of quite an inventive turn, and want to be among the "premium-seekers." However, I am very liberal, and I presume I want to "quack" about as bad as some others, and think that I have a new idea, and so for this time I will offer it and not charge a cent. In order to hit upon a new idea, I have always found that we have to look where no other person has already been hunting the ground over. That is the reason why that, when the new idea is first presented, it usually gets so ridiculed, and all the folks think that somebody is going crazy. But as it will not do to ask you to read an *acre* of introduction, I will proceed to offer the new idea, and see how many "knowed it all the time."

Much discussion has been had on wintering, and there are very diversified opinions as to the best way. I conclude (naturally) that *my* way is the best, but as yet I have not seen it advocated. Prepare a room, large enough for your bees; make it very light, also very warm; have it so you can keep it warm with a stove or heater or furnace, as your convenience will best permit. My room is 30x24 feet, and is just above my store, where it keeps quite warm during day and night. When your room is ready you will want my *new idea*—to place at the front entrance of each hive (which will cost about 20 cents to the hive), which allows each colony a space to fly in, of about 10 square feet. In this you can feed them, give them water, and sit near and enjoy them in their flight as long as you please. I tell you, it is delightful. The way to tell whether they are doing well is to notice whether they are dying off faster than those in the cellar. I have 74 colonies in all, some in the cellar; in fact, almost all; but from what I now see, I wish I had almost all in my bee summer-room. I have a cellar 30x40 feet, expressly for my bees, as dry as a powder-house, and probably not surpassed by any in the State; but my summer-room, with the *new idea*, from the present outlook, is decidedly the best, and I feel quite certain that I will adopt it in the future, whether anybody else does or not.

You will very naturally ask whether it is necessary to keep a fire all night. By no means; for if it freezes in the room every night, as long as you have a fire every day it will not hurt the bees at all; neither will it hurt them if it freezes in the cellar, if the cellar is dry; but if it is damp, and it freezes much, you are going to lose your bees. When your bees begin to look shiny with moisture, then look out.

Nirvana, Mich., Dec. 23. F. D. LACY.

[It is just as you say, friend L. The thing you describe is very old. While some colonies have doubtless been saved by giving them a fly in the manner you describe, I believe that all who have used it finally discarded it as being more bother than the bees were worth; and as a rule, the bees that are given a fly in this way for any considerable length of time dwindle down worse than those that are left in the cellar, or outdoors without being meddled with at all. I congratulate you on your pleasant, genial way of presenting the matter; and this, in fact, was the principal reason why your communication on a discarded idea found a place in our columns.]

OUR QUESTION-BOX,

With Replies from our best Authorities on Bees.

QUESTION 175. 1. *At the close of the white-honey harvest, is it better to take off all sections and secure any later surplus by extracting, or would you use sections throughout? 2. What surplus do you have after clover and basswood, and what proportion does it bear to the white honey?*

We have no fall or dark honey here of late years.
New York. C. G. M. DOOLITTLE.

2. Our best crop is clover. We can not give any figures on the relative proportion of both crops.
Illinois. N. W. DADANT & SON.

1. I would take the sections all off at the end of the white-honey crop. 2. We have no surplus after the basswood.
Wisconsin. S. W. E. FRANCE.

1. I should act as my market suggested was wisest. 2. Goldenrod, asters, etc. Often we get as much or more than we got earlier.
Michigan. C. A. J. COOK.

This is a good question to ask, but a hard one to answer. With us it would probably be as well to take them off, as only a small proportion of our surplus is dark.
New York. C. P. H. ELWOOD.

I would use sections to the end of the season. In this locality, when we have plenty of rain, white clover from the seed blooms almost to the close of the season.
Illinois. N. W. C. MRS. L. HARRISON.

I have had very little experience with late surplus honey; but with the experience I have had, I should be in favor of extracting it and feeding it back in the spring.
Ohio. N. W. H. R. BOARDMAN.

1. I think it best to use sections through the season. 2. Helianthus, or wild sunflower, goldenrod, fireweed, and occasionally buckwheat. Usually more than half of my surplus is from these sources.
Ohio. N. W. E. E. HASTY.

1. My practice is to remove all sections at the close of the white-honey flow; though in some localities, where dark honey is plentiful, I presume it is advisable to secure some of it in sections. 2. None worthy of mention.
Vermont. N. W. A. E. MANUM.

1. Having every thing ready for it, I prefer to keep on with the sections, and then the brood-nest is always in good shape. An extracting-super might be better. 2. Not *very* much of any thing, except some years cucumbers and occasionally buckwheat.
Illinois. N. C. C. MILLER.

1. I can sell dark extracted honey to better advantage than dark comb. 2. Sweet clover, bonesets (several varieties), asters, goldenrod—sometimes more than ten to one over white honey, always more. I have had as many as 70 lbs. of sweet-clover honey per colony, and as white as white clover.
Ohio. N. W. A. B. MASON.

All comb honey produced for mercantile purposes should be white, and all dark honey should be extracted. The latter can always be sold, but not so with dark comb honey, which often can not be disposed of at any price, and is of no other value than strained honey. In the southern part of Ohio there is hardly ever more fall honey raised than is necessary for winter stores.
Ohio. S. W. C. F. MUTH.

1. I would not advise raising comb and extracted honey from the same colonies—not in a locality like my own. It is a question of economy of labor. 2. After clover and basswood we have pleurisy-root, buckwheat, goldenrod, and boneset, any and all of which may and usually do give us a surplus crop, and usually we expect to get from one-half to two-thirds the amount of honey from these plants that we do from clover and buckwheat.
Michigan. S. W. JAMES HEDDON.

Here there is usually a fall yield from heartsease, lasting until frost kills the plants, or cold weather keeps the bees in the hives. This is sometimes more abundant than the early honey harvest. The best yield I ever knew came in the fall. I prefer to "taper off" by giving extracting combs to as many colonies as possible, so as to reduce the number of unfinished sections to the minimum.
Illinois. N. C. J. A. GREEN.

1. This is a question for the comb-honey man to answer; but it occurs to me, that, if rigged up for comb honey, I should prefer to run the entire season in that line rather than be at the expense and bother of providing myself with the two outfits. 2. Fall flowers, and occasionally mint and buckwheat; probably the proportion would be one-fourth as much as compared with white honey.
Wisconsin. S. W. S. I. FREEBORN.

I always take off sections of white honey before the advent of dark honey, for a very thin border of dark honey in a section spoils the whole for sale as a No. 1 grade. If my fall yield was usually large I would run for comb honey until the close of the season. In my locality I have a trace of buckwheat, but in a favorable season I have a bountiful yield of "bug-juice" for a series of years. Probably fall honey is five per cent of the whole yield.
New York. E. RAMBLER.

[As I expected, most of the friends say, "Let the bees finish up what surplus they are going to give, in the sections." Friend Heddon suggests, however, that it is a question of economy in labor; and Rambler breaks over our rules, and speaks of "bug-juice," when it was agreed, as I had supposed, that no one was ever to use the disagreeable words any more. But when the brethren were talking about taking their chances of having their white honey spoiled by a streak of dark all around the outside, I began to wonder whether a good many of them had not forgotten the dark, disagreeable *honey-dew* that pestered us so, only five or six years ago. For my part, whenever I find this dark, cheap, molasses-looking stuff dotting the combs all through the hives, I would pull off the sections of white honey as fast as possible, even if some of them were not more than half filled. Friend Muth hits it exactly when he says that dark comb honey oftentimes can not be disposed of at any price. We have got a good lot on our hands now; and if there is anybody who wants to make us an offer he can have it very cheap.]

SPECIAL DEPARTMENT FOR A. I. ROOT, AND HIS FRIENDS WHO LOVE TO RAISE CROPS.

A PLEA FOR OUR SEEDSMEN, AND OUR CATALOGUES AS THEY ARE; BY ONE WHO HAS HAD YEARS OF EXPERIENCE IN MARKET-GARDEN SEED-STORES.

Friend Root: — Having been a reader of GLEANINGS for several years, I, of course, take some interest in its make-up, and particularly so in regard to cutting down the varieties in seed catalogues; but at the same time I can not indorse all you and Mr. Green say on that subject. While I agree with you, that we have too many kinds, yet the seedsman has points to look after that Mr. Green loses sight of entirely. From his standpoint he would have nothing in a seed catalogue except the kinds he had tested and found to be the best—losing sight of the fact that a seed establishment is not a local concern. It is national. Catalogues are going from Maine to California, and all the isles of the sea. Now, while the kinds he would catalogue may be the best for his particular locality, how is it with his neighbor in California? The climate there is very different; the varieties that do best here may be and often are entirely worthless there, while the very kinds Mr. Green condemns will be just what he must have to make a success. The seedsman is constantly getting reports from his customers from different parts of the country, and knows this to be a fact; and as long as he has the financial end of this problem to handle, it is safe to say that he knows what he is doing. Now, if the seed establishment is to be a *national* concern, the seedsman must carry varieties adapted to all parts of the country; but if he is just going to keep a country store, the case is very different. Which is it to be—shall we adopt Mr. Green's policy, and thereby reduce all the big seed establishments down to the same footing with the country store, or shall we consider that seedsmen know their business, and conclude to let them run it as their experience has taught them is best? I believe there is not a seedsman in the world who would not gladly cut very materially, if he could do so, and satisfy his customers.

Suppose we come right down to the local aspect of the case—the local market. If Mr. G. had followed gardening and attending market for a living for, say, ten years, as I have done, he would begin to talk like this, perhaps: "Yes, in *theory* it's all right; but as a *bread-winner* it is not a success." The man who attempts to make a living on marketing very soon discovers that there are different tastes to consult besides his own; and a customer who wants a head lettuce, for instance, will have a head lettuce, if it's on the market, while probably the very next customer would not have that kind if you *gave* it to him. You may rest assured, the market-gardener knows better than to cut down his list to the extent Mr. Green recommends; and if his seedsman doesn't keep the seeds he has found to be the most profitable, he will send to some other part of the country and get them. It is not theory the market-gardener is after; it's hard, solid facts in the shape of dollars and cents; and he knows what brings them in, better than any outsider can tell him.

One more point and I will close; but in that one point I beg leave to differ with Mr. Green, from the word go. He says, in GLEANINGS of Oct. 15, "The new kinds and sorts are mostly made by the seedsman in order to have a novelty to introduce." Shades of Moses! Did he ever stop to consider how long it takes a seedsman to get up a reputation, and that the reputation represents just that much capital? The better it is, the more it is worth. It certainly takes more than *two years.* Now, I ask you in all candor, Do you think that, after a seedsman has gotten up a pretty good reputation, he is going to be either knave or fool enough to throw it away for the few paltry dollars he would get out of it as a novelty? Oh, no! it's worth *too much money* for that, even if he were inclined to be dishonest, and I believe very few are. I think if Mr. Green had, say, two years' experience now in some good reputable seed-house it would modify his views considerably as to the honesty of seedsmen, and also as to the cutting-down process. Study this question over on both sides, friend Root, before you make up your catalogue; and I think that, if you expect to run any thing more than a local store you will not cut down so severely.

Yours respectfully, ——.

My good friend, I am very glad indeed to get the above communication, especially because it enjoins the very virtue (charity) that I have been exhorting to. I am glad to have somebody speak well of the seedsman, who is in no way interested, and yet one who knows all about the inside machinery of the establishment of a seedsman who issues a nice catalogue. But, my good friend, your experience has been mostly with one of the best and most honorable seedhouses in the United States. Our Experiment Station, represented by our good friend Green, knows very well that all you say is true of the seeds where you work. If you take all the seed catalogues that are put out, as friend Green and I have done, you will see a good deal that sadly needs the very work that friend Green and myself are trying to do. The same thing is over and over again catalogued under different names; and no attempt is made, seemingly, to reduce the number. Many times there is only a *shade* of difference in varieties, and yet year after year the two are catalogued. Again, there is the greatest misrepresentation. Let me give you an illustration. It will come in very well, for I have been thinking to-day it devolved on the bee-papers to show up *again* this fraud in regard to the Rocky Mountain bee-plant; viz., calling it by a new and flashy name; representing it as heretofore unknown, and telling most *preposterous* falsehoods in regard to the amount of honey it yields. We exposed it a year or two ago, and I wrote to the proprietor of the seed catalogue. It is true, I got a reply from him, but he neither seemed to want to be set right nor did he make any promise of correcting his false statements when they were plainly pointed out to him.

A TRIBUTE TO "WHAT TO DO AND HOW TO BE HAPPY WHILE DOING IT."

I send you $1.00 for your excellent GLEANINGS. It is as good as the Bible in many respects. I can just cry with joy over a great part of your talk, of the garden as well as the Home talk. From experience I know just how dear Mother Earth fills you with joy and wonder. Oh how wonderful those berries are! I had a crop last year that surprised the people about here, and also with my early and late work in the garden. God smiles over me with love when in the field. I always feel like shouting when I see the way *you* get at it, which is the true way to be happy. May you live long to encourage all.

Hallowell, Me., Dec. 25. E. P. CHURCHILL.

Why, bless your heart, dear brother, I did not know before that the world contained *another* man who loves God and nature so exactly as I do. And then your wonderfully graphic way of telling it—"*God smiles over me in love!*" There is inspiration in the very thought. If I ever get away down in Maine, won't we have a visit?

A KIND REPORT FOR GLEANINGS, AND A GOOD REPORT FROM WASHINGTON.

I can't do without Gleanings. Why, do you know the Dec. 1st issue was worth to me more than ten years' subscription? I have had celery on the brain for the last year. We have sold over $1000 worth so far this season, and find ourselves with 12,000 plants on hand, and no place to store it, when here comes Gleanings and tells us to take the pigpen. Good for you! We have just got the pigpen, 30x25 feet; but who but A. I. Root would have thought to make use of it? The boys are at it now. The floor came handy to line the sides with, leaving a 6-inch space all around, which we fill with earth from ground underneath; and now with three or four loads of manure on top of the roof, we are fixed with a celery-house that will hold at least 6000. Celery here in our moist cool climate grows wonderfully large and fine. We have thousands that will weigh 4 or 5 lbs. to the single stalk—Golden Self-bleaching, 2½ feet tall, with leaves that are two inches at the base, and as brittle as an icicle.

Fidalgo, Wash., Dec. 12. H. A. March.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

OBJECTIONS TO THE 60-LB. SQUARE CANS, FROM A HONEY-DEALER.

I notice considerable discussion in Gleanings about the 60-lb. tin cans for extracted honey. My observations are, that they are not the best, for they are very tender, and easily made to leak, especially if out of the cases, and nails are so apt to be driven into the tin through the cases. They are too frail, and not solid enough for the weight put in them. When they are leaky it is difficult to tell where the leak is, and you can not stop it without the tinsmith. The pine fish-kegs holding 75 and 150 lbs. each are the cheapest and most sensible packages for extracted honey; for, if leaky, the hoops can be driven and quickly coopered. Another objectionable feature of the tins is, that buyers get the impression that all honey in those cans is California honey, and are more or less prejudiced. What say other honey-dealers?

Albany, N. Y., Dec. 25. H. R. Wright.

[We should be glad to hear from the other dealers.]

THICK AND THIN TOP-BARS.—ONE WHO HAS USED AND DISCARDED CLOSED-END FRAMES.

The new catalogue is at hand. It is a very neat one, and quite an improvement over former editions. I have used top-bars varying from ¼ inch to 1 inch in depth, and from ¾ inch to 1⅛ inches wide; but I have always had more or less burr-combs after the second season. I have some of Root's S. frames that have been in use two seasons, and have never had burr-combs built above them, though I have had sections filled over them each season; but, judging from experience, I am sure that burr-combs will come, in time. Exact spacing, by using fixed distances, can be maintained only by having every comb perfectly straight, and the septum exactly in the center of the frame; in fact, each comb must be perfect and an exact counterpart of all the others; if not, you will very likely change the spacing every time you change a frame. Fixed distances have advantages for those who move their bees often. They also have disadvantages; and the point for each one to decide is, whether the advantages will outweigh the disadvantages. I used two thousand closed-end frames two seasons, and have decided in favor of hanging-frames.

Robert E. Ashcraft.

Brookside, Mich., Dec. 8.

[That's right; let's have both sides of the question. You do not tell us what sort of bee-space you had when you made your experiments with top-bars. In Elwood's apiaries I saw no burr-combs, or almost none, and he used a ¼-inch bee-space, scant if any thing. The same condition of things I saw in other apiaries where the ¼-inch bee-space and fixed distances were in use. There are several things that go to prevent brace-combs; and not the least important is the *right bee-space* above the frames. I am glad you have spoken out in regard to closed-end frames. There are and will be others like you; and, on the other hand, there are just as many who would use nothing else. It's a good deal in knowing how to handle them. We can't (no, we won't) all use the same kind of frames or hives.] E. R.

WHAT THE EDITOR OF THE TELLER SAYS OF OUR REPRODUCTION OF THE FRANCE BEE-KEEPERS' ASSOCIATION.

Mr. Root:—I notice with pleasure your reproduction of the assembly of bee-keepers recently at Platteville. You could hardly have been prompted to the undertaking by that spirit which usually goes under the head of "enterprise," for there surely is no money in it. The *Root* of your motive must be in your "good will toward men"—a virtue that blossoms profusely in Gleanings. The faces of the group are nearly all familiar to me. They are of worthy citizens who are mostly friends and patrons of *The Teller*. Edward Pollock.

Lancaster, Wis., Dec. 20.

A LITTLE MORE ABOUT THAT "SNUFF-BOX," ETC.

Friend Root:—I think your "snuff-box" illustration on page 757, in connection with those delicious gems, was very unfortunate, as one does not like to be reminded of the filthy thing every morning at the breakfast-table. Why did you not think of the humble clam, or the more æsthetic oyster whose bivalved shell opens like your "hinged gems"? In the South your illustration would not be appropriate, as the snuff-box in common use among the "ladies" at home, in company, and at church, is the ordinary small tin can in which it is packed for sale. The cover is removed, and the can passed around for each who desires, old and young, to "dip" in their little "tooth-brush" (a small stick chewed at one end), with which the snuff is "rubbed" upon the teeth. It is certainly an evil habit, injurious to both body and mind, if not degrading to the soul. I often think, in connection with the tobacco habit, to which I was at one time addicted, of that terrible sentence, "He that is filthy, let him be filthy still."

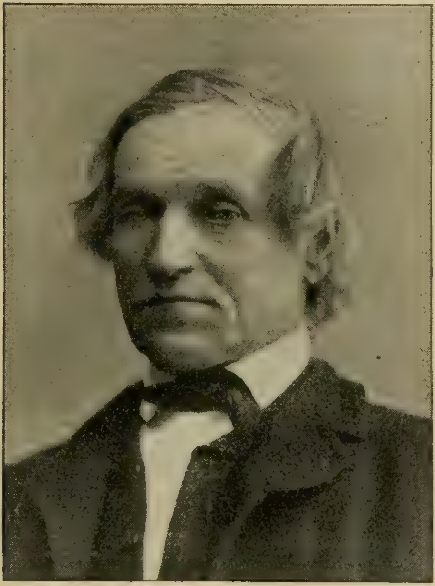
Some one, long since, asked in Gleanings, whether a person could be a "consistent professor of religion and be a user of tobacco." I should say yes; for a "professor of religion" covers a broad ground, and not well defined. But if the question were asked, "Can a person be a *Christian* and a habitual user of tobacco?" I should say no. A *Christian* will strive to overcome all evil habits. C. F. Parker.

Mentone, Ala., Dec. 21.

OUR HOMES.

I therefore, the prisoner of the Lord, I beseech you that ye walk worthy of the vocation wherewith ye are called, with all lowliness and meekness, with longsuffering, forbearing one another in love; endeavoring to keep the unity of the Spirit in the bonds of peace.—EPH. 4:1–3.

This is a wonderfully interesting world to me. I love the plants and the flowers; I love the moon and the stars, especially when the plants and the flowers are held in their icy bondage. During these shortest days, there is a wonderful interest to me in marking the course of the shadow, especially as it approaches noontime, and comes to its highest point northward. As the sun slowly comes to its furthest passage in its journey south, and rests awhile, apparently, just before Christmas, then gradually starts northward to bring us a new spring and a new summer, and a new year, it becomes to me a matter of intense interest. I love, also, to see the sun rise and set—to see how it hitches a little further every day northward, and thereby gives us days a minute or two longer. But amid all the studies of the things I see, nothing interests me more than the study of humanity. I especially love to meet with people having peculiar attainments, graces, or individualities. In my recent visit to Keokuk I met many friends I had never seen before. One of them interested me so much that I have asked for his picture. He has granted me permission, but it was only when I explained to him why I wanted it, and I take pleasure in introducing to you my good friend Wyand, of whom I have previously spoken.



HENRY WYAND, KEOKUK, IA.

Those who have seen friend W., and talked with him, will agree that the picture is a very faithful one, but still it does not show the peculiar vein of pleasantry that he shows when talking; in fact, I feared we should never get that in any picture unless the artist should take him unawares by the instantaneous process. I am not going to give friend Wyand's biography, because I have not got it to give. He is quite a modest man, and says that he does not think he would have granted my request had it not been "for the outside pressure in the family." It was friend Wyand, you may remember, who captured Ernest and myself and several others by promising to show us artesian wells, their attendant water-motors, dynamo, etc. I judge he is a man full of life and energy; and one thing that interested me in him was that he is, like myself, very much inclined to be impatient when things do not move off in harmony with his stirring nature and disposition. I should not wonder if his wife and children would smile a little when they read this. He is not only a rapid walker, but he is a rapid talker as well; and if you are not close by him, and listening attentively, you may not catch all he has to say, for he is full of ideas and projects, and especially full of quaint dry jokes that surprise one and get him to laughing until he gets in a mood of being pleased at any thing that may be said. As I was to leave on the 3-o'clock train of the last day, in order to make home before Sunday, I, with several others, made my visit to the Dadants the day before. Then when the convention adjourned to go in a body to the Dadants', during the last afternoon, it was arranged that I should go with friend Wyand to see the greenhouses, strawberry-patches, zoological gardens, etc. At the adjournment of the convention, the various vehicles drew up and rapidly loaded up the members. Friend W. was on hand promptly, according to appointment; but his horse and buggy, for some reason, had not "materialized." My good friend began to be greatly annoyed, because every minute shortened the time we should have for visiting the various places that he knew would interest me. He had planned a pretty good-sized program for only two or three hours, and it was very desirable that we get to moving. One of his daughters, so he told me, was to bring the horse and buggy. Ten, fifteen, twenty minutes passed—no daughter came in sight. He went up and down the sidewalk with manifest impatience, and would insist on going to the livery for a rig; but I urged him to be patient, and also assured him there was some excellent reason for the unexplainable delay. While we were waiting I made the acquaintance of another daughter of his who is head saleswoman in a fine drygoods store near by. It always pleases me to be able to take an expert business woman by the hand. The proprietors had tried repeatedly to get a man to take charge of their store. Miss Wyand, however, seems to sell more goods, and to please customers better, than any of the male clerks that can be found around Keokuk.

Finally the missing vehicle, with its nice-looking young lady driver, makes its appearance. Now, it was a very easy thing for me, under the circumstances, to see that my good friend ought not to scold in the presence of company. At the same time, I was well aware that, under the same circumstances, *I* should have been very likely to scold, even in the presence of company. May God forgive me, and may my good patient friends and relatives forgive me, for the many times I *have* forgotten, neglected, or refused, to follow the same course which I am trying to teach you, dear friends, as I talk to you this morning. I knew that friend W. felt a good deal like scolding, and I was afraid he would scold before he gave his good daughter time to explain. The reason I was afraid of it is because it would probably have been just like *myself* to do such a thing. As she drove up, looking bright, ruddy, and happy from her exercise in the cool autumn air, she presented a very pretty picture. Very likely she has read GLEANINGS and these Home papers. She knew that the man by her father's side was A. I. Root; and if my good friend W. had made up his mind that he would scold her for being late, I was equally determined that he should *not* scold a word, if I could stop it. I am not naturally inclined to push myself forward among strangers. It is not at all easy for me, in one sense, and I am afraid it never will be; yet when I can push forward for Christ's sake, I hope I am ready and glad to do it. Yes. I can look back to many times when I have really enjoyed being seemingly rude, for the time being, when I did it for *Christ Jesus'* sake.

Friend Wyand started, in his rapid way, to the buggy as it rounded up to the curbstone. But I can walk fast too, and I pushed ahead of him, introduced myself to his daughter before he had time to say a word, and talked so fast, at the same time taking pains to stand between the two, that he could not even get a word in "edgewise." Perhaps he did not notice it at all. May be he thought it a little strange that I did not wait to be introduced in the orthodox way. But I hope that, when he sees this, he will forgive me. Yes, I am quite sure he is glad now that I did just as I did; and I am sure, too, that my good young friend will forgive me. I am inclined to think that friend Wyand's family, all of them, girls and boys, are in the habit of working outdoors and indoors. I had decided, in my own mind, that Miss Wyand was quite a pretty young woman; but as I finally gave her father a chance to speak he ventured just a little word of remonstrance, asking her why she did not get there sooner. My talk with his daughter had disarmed him, and he had doubtless got over most of the impatience he felt, and under the circumstances he did exceedingly well. I have not a word of fault to find with him, mind you, for he did a good deal better than I should have done, I fear. There *was*, however, a faint shade of fault-finding in his tone, and it brought a beautiful rosy spot on either cheek as his daughter replied:

"Why, father, I hurried the boys up all I possibly could, but I really could not *make* them bring the horse up any quicker, and I drove just as fast as ever the horse could go."

She glanced at me as she said this, feeling the same kind of pain, no doubt, that you or I would if you, my friend, were found fault with when you are first introduced, say, to the editor of one of your family papers. We soon learned that Mr. W. owned a horse that was in the habit of making the gravel fly, much after the disposition of its owner. We held our hats, and clung to the buggy-seat for fear of being bounced out; and when we stopped to look at interesting things the horse had a habit of starting without orders, as horses belonging to quick, nervous people, often do have. In fact, while in the zoological garden, one of our good bee-friends was knocked down and run over—only by the light buggy-wheel, however, just on account of this peculiarity. Let me digress enough to urge you not to permit horses to get into this habit of starting until bidden. It will pay you in dollars and cents to teach your horse not to move until you draw up on the reins, and tell him to go. Not only has money been lost, but also valuable lives as well, in this very way. You can teach the most spirited horse you own to stand until you tell him to go, if you will only take the pains, and you will save time by it in the end.

Friend Wyand's wonderful flow of pleasantry and good nature was somewhat checked by being late in starting. There, again, he is just like myself. A little thing of this kind will upset me for an hour or two unless I make a great effort to overcome it. At such times I need to say over and over again my little prayer, "Lord, help!" He took us first down to the wonderful Government Canal, a structure that cost over two millions of dollars, made on purpose to permit boats to go by the rapids on the Mississippi River. It has the usual arrangement of locks, like ordinary canals, but on a much grander scale. Steam-engines are employed to work the locks, and the machinery is of the most beautiful kind. I was not only greatly astonished but much amused to see friend Wyand address the Government officers as if they were men in his employ. In fact, I rather expected to see some of them resent his familiarity; but one of his comical smiles, after he had given one of his peremptory commands, made it all straight, and they went through all the operations, and explained every thing to me in a way that made me feel still as if I were at home, and among my neighbors. The Government Dry-docks were a wonderful thing to me—a place where they brought in great steamboats, and then let the water off so the carpenters could do necessary repairing. A little further on, we saw some beautiful rows of strawberries, and a man at work near them. Friend Wyand made this man stop his work on the other side of a field, and answer questions about the strawberries, at the top of his voice. Then we pulled around to friend W.'s home. He evidently had looked forward with pleasure to introducing your humble servant to the different members of his family; but he was somewhat vexed again to find not a soul at home. It was a beautiful day for outdoor work, and every one of them was busy somewhere. His whole premises on the top of the hill showed industry and hard work. He loves bees, fruit, and flowers as well as the rest of us. Pretty soon we stopped in front of a good-sized greenhouse. He made himself at home here too, and bossed the people around as if they were all working for him, just as he did before. I was greatly delighted to find a house heated entirely by overhead steam-pipes. The person in charge was a pleasant-faced woman, and I could have spent an hour in talking with her about plants, soil, new methods of heating, etc. She said they had recently taken out the pipes under the beds, and had placed them overhead, and were much pleased with the result.

Friend W. has taught me a useful lesson, and it is this: That one may go about among friends and neighbors, among business men and people, even among officers of the government, and may make them do every thing he asks, providing he has grace enough in his heart to keep up a vein of pleasantry and good nature to disarm all unpleasant feeling. This man captivates and makes friends by a sort of droll way. Perhaps he has cultivated it, and perhaps it is a gift of God largely—a gift that many of us might have, certainly, in a much larger degree if we would only strive hard for it—a faculty of seeing something pleasant, perhaps I might say in *every* thing, in all the duties of every-day life. It was on this account I was a little glad to see him tried by the delay of his horse and buggy. I did not want him to have trouble, but I wanted to see how far his native grace would bear him out in the hour of trial. I do not know whether he ever lets his temper come out, and scolds like fun, or not. I am sorry to say, that, with the amount of business we had on hand when I was there—that is, one kind of business, I did not find out whether he was a Christian or not. It may be I asked him the question—I hope I did; but if I did, I have forgotten what he said. It has occurred to me since, though, that this good friend of mine would have a wonderful power in bringing souls to Christ Jesus if this special gift of his were enlisted in the cause, and if his quaint smile and vein of pleasantry could all be laid *at the foot of the Master*. When I see a man with this gift I often wonder how he will "stand fire." When Satan brings all his artillery to bear, how long will he stand unflinching, and without being demoralized? Dr. Miller has a wonderful gift in this line. I asked him a few days ago whether he could go into business, real hard work, and keep that steady good nature constantly about him. I wanted to know how big a reserve he held back for cases of emergency. Mrs. Root has a great mania for large cisterns. When the masons and others ask her what in the world she wants a cistern *so big* for, she says she not only wants one that will hold water enough for *our* use during a dry time, but one that will bear drawing on for the neighbors. She says she never wants to tell a neighbor that they can't have all the *water* they have a mind to come after. Now, friends, it is not the cistern water *I* need, but it is grace from on high. I want a great big lot of grace—not only enough to keep A. I. Root going, but enough to give the neighbors all around—enough to give the children at home. Yes, if my good wife should ever be worn out by many cares, so that she needs a little help in that line, I am earnestly praying that God may give me this reserve force of grace to help her. Nay, further: May God give me grace in such unstinted supply that I can pour it out to you, dear readers, and not be impoverished. And what is it we want finally but the gift of the Holy Spirit? And have we not the promise? And this brings us to that verse I have loved to read over and over again:

> If ye, then, being evil, know how to give good gifts unto your children, how much more shall your heavenly Father give the Holy Spirit to them that ask him?

I wish to refer again to this matter of scolding before folks. Your children need exhorting; and they often need, perhaps, a severe reprimand; but do not do it on the impulse of the moment; do not do it from impulse at all. Do it from cool, steady principle, from a sense of duty. Only yesterday a man was slicing off wooden separators. One boy picked them from the machine, and laid them in piles of 25 each. Two more boys took these packages of 25 in long baskets to the dry-house, and piled them up with sticks between them, so they would dry out smooth and straight. The boys who were carrying them to the dry-house got a little ahead of the slicing. While they were waiting for a basketful they amused themselves by throwing splinters and spoiled separators on the large driving-belt. It was funny to see them whip around the pulley. The man who ran the machine was called away for a few minutes; and when he got back, some of these refuse pieces of wood were in the gearing, or large iron cog-wheels, throwing the belt off, and springing the main shaft. The boys said they were cleaning off the machine, and a handful of splinters fell into the gearing. They had been instructed, before going to work near the machine, in regard to the danger of being around such machinery, and had been cautioned to be very careful. They were certainly very much out of place in even throwing shavings on the belt—still more in cleaning off the chips and shavings while it was in motion. I reprimanded them pretty severely, but I did not feel quite satisfied that the whole truth had come out. The next morning, the smallest of the three boys came to me, saying that his conscience troubled him, and confessing that he not only put pieces on the belt, but he also put some in the heavy cog-wheels, to see it "chaw them up." This, you see, threw considerable additional light on the matter. Had I yielded to impulse I should have made the boys pay all damage caused by getting the machine started again. It seemed pretty hard, however, to ask the one who so frankly confessed his fault to do this. I decided to let the whole matter rest until I could see each one of the boys alone. I am now very, very glad that I did so. I am glad that, when I had time to think the matter over, I could see very clearly that the loss of time and money was but a small matter compared with the falsehood that seemed connected with it. I have been anxious to bring these boys to Jesus Christ; and after I had waited half a day I could keep this thought in mind far better than if I had spoken about it when I was provoked. I do not know even yet just where the truth does lie—that is, it is not very clear whether the shavings ran from the belt into the gearing, whether they dropped from the machine into the gearing, or whether some one of the boys put in so large a handful as to stop the machinery with a sudden shock, and spring the shaft. Many of you will doubtless say, "Mr. Root, I would not have such boys *anywhere on the premises*." Gently, gently, dear friend. I have tried boys by the hundreds, and these boys will certainly average as well as any of them. It is boy nature to try experiments, and have fun, especially when he has to wait for something. If I should turn them off and try others, I should have to go through the same experience in teaching others; and these boys have been with me for some time, and are getting pretty well taught. I don't think they will play with dangerous machinery any more.

Some years ago, when I had a store on the street up town, I came home from prayer-meeting and found several customers in the store, and nobody there to wait on them. The two clerks whose business it was to take charge had each left, presuming the other was there. One of them was a professor of religion, and the other was becoming quite a young skeptic. He claimed that church-members and professing Christians do not do any better—perhaps not quite as well—as those who make no profession. I was anxious that he should have plenty of proof to the contrary. But I was so vexed to find the clerks so indifferent to the plain demands of business, especially in the middle of Saturday afternoon, that I scolded—well, more than I knew, till I came to think it over afterward. It was the young skeptic I found first. He took it very meekly, and did not offer a word of apology; and when I afterward begged his pardon he said he did not try to make any explanation then, because he thought it would be better to keep perfectly still until I had "cooled off." I presume there was wisdom in what he said. He, a non-professor, showed more wisdom than his employer, who had just returned from *prayer-meeting*, and who did a good deal of exhorting. Whenever I see him or think of him, a feeling comes up, "Oh that I could have those few minutes back again to do over!" He accepted my apology, and said it was all right, and that, under the circumstances, he thought very likely I was excusable. But my conscience did not tell me so. He is not a Christian yet, and something seems to say to me that my words during those five or ten minutes may possibly stand in the way of his ever becoming one. I do not know whether he has ever told his relatives about it or not. They are very kind, good friends of mine. Very likely he had manliness enough never to repeat to anybody what I did say to him. Perhaps you say I am too sensitive—that a clerk who deserted his post at such a time *ought* to be severely overhauled. Dear friend, nobody has ever censured me for that act. It is only the *still small* *voice* that bids me let *reason* rule, and *not* impulse; that bids us all, in the language of our text, be "worthy of the vocation wherewith we are called, with all lowliness and meekness, with longsuffering, forbearing one another in love." The last caps the climax of it all. When you feel it is your duty to reprove, rebuke, or remonstrate, let me beg of you to do it in these words—"Forbearing one another in love."

Now may God's Holy Spirit help you, as it is helping me, to be slow, and to wait until you can use just the words, just the manner, and in just the *place*, that will count strongest for Christ Jesus.

CONVENTION NOTICES.

The annual meeting of the Ontario Bee-keepers' Association will be held in the city of St. Catharines Jan. 7 and 8, 1891. All interested are invited W. COUSE, Sec., Streetsville, Ont.

The Vermont Bee-keepers' Association will hold their annual meeting in the parlors of the Addison House, Middlebury, Vt., Jan. 28, 1891. J. H. LARRABEE, Sec'y.
Larrabee's Point, Vt.

The 8th semi-annual meeting of the Susquehanna County Bee-keepers' Association will be held at Montrose, Pa., Thursday, May 7, 1891. H. M SEELEY, Sec'y.
Harford, Pa.

The annual meeting of the Indiana State Bee-keepers' Association will be held in the Agricultural Rooms, State-house, Indianapolis, Jan. 16 and 17, 1891. G. C. THOMPSON, Sec'y.
Southport, Ind.

The annual meeting of the Ohio State Bee-keepers' Association will be held in Toledo, Ohio, on Tuesday and Wednesday, Feb. 10 and 11, 1891. Full particulars as to railroad and hotel rates, and place of meeting, will be given later. Let all interested in bee-keeping make an extra effort to be present.
Bedford, O. MISS DEMA BENNETT, Sec'y.

The Nebraska State Bee-keepers' Association will hold its annual convention in Nebraska Hall, State University, Lincoln, Jan. 13—15, 1891. Take a receipt from your home agent, and have it read, "To attend horticultural association," which meets at the same time, and this will entitle you to a return ticket at one-third fare. J. N. HEATER, Sec'y.
Columbus, Neb.

The 22d annual meeting of the New York State Bee-keepers' Association will be held in Agricultural Hall, Albany, N. Y., Jan. 22—24, 1891. Reduced railroad rates. Pay full fare to Albany, and we will give you a return certificate over any road coming into Albany (except the Boston & Albany) at one-third the regular fare. A cordial invitation is extended to all. Come, and bring your friends with you. A complete program will be published as soon as completed.
G. H. KNICKERBOCKER, Sec'y.

The Eastern Iowa Bee keepers' Association will meet Feb. 11 and 12, 1891, in Maquoketa, Iowa, at the Dobson Town-clock Building, to commence punctually at 10 A.M. There will be a large turn-out of the prominent bee-keepers of the State. There will be a question-box, free to all, in which any question that you wish discussed can be presented and answered. Let all be on hand, and bring in your report for 1890, spring count, or from May 1. The people of Maquoketa kindly furnish us a free hall. FRANK COVERDALE, Sec.

PRICE LISTS RECEIVED.

J. G. Kundinger, Kilmanagh, Mich., sends us his 24-page list of apiarian supplies.

C. P. Bish, Grove City, Pa., has published his annual catalogue of bee-keepers' supplies.

We have printed for Jenkins & Parker, Wetumpka, Ala., a 60-page list of every thing pertaining to apiculture.

A COMPLIMENTARY NOTICE OF GLEANINGS.

THE editor of the *American Bee Journal* gives us the following very kind notice in his journal, page 820:

> We congratulate Brother Root upon the fact that GLEANINGS has reached, and even passed, the ten thousand circulation, which it set out to do some months ago. GLEANINGS richly deserves this mark of public favor, for it is beautifully printed and carefully edited. If the reader desires to take another bee-periodical besides the *American Bee Journal*, we shall be pleased to send it and GLEANINGS for $1.75 a year, or both these and the *Illustrated Home Journal* for $2.15. This is a rare opportunity to secure three good periodicals for about the regular price of two.

As we have before stated, we make the same club rates—that is, the *American Bee Journal* and GLEANINGS for $1.75, or both and the *Illustrated Home Journal* for $2.15.

EDITORIAL.

The discretion of a man deferreth his anger; and it is his glory to pass over a transgression — PROV. 19: 11.

STRAY STRAWS is no longer an experiment. "It takes," and we're going to make it lead off.

THE NEBRASKA BEE-KEEPER.

THIS is the title of a new bee-journal, edited and published by Stilson & Sons, York, Neb. It is issued monthly, and contains 12 pages and a cover. Its general appearance and make-up are good. The price is 50 cents per annum.

THE MICHIGAN BEE-KEEPERS' ASSOCIATION.

BY some inexcusable oversight on our part, we omitted to give notice of the State convention, to be held in Detroit, January 1 and 2. This notice will hardly be in time to be of any use; but its non-appearance can not be attributed to the secretary, Mr. Geo. E. Hilton. The senior editor will be present.

THE BEE-KEEPERS' REVIEW.

THE December issue of that sprightly monthly is now on our table. It is enlarged to 28 pages, with a tinted cover. The price is $1.00 per annum. The frontispiece, or the design on the cover, is superb, and Mr. Hutchinson is to be congratulated upon the fine appearance of his paper as well as the general excellence of its subject-matter.

MORE ROOM.

WE find that the demands upon our space are excessive; and for the present, at least, we have decided to make all answers or "foot-notes," as they are called, and editorials, solid, like the correspondence. This will give us over one whole extra page every issue, or one whole extra issue during the year. For distinction, foot-notes will always be put inside of brackets.

LIFE-MEMBERSHIP IN THE N. A. B. K. A.

BRO. NEWMAN, of the *American Bee Journal*, says that it is ten years since he paid the fee of $10.00 for life-membership in the N. A. B. K. A., and he says: "We already have our money back in annual fees for the $10.00." The following is the present revised list.

D. A. Jones, Beeton, Ont.
Thomas G. Newman, Chicago, Ill.
A. I. Root, Medina, O.
E. R. Root, Medina, O.
J. T. Calvert, Medina, O.
Charles Dadant, Hamilton, Ill.
C. P. Dadant, Hamilton, Ill.
Eugene Secor, Forest City, Ia.
Dr. C. C. Miller, Marengo, Ill.
O. R. Coe, Windham, N. Y.

Remember that, after becoming a life-member, you are not necessarily obliged to attend the meetings; but you do thereby give the society a big leverage for the accomplishment of much good to bee-keepers.

CASH COMMISSION TO LOCAL AGENTS.

To any one who will take the trouble to canvass his neighborhood, and call the attention of bee-men, by *personal interview*, to the merits of our journal, we will allow a cash commission of 25 cts., providing that all names so obtained are taken for not less than $1.00, and that he does not advertise for less than that price. No one can be agent unless he can send in at least one name besides his own; in this case, $1.50 pays for the two names. At least *one-half* of the names must be new.

THE COMBINATION HIVE.

A NEW bee-journal, under the caption of *The Queen Bee*, is just out. It is edited by E. L. Pratt, Beverly, Mass. In the editorial leader the Combination hive is described as simply the Dovetailed hive with an outside winter-protecting shell, or Alley winter case. Bro. Pratt speaks very highly of both, and the two he calls the Combination hive. He says: "We are all aware that the New Dovetailed hive is a well-made, cheap, and excellent hive, but is not adapted to wintering out of doors in cold climates. We have adapted the Alley case to this hive, and can guarantee them perfect winterers when arranged in this manner."

MEDALS OF AWARD.

There has been, for a couple of years back, a provision in the constitution, entitling affiliated societies in the North American Bee-keepers' Association certain privileges, among which was, that said societies shall be entitled to the services of a judge to award premiums at bee and honey shows, and that they shall also be entitled to receive two silver medals, to be offered as prizes, open for competition to all their members. So far, the national organization has conferred neither of these privileges. While on the sleeper, *en route* for Chicago, just as we left Keokuk, this matter was brought up by Mr. R. McKnight. One of the executive committee of the society was present, and a couple of the ex-presidents—Mr. T. G. Newman and Dr. C. C. Miller. We all admitted this matter had been overlooked so far, and that something ought to be done. After consultation, the executive-committee man present (E. R. Root) agreed to bring the matter before the other officers, and the same is now under consideration for more definite action for the future.

IS THE USE OF FOUNDATION PROFITABLE TO THE BEE-KEEPER?

ON page 213 of the *Bee-keepers' Review* for Dec. 10, friend Hasty uses the following words:

> "The foundation business is a big business; and it would be reduced very seriously if the truth were generally known."

There is more on the same subject, but the above will be sufficient. I fear that friend Hasty has been staying at home so long he is becoming a little "hasty." I trust, however, he is not getting *uncharitable* as well, toward his fellow bee-keepers. Had he been present at the Keokuk convention he would certainly have written differently. I expressed a fear at that convention that bee-keepers were purchasing and using more foundation than was really profitable, and I asked the president to call for a large number of rising votes on the matter. I expected that many present would give us facts to show that so much foundation is not needed. Now, I hope that friend Hasty will believe me, even if some who do not know me so well will not, when I say that I have felt really troubled to see orders come in, especially during the past season, for such enormous quantities of foundation, especially for the brood-chamber. I like to do business where I can furnish my fellow-men with something they *really need* and that will be to them a profitable investment; but when it becomes necessary to keep the *truth* from being generally known, in order to push sales, *I do not want to do business any longer*. If friend Hasty is better prepared to give us the truth in regard to the matter than were the veterans at the above-mentioned convention, I will gladly give him space in GLEANINGS, and also pay him well for his time in writing it up. I can not believe that our journal would have reached its present circulation, nor our business its present magnitude, were it true that myself or any in my employ had tried to build up business by repressing the truth in regard to the things we have to sell. Ever since foundation began to be used by bee-keepers, there have been certain prominent writers who have been experimenting and writing to the effect that it does not pay to use it largely; and the matter has been under experiment and close scrutiny for at least ten or fifteen years. Our friend Doolittle has been prominent in this line. Now, if it is not profitable, especially for *novices* in the business, to invest so much money in this commodity, by all means let us have the truth out before another season opens.

A SIMPLE WAY OF GETTING AN ADJUSTABLE SPEED ON PRINTING-PRESSES OR OTHER MACHINERY.

THE ordinary way of doing the above is by countershaft and cone pulleys. One of our boys, however, three or four years ago, arranged a belt-shifter, so that he could, with his foot, throw the belt partly from the loose on to the tight pulley. By holding this belt-shifter where he placed it with his foot, he found he could get a very slow speed, and gradually increase it at any given point, clear up to the full normal speed of the press, simply by sliding the shifter a little further. We recently purchased an Armory press—a good deal larger than the one alluded to above; but he succeeds just as well in regulating the speed of this large press by the same cheap and simple device. In fact, his invention, if so it may be called, has saved us a set of cone pulleys that would have cost us $27.00, and the cheap arrangement is much simper and easier. One advantage is, that a green hand may run the press very slowly, while he is learning to feed, and then he can gradually give it a little more speed as his skill increases. I have wondered why this arrangement has not been used and mentioned before. If it has been, I have never heard of it. I invite the attention of our typographical periodicals to this labor and money saving device.

BURDENSOME NOMENCLATURE; GIVING CREDIT IN A NAME.

MR. HEDDON wishes to know why we do not give him credit by calling the Dovetailed the Dovetailed-Heddon hive. In the first place, it would make confusion with the *New* Heddon hive. More than that, to be fair to others we should have to call the hive the Langstroth-Blanton-Heddon-Danzenbaker-Hoffman-Hall Dovetailed hive. Life is too short to go through with all this. When the hive was brought out we gave credit to all four of the first named; and would any of our customers desire us to hitch on such a long-tailed appellation? We borrowed as much from Mr. Blanton and Mr. Danzenbaker as from Mr. Heddon, and more than all from Mr. Langstroth. Surely Langstroth's name should be attached if any. Every feature of the hive is old, and we do not claim for it any novelty in invention. The *dovetailing* has been in use for twelve years in hives, and the new hive itself is simply a combination of the old features that bee-keepers recognize and demand. In this connection I have always thought that the name of a well-known article, the Bingham & Hetherington uncapping-knife (a most excellent tool, by the way) was too long for convenience. Again, there used to be a hive sold which bore the name "VanDeusen-Nellis Simplicity Hive." It is a great convenience to use *short* names; and as we can't very well give credit to *all* in a name, why give credit to *any?* A *short* name which shall indicate some predominant or striking feature has preference and utility.

E. R.

TAKING A PARTNER.

In our work of following and studying the habits of many thousands of individuals on our ledgers, as the years pass by we learn many lessons. For instance, we see a young man starting in business, and we rejoice to see him steadily, year after year, build up a name for being prompt and reliable. We have also chronicled others who have their ups and downs, and a *few* who seem to be always in trouble. There is another class who start right, and do well for a time, but they have evidently become weary in well doing, and finally go all to pieces; and this latter class is what prompts this editorial. A good many, when they begin to get uneasy, or perhaps feel cramped for the time being, take in a partner, when the amount of business does not need any partner at all, but just the contrary. In fact, we have had so many letters telling sad stories as a consequence of going into partnership, that I have felt prompted to give this warning. When you take somebody in as a partner, you *trade off* a part of your *good name*—at least, you place it in somebody's power to spoil the good name you have worked hard for, for years. And a great many times, like partnership in bees, or bees on shares, both parties feel so sure they have each been swindled by the other, that they stick to it for the rest of their lives. When you have a great business—more than one man can control—it *may* be best to go into partnership. But even then I think it is far better to *first* employ your contemplated partner at a salary. When you have proved by experience that you can work together in harmony, then, but not before, go into partnership. By the way, why not make your *wife* a partner—yes, and children too? Friend Terry most earnestly enjoins *this* sort of partnership in his talk at farmers' institutes. Now, remember Uncle Amos "told you so."

SHALL PERIODICALS BE CONTINUED AFTER THE TIME PAID FOR?

It seems to me, dear friends, that there has been a great deal of useless discussion in regard to this matter. Most things of this kind are settled on the rule of the greatest good to the greatest number. Now, we can not decide what other publishers ought to do; but as we have found that at least nine out of ten of our subscribers prefer to have Gleanings kept going, we think we secure the greatest good to the greatest number by so doing. The tenth friend can easily be accommodated in two ways. First, he can say, when subscribing, "Send it only so long as the money pays for it." If he does this, and the publisher disobeys orders, he does it at his own risk, for he can not collect pay for sending it longer. If, however, this tenth brother omits or forgets to say any thing about stopping when he subscribes, and wishes to have it stopped, he can do so by writing on a postal card, "Please discontinue Gleanings." That will stop it. A good friend writes us that people are sometimes wronged in this way: Somebody makes you a present of a certain periodical. If the publisher keeps right on sending it, this friend is called upon to pay for something he never ordered at all. What shall you do in such a case? Well, I should say it is the publisher's loss if he continues to send his paper to anybody who never ordered it at all. The principal reason why we have been induced to send Gleanings longer than the time paid for is this: A great part of our readers mean to have Gleanings kept going; but they neglect, and put it off, and then in the same way neglect and put off having it started after it has been stopped. Such people always thank us very kindly for having it kept going without orders—that is, they do when they get around to it, say when they are ordering bee-hives or something of that sort. The world is full of people who neglect and put off things they *meant* to have done. Now, this weakness of humanity is a large and prevailing element in all kinds of business. Please note: If we stop the paper for everybody at the time paid for, this weakness harms the publisher and harms the subscriber; but by keeping the paper going until we have *orders* to stop it, this same unfortunate element is then on the other side of the scale. It then operates to the advantage of both publisher and reader. The only trouble about it is, the man who does not want the paper any longer must *say so*. If he continues to take it out of the office, and does not say so, the law, and it seems to me good common sense, dictates that he must pay for it. I omitted to say, in the proper place, that he does not even need to take the trouble to write a postal card. Let him just leave his journal in the office, and inform the postmaster that he does not wish to take it any more. The postmaster is then required by law to inform the publisher that so and so does not want the periodical any longer. So in reality *no one* is obliged to pay for a periodical unless he takes it out of the postoffice regularly; and exactly the same way you would be required to pay for any kind of goods you take regularly of the common carrier. If you or any of your family take a pint of milk of the milkman every day when he comes past your house, you are bound to pay him for it; and I believe it does not matter whether you ordered it or not. If you receive it out of his hands, you are responsible for its value. I have several times thought of mailing a postal card to each of our 10,000 subscribers, this postal card to be plainly addressed to us. On the opposite side we would have printed in large letters, "Do you want Gleanings continued?" All that our negligent friends will have to do in that case will be to write "yes" or "no" opposite the question; then we could go ahead with a fair understanding all around, and we should have all orders in black and white. The difficulties are that it would cost over $100 for the postal cards. Then it would cost over another hundred to place them in the hands of our readers, besides the large amount of laborious work on the part of our clerks and book-keepers, and very likely nearly half of our postals would never get dropped into the postoffice at all. But we do this, which is the next best thing to it: In every expired journal is put a circular letter, together with an order-blank and an envelope addressed to ourselves. The circular letter gives notice of expiration of subscription, and says, if you want the journal continued, fill out the blank and inclose it with one dollar in the addressed envelope. If you desire to have the journal stopped, write on the blank, "Please discontinue." If no notice is taken, the journal is continued, and in three months' time another notice is sent. If that doesn't "fetch 'em," another, in the course of time, is sent; and if still no response, we stop the journal, and send another notice to that effect, with a request to remit for the time not paid for. If our dropped subscriber still won't pay any attention, we don't trouble him further, as we do not care to waste more time. If we can afford to drop it there, he surely can.

productive, and an excellent pea in every respect, except that the pods look ready to pick before the peas inside are large enough to amount to any thing. If you pick them when they LOOK plump and full you will disappoint your customers, and have trouble. Get careful pickers; tell them not to pick a pod until they know by squeezing it that there are good-sized peas inside, and you will then call it, as we do, ahead in QUALITY of any other EARLY pea in the world.

American Wonder. ½ pt. 10c; pk. $1.75.
This is a cross between the Champion and the Little Gem. The vine grows from 6 to 8 inches high. It is the first to ripen among the green wrinkled sorts. On account of its dwarf habits it can be grown very easily under glass.

Stratagem. ½ pt. 10c; qt. 35c; pk. $2.00.
This has made its way rapidly in public favor. It is not only of rare excellence in quality, but the pods and peas are so large and fine looking they call attention at once from any thing else in the market. It has given us excellent satisfaction.

Champion of England. Pint, 15c; pk. $1.00; bushel, $3.50.
So well known as to need no recommend here.

Peas by mail will be at same rate as beans for postage.

PEPPERS.

Spanish Pepper. Oz. 25c.; lb. $2.50.
A new variety, so large that the natives of warm climates slice them up and fry, as an article of food.

Bullnose. Oz. 25c; lb. $2.50.
A larger variety than the above, but in every other respect the same.

Cayenne Pepper. Oz. 25c; lb. $2.50.
Much calle or, for seasoning soups, pickles, etc.

POTATOES.

Early Ohio.
The Experiment Station, Columbus, O., says there is nothing earlier.

Early Puritan.
Nearly as early as Early Ohio, and much more productive. Highly recommended by our Ohio Experiment Station. Prices: 1 lb. by mail, 25c; 3 lbs. 60c; 1 peck by express or freight, 50c; 1 bushel, $1.50.

Lee's Favorite.
This is a few days later than the foregoing, but yields better still. In our locality during 1889 it gave us over 100 bushels, from one-fourth of an acre.

Beauty of Hebron.
This is preferred by Terry because it gives as good, or better yield than any other, and comes off early enough to admit of getting in wheat in good time. It is a standard early sort.

Monroe Seedling.
Here is what T. B. Terry says in regard to them:

> Last season we had more perfect tubers in a bushel than I think I ever saw in any other variety of potatoes. They are strong growers, and do not sprout early; better quality than most late potatoes. I have returned 42 orders in one day since they were all sold. T. B. TERRY.
>
> Hudson, O., Oct. 22, 1890.

Prices of any of the above: 1 lb., by mail, 18 cts.; 3 lbs., 50 cts.; 1 lb., by express or freight, 7c; 1 peck by express or freight, 60 cts.; 1 bushel, $2.00. Barrel, $5 00. If potatoes are ordered in the winter, we will do our best to protect them from frost, but purchaser must take all risk.

Potato-eyes. Any of the above varieties by mail postpaid, 15c for 10; or $1.00 per 100.

PUMPKIN.

Early Sugar Pumpkin. Oz. 5c; lb. 50c.
This was selected from 13 different kinds of pumpkins. They aro specially designed for the first pumpkin pies of the season. Our strain of seed has been heretofore a good deal mixed. Last fall we had, however, a patch of many hundred, without a single large pumpkin in the lot. They are much earlier than the ordinary pumpkin, sweeter for pies, and so small in size that we sold them all along in the fall at the rate of two for a nickel. In many places people will pay more for early pumpkins for pies than they will for any kind of squashes.

Connecticut Field. ½ pint, 5c; quart, 15c; peck, 75c; bushel, $2.00. If wanted by mail, add at the rate of 16c per quart for postage.

RHUBARB.

tt's Victoria. Oz., 10c; lb., $1.50.

RADISHES.

Early Scarlet Globe. Pkt. 5c; oz. 10c; lb. $1.00.
This is the radish that Vick gives such a beautiful chromo of in his catalogue for 1888; and for forcing in the greenhouse, it is ahead of any other in the way of forcing radishes. They begin to form a bulb almost as soon as the second leaves come out. They are very hardy, and of exceedingly rapid growth.

Wood's Early Frame. Oz. 5c; lb. 50c.
The very best long radish for raising under glass, or for extra early.

Beckert's Chartier Radish. Oz. 5c.; lb. 50c.
A novelty, and one that has given us the greatest satisfaction; of rapid growth and good size, both at the bottom and top. In favorable soil it will grow to a large size, and still be excellent in quality. They are remarkably certain to make a good bulb.

Chinese Rose Winter. Oz. 5c; lb. 50c.
These not only stand cold weather until toward Christmas, but we consider them really a most delicious radish, and the most free from being corky, of any radish known. They are not as strong as radishes ordinarily are, but are of a sweet turnip flavor. Usually sown at the time we sow turnips.

SALSIFY, OR OYSTER PLANT.

New Mammoth. From Sandwich Islands. Oz. 10c; lb., $1.50.
We have grown this side by side with the common salsify, and we find the roots larger, better shaped, and equally good in other respects; they are, therefore, without question an improvement. Finely grown specimens are almost as large and smooth as parsnips.

SPINACH.

Bloomsdale Extra Curled. Oz. 5c; lb. 25c.
It combines as many of the good qualities as any other.

SQUASH.

SUMMER VARIETIES.

Golden Summer Crookneck. Oz. 5c; lb. 50c.

Giant Summer Crookneck. Oz. 10c; lb. $1.00.
This squash is as early as the ordinary crooknecks, and in every way equal; but are of such size that one squash will make a dinner, even when soft and tender; and one good thrifty plant will almost supply a family.

WINTER VARIETIES.

Hubbard. Oz. 5c; lb. 60c.
Too well known to need comment. We have tried nearly all the new squashes, but have not yet found a better one.

TOMATO.

Golden Queen Tomato. Pkt., 5c; oz., 25c; lb., $3.00.
This is no special novelty, that I know of, over other tomatoes, except its beautiful golden yellow color; but at the same time the tomato is good-sized, and remarkably smooth and regular. The quality is equal to any. Many specimens of the fruit have a rosy tint toward the blossom end, giving it something the appearance of a beautiful yellow peach with a slight blush of red.

Ignotum Tomato. ¼ oz. 10c; oz. 30c; lb. $3.50.
During the year 1889 we sent out about 3000 sample packages of the Ignotum tomato; and the general testimony of those who have grown it corroborates the decision of the Michigan Agricultural College, that it is, all things considered, the best, and they gave it a test side by side with over 100 different varieties. It has no rival that I know of in size, except the Mikado. There are, however, several kinds (among them Livingston's Beauty) that are rather handsomer in shape, but they are behind in size and earliness. In solidity the Ignotum is behind none; and for slicing up for the table we have never found any thing better.

Livingston's Beauty. Oz. 20c; lb. $2.00.
This is a production of the same Livingston who brought out the Acme, Trophy, Favorite, and Perfection; but he pronounces this superior to them all. They are better shaped and smoother than the Mikado, but not so large.

Pear-Shaped Tomatoes. Oz. 20c; lb. $2.50.
These are handsome for pickles and preserves. They are immense bearers, and of good quality.

TURNIP.

Extra-Early Turnips.

We have tested some of these which are advertised in the different seed catalogues; and while we find them some earlier than the staple turnips, they are, so far as we have tested them, inferior in quality, very strong in trste, and sometimes bitter.

Purple-top White-globe Turnip. Oz. 5 c.; lb. 40 c.
This turnip has given us the best results of any thing we tried; the quality seems to be unusually fine for table use, especially when they are about as large as fair-sized apples. They grow nearly as quick as any other turnip known, and are very handsome. When washed they are almost as white as an egg, with a beautiful purple around the top. They are smooth and round.

Yellow Aberdeen. Oz. 5c; lb. 40c.
We consider this one the best table turnip grown. When cooked it is so yellow that it will sometimes be mistaken for squash.

Breadstone. Oz. 10c; lb. $1.40.
During the past season this turnip was so much superior to any of the Swede turnips for table use, that those who ate them at our lunch-room came to me not only for turnips, but for seed to sow next year. The flesh is yellow, and the quality exceedingly rich and delicious.

White Egg. Oz. 5c; lb. 40c.
Very showy and handsome, as well as quite early, and fine quality. In 1890 they sold for 10c more a peck than the Purple-top Globe.

Southern Prize. Oz. 5c; lb. 50c.
For many years I have wondered if it were not possible to get a real turnip as strong growing and as hardy as the Seven-top. This we have finally secured, in the "Southern Prize." It stands all winter, even in Ohio, without protection: and, in fact, it seems to GROW all winter; and, best of all, it has a good-sized bulb (of fair quality) that winters over as completely as a parsnip.

SPECIAL NOTICES.

BROOD FRAMES WITH TOP-BAR DIVIDED.

Instead of fastening comb foundation to the wood comb-guide, some prefer to have the top-bar divided vertically, and place the sheet of foundation between the two sections; drive three or four one-inch nails through, and the foundation is secure. We can furnish thick-top Hoffman or closed-end frames, with divided tops, without extra charge, if mentioned in the order. Of course, no comb-guide will be included with these frames.

REMNANT PIECES.

Some six months ago we advertised some remnant pieces, 11 inches long by 2¾ wide by ¼ thick, planed on one side, at 25c per 100. They went off like "hot cakes," and were soon gone. We have since accumulated quite a good many more, which we offer, as long as they last, at the same price. If any of our readers have use for such pieces, here is a chance to get them cheap.

DISCOUNT FOR EARLY ORDERS.

A discount of 3 per cent is being allowed on all orders for goods listed on pages 10 to 27 of our new catalogue, received before Feb. 1st. During February, 2 per cent is allowed; after that date, no discount. Quite a number are availing themselves of the discount; others would do well to do so also. If any of our readers in Southern California intend to take advantage of carload rates of freight they must send their order at once, as the car we are now making up will start about Feb. 1.

5% DISCOUNT ON WIRE NETTING TILL FEB. 20.

By advice just received from the manufacturers of wire netting and fencing we are able to offer you a special discount of 5 % on the new prices in our Jan. 1st catalogue, until Feb. 20th. This is an inducement offered to get as many orders filled as possible before the rush of spring orders begins, and many should avail themselves of it. Send for our 20-page netting and fencing catalogue, and remember that on all orders received by Feb. 20th, an additional discount of 5 % may be deducted as well as those given on the discount sheet sent with the catalogue. This special 5% may be deducted also from the list of remnants on another page, for orders before Feb. 20th.

A NEW EXPRESS COMPANY IN MEDINA.

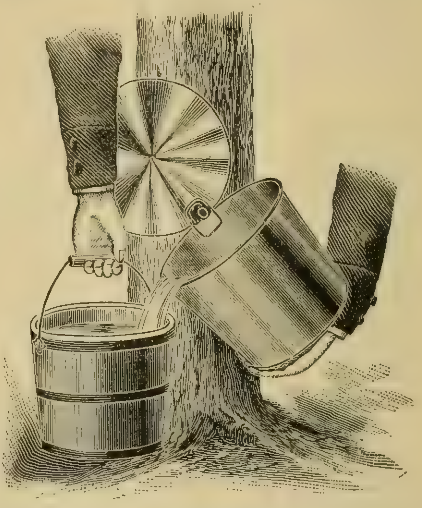
Trains have been running on the P., A. & W. from Medina west since Jan. 1, and the United States Express Co. has been doing business since the 10th. Connection has not yet been made from here east to Akron, but it will soon be completed. We are now able to send your express shipments by either the American or United States Exp. Co's; and if you have a preference, please state it in your order, or fill out the blank on the order sheet, telling what express company does business at your office, and we can decide which one to give the business to in order to secure you the best rates.

WIRE CLOTH FOR PROTECTING FRUIT-TREES.

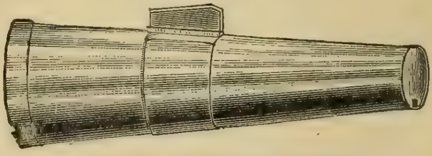
One of the men in our packing-room, Mr. H. A. Horn, who has a little place of his own, and raises fruit, tells me that young trees can be perfectly protected from rabbits, etc., by the use of our cheap wire cloth, so that the wlole expense, including labor and material, will not cost over a cent and a quarter per tree. Get the cheapest green wire cloth—even remnants will do. Cut it into strips 2 inches by 2 ft., or as near it as you can without much waste. Take one of these strips and wind it spirally around the tree from the ground up. No string, wire, nor any thing of the kind, will be needed to make it keep its place. Wind it on snug, and squeeze the last end closely around the tree with your hand, and it will stay. As the tree grows, the wire cloth will stretch as long as the protection is needed. He says he protected 250 trees in just two hours and a half. The cheap remnants offered in our table are just as good as any for the purpose.

SUGAR-MAKERS' SUPPLIES.

Maple-sugar-making time is at hand, and some are inquiring the price of supplies. First, you should supply yourself with that excellent book by Prof. Cook, "Maple Sugar and the Sugar-Bush;" price 35 cents; by mail, 38c. By studying this you may save many times the price of it. Notwithstanding the advance in the cost of tin, we are able to offer you sap-buckets and spiles and cans at last year's prices, as below:



Above cut shows a bucket hung on wire loop, with hinged tin cover, and manner of emptying.



IMPROVED RECORD SAP-SPOUT.

Record sap-spouts, $1.00 per 100; $8.00 per 1000.
10-qt. buckets, IC tin, $15.00 per 100; IX tin, $17.00.
12-qt. buckets, IC tin, $16.00 per 100; IX tin, $18.00.
Patent hinged covers, $6.00 per 100. Reversible wood covers, $4.50 per 100. Wire loops for wood pails, 30c per 100: for tin pails, 25c per 100. 1-gal. square cans, 50 or 100 in a crate, $12.00 per 100. Boxed 10 in a box, for re-shipment when filled, $1.50 per box; $14.00 for 10 boxes.

BACK NUMBERS OF GLEANINGS CHEAP.

We have quite a large quantity of old back numbers of GLEANINGS, containing much valuable reading-matter. As our list of readers is constantly growing larger, there are no doubt a good many who have been readers but a comparatively short time. If any of these desire to use these long winter evenings by reading up on the subject covered by GLEANINGS, here is an opportunity to get a good deal of reading-matter for a small amount. We can send you a large variety of back numbers, no two alike (unless you are not particular, and want to use them for distribution), at one cent each, in lots of 10 numbers or more, by mail postpaid, or by freight with other goods, as you choose.

FRUIT-TREE PRUNERS.

It is time you who have fruit-trees were preparing to prune and trim them, ready for next season's crop. Authorities differ on the best time for pruning; but it is generally conceded that it is better to prune any time than not at all. Probably more pruning is done in February and March than any other time of year.

SMITH'S COMBINED PRUNING SHEARS AND SAW.

Above we show a very convenient tool for pruning. The shear is used for cutting off small limbs up to about ⅝ inch. For those larger, the saw is used. The regular price is $2.00; but we will sell samples, to introduce them, at $1.50; or to those who will canvass their neighborhood we will make a special price of $13.2 per doz., net, cash with the order. The handle is 6 ft. long. A single one will go best by express; ½ dozen or more, by freight. If any prefer to furnish their own poles we will send them for 10c each less without the pole. A little pamphlet of instructions about pruning is included with each machine, and they are all sharpened ready for use when you get them.

PRICE OF COMB AND EXTRACTED HONEY.

We have received only a few orders for honey since our quotations of a month ago. This is largely due to the holiday season; but it has occurred to us that may be we make too much difference in the price of large and small quantities; we therefore make revised quotations as follows:

No. of cases of two 60-lb. cans.	Less th'n 2	2 to 5	5 or more
White Sage, extracted, liquid......	10	9	8½
Light Amber, " candied s'l'd	9	8	7½
Amber, " "	8½	7½	7
No. 2 amber, " "	8	7	6½
Choice white comb honey, 1-lb. sec.	19	18	17½
Good " " " " "	18	17	16½
Fair " " " " "	17	16	15½
Dark comb " " " "	16	15	14

The same grade of 2-lb. sections, 2 cents per lb. less than 1-lb. Some seem to be afraid to order comb honey during cold weather. In lots of 5 cases or over, we put it in a crate with straw in the bottom, and handles to carry it by, so that it can not be roughly handled. The 1-lb. sections are in 12, 24, and 48 lb. cases. The price quoted above is on 24-lb. cases. Two 12-lbs. will count one, and one 48-lb. counts two toward the quantity price. Samples of any grade of extracted honey mailed free to intending purchasers, so that you may not be disappointed in what you are getting, but may know exactly what it is before ordering. Those who haven't sufficient honey to supply their own neighborhood will do well to supply themselves. We had a letter from a pioneer in the business of peddling honey among consumers, which we are not allowed to print. We can not forbear to say in this connection, that he, with two helpers, bought and disposed of enough honey in about 3½ months to clear $2500. He got a large part of his supply from us, and praises the white-sage honey very highly. Some of our readers who have the time might be improving it to their profit in the same way during these winter months.

1891. EARLY ITALIAN QUEENS from bees bred for business. Try my strain of 7 yrs. breeding. The extra honey stored will more than pay her cost. Each $1.00: six, $4.50. Ready in May. If you prefer, order now and pay when queens arrive.

Maple Sugar and The Sugar-Bush

THIS IS A NEW BOOK BY
PROF. A. J. COOK,
AUTHOR OF THE
BEE-KEEPER'S GUIDE, INJURIOUS INSECTS OF MICHIGAN, ETC.

The name of the author is enough of itself to recommend any book to almost any people; but this one on Maple Sugar is written in Prof. Cook's happiest style. It is

PROFUSELY ✻ ILLUSTRATED.

And all the difficult points in regard to making the very best quality of Maple Syrup and Maple Sugar are very fully explained. All recent inventions in apparatus, and methods of making this delicious product of the farm, are fully described.

PRICE: 35 Cts.; by Mail, 38 Cts.

A. I. ROOT, Medina, Ohio.

KIND WORDS FROM OUR CUSTOMERS.

HAND CULTIVATORS AND SEED-SOWERS.

The "Special Department for A. I. Root" is the most interesting part of GLEANINGS for me now. I wish he would tell what he knows about the Planet Jr. tools. in that department, soon. It may interest others as well as me. Will the drill sow beets, carrots, parsnips, and radish seed, and drill peas evenly? Are the other tools practical? They cost too much to buy and not use them. I have been doing all my sowing by hand. It is taking too much of my time. I should think the cultivator would take a good bit of strength to push it.

Butler, Pa., Jan. 1. J. J. SHANOR.

[Friend S., we are special agents for all the Planet tools; but for all that, I will try to answer you without bias. The Planet seed-sowers, we regard as the best of any thing there is in the market; in fact, it is the only seed-sower I know of that will sow every thing, and never get clogged or make a failure; at least, we have never had such a thing happen. The hand cultivators, like all other tools to be worked by hand, need considerable strength unless your ground is in very nice order. Where there is ground enough, and your rows can be far enough apart, I would by all means use a horse. For uneven ground, or for ground that is not thoroughly pulverized, a wheel-hoe with a larger wheel we find easier to manage. We are using one made by one of our bee-friends. It has a wheel perhaps 2½ feet across, that we like better than the Planet tools, but only on account of the larger wheel. The tool mentioned is made by G. W. Cole, Canton, Ill., who expects to advertise it in our next issue.]

DISCOUNTS FOR EARLY ORDERS.

As is our usual custom, we are allowing a liberal discount on orders sent in now for goods to be used next season. After the vexatious delays last spring, it is needless to explain the many advantages secured by those who order early. Not only do you gain by having your goods to put together and get ready for use during leisure time in the winter months all ready for business in the spring, but you secure a sufficient discount to make the investment a profitable one. You also run the chance of getting better goods, made when we are not so rushed, than some we were obliged to send out last spring, made by unskilled workmen on the night force during the "great rush" for supplies. With the increased capacity that our new two-story brick building, 37 x 100 feet, gives us we hope to be better prepared than ever for such an unusual increase of business as we have had the past season. Still, the experience of the past two years has taught that it is not safe to rest with too much confidence on this reasonably good prospect. It is much safer for you to ORDER EARLY. We have secured from Michigan over 100,000 feet of basswood, out of which we are making the whitest and nicest sections we ever turned out. To verify our word, send 5 cents to pay postage on a sample. With a demand equal to last year, the sections made from this lot will be gone by April 1. We may get more equally good, but the chances are in favor of those who order early. Our new revised catalogue is ready to mail on application.

DISCOUNTS.

The discounts will apply to every thing in our catalogue ordered for next season's use. They can not, of course, apply to large orders for counter goods or honey-packages; but if only a few of them are included with an order for hives, etc., then the discount may be taken from the whole bill.

Up to Dec. 1st, discount will be 5 per cent. After that date, one per cent a month for each month before March; i. e., 4 per cent in December, 3 per cent in January, and 2 per cent in February.

A. I. ROOT, Medina, O.

NEW FACTORY.

On or about Feb. 10, 1891, we will move into our new factory, built exclusively for the manufacture and sale of

APIARIAN SUPPLIES,

located in Ottumwa, Wapello Co., Iowa, where we will manufacture and sell all kinds of Apiarian Supplies at the lowest possible prices, after the above date. Write for illustrated catalogue, to 1tfd

GREGORY BROS. & SON,
Farragut, Fremont Co., Ia.

Wants or Exchange Department.

2-tfdb Williamson, N.Y.

WANTED.—To exchange, 1 saw, with counter-shaft and belt. Will exchange for wax.
2-3d L. L. ESENHOWER, Reading, Pa.

WANTED.—At "Chatsworth Apiary," one hundred and fifty pounds of bees, and fifty tested Italian or Albino queens, to be delivered on or before May 20th. 2d HORACE BANKS, 2103 Oak Ave.,
Baltimore, Md.

Job Lot of Wire Netting.

CUT PIECES AT A LOWER PRICE THAN FULL ROLLS.

Having bought from the factory, at our own price, five or six hundred remnants, as listed below, we are able to give you the choice of a great variety of pieces at the price of a full roll or lower. Full rolls of netting are 150 ft. long, and when they are cut we have to charge nearly double the full-roll rate, because it is so much trouble to unroll, measure, and cut, and run the risk of having a lot of remnants on hand. No doubt it is in this way that the following remnants have accumulated. It costs a good deal to get all this in shape so we can easily pick out from the lot the piece you want. But to move it off quickly, we put the price down so you can all have a chance at it. Remember, first come, first served. In ordering, therefore, name a second or third choice, or say that we may send the nearest we can if the piece selected is gone. On 5 pieces deduct 5 per cent, on 10 pieces 10 per cent. These remnants are shipped only from here. If any of you want to secure some, and don't want them shipped till later, when you will order something else, so as to save freight, pick out the pieces you want, send remittance with the order, with request to lay by till called for, and we will mark them as belonging to you. We prefer to ship them right out, however.

LIST OF POULTRY-NETTING REMNANTS.

Width in in's.	Size of Mesh.	No. of Wire.	Cts. p'r Sq. Ft.	Length of each piece. Multiply by the width in feet to get the number of square feet in each piece. Then multiply by the price per foot for the price per piece.

18	8	13	2	68 ft.; 36 in., 200 ft. at 4c; 45 in., 247 ft. at 5c.

Four and eight inch fencing. Price in fourth column is the price per foot in length.

A. I. ROOT, Medina, O.

HONEY COLUMN.

CITY MARKETS.

ALBANY.—*Honey.*—We have received up to date 2144 cases of comb and 222 packages of extracted honey. The demand is moderate at present, but we look for a good trade in extracted during February. Prices remain unchanged. White clover, 1-lb. boxes, 16@18; same, 2-lb. boxes, 14@16; buckwheat, 1-lb. boxes, 12@13c; same, 2-lb. boxes, 11@12c. Extracted, light, 9@10; dark, 7@8.

CHAS. MCCULLOCH & CO.,
Jan. 12. 339 Broadway, Albany, N. Y.

CINCINNATI.—*Honey.*—There is a good demand for all kinds of extracted honey, with a full supply on the market of all but Southern, which is scarce. It brings 6@8c a lb. on arrival. Demand is fair for choice comb honey, which we hold at 16@20c in the jobbing way. *Beeswax.*—There is a good demand at 24@26 for good to choice yellow on arrival.

Jan. 8. CHAS. F. MUTH & SON, Cincinnati, O.

KANSAS CITY.—*Honey.*—Comb or extracted not selling as fast as we should like to see it. Market quiet. We quote white 1-lb. comb at 16@18; dark, 12@13; white, 2 lbs., 14@15; dark, 11@12. Extracted, 6@7. *Beeswax*, 25. CLEMONS, MASON & CO.,
Jan. 9. Kansas City, Mo.

ST. LOUIS.—*Honey.*—The situation is unchanged. Extracted and strained honey are in good inquiry at from 5½@6½. Comb, 15@16 for medium light; 17@18 for white. *Beeswax*, prime, 25½c.

Jan. 8. D. G. TUTT GRO. CO.,
St. Louis, Mo.

BOSTON.—*Honey.*—While honey is selling slowly it is well for us that it is so, for we have the smallest stock on hand that we have had for years. Prices are being well maintained, and the supply will be entirely exhausted before the first day of March. Best 1-lb. comb selling at 19@20c; fair to good, 18@19. No 2 lb. in stock. Extracted, 7½@9. No beeswax.

BLAKE & RIPLEY,
Jan. 9. Boston, Mass.

NEW YORK.—*Honey.*—We have nearly sold out all of our comb honey. Market very quiet. We quote extracted basswood at from 8@9c; Fla., at 8@8½c; California, 7@7½c. *Beeswax* scarce; 28@30c, according to quality and color.

F. G. STROHMEYER & CO.,
Jan. 8. New York City, N. Y.

ALBANY.—*Honey.*—The honey market is quiet and steady, with light stocks of any kind or grade. Comb honey is selling at—white, 16@18c; mixed, 14@15c; dark, 12@14c. Extracted honey—white, 9@10c; mixed, 7@8c; dark, 6@7. *Beeswax*, 28@32c. We just sold what extracted honey we had from Iowa at 9½c. This seems to be the most staple honey nowadays.

Jan. 2. H. R. WRIGHT, Albany, N. Y.

CHICAGO.—*Honey.*—Trade is slow at this date, which is usually the case so soon after the holidays. Prices are easier on anything falling short of choice. Comb, 17@18c; off color, 13@15c. Extracted, 7@8c. *Beeswax*, 27c for prime. Receipts are moderate, yet quite up to this time last year. R. A. BURNETT,
Jan. 7. 161 So. Water St., Chicago. Ill.

DETROIT.—*Honey.*—Comb honey is in better supply, and selling at 15@17c; first quality white clover scarce. Extracted, 7@9c. *Beeswax* in good demand at 27@28.

Bell Branch, Mich., Jan. 9. M. H. HUNT.

FOR SALE.—500 lbs. white-clover extracted honey. Price 9 cts. in 1-gallon tin cans. G. L. JONES,
Grand Ridge, La Salle Co., Ill.

WANTED.—One or two thousand pounds of nice comb honey. Write, giving amount on hand and price wanted. A. D. ELLINGWOOD, Berlin Falls, N. H.
17tfdb

FOR SALE.—Choice honey in sections, cans, and C. pails. Send for price list to OLIVER FOSTER,
12-tfdb. Mt. Vernon, Ia.

FOR SALE.—1200 lbs. extracted white-clover honey in barrels or 60-lb. cans, as desired.
1tfdb E. J. BAXTER, Nauvoo, Ill.

FOR SALE.—2000 lbs. comb honey in 12 and 24 lb. crates. 2d L. WERNER, Edwardsville, Ill.

CONVENTION NOTICES.

The Vermont Bee-keepers' Association will hold their annual meeting in the parlors of the Addison House, Middlebury, Vt., Jan. 28, 1891. J. H. LARRABEE, Sec'y.
Larrabee's Point, Vt.

The 8th semi-annual meeting of the Susquehanna County Bee-keepers' Association will be held at Montrose, Pa., Thursday, May 7, 1891. H. M. SEELEY, Sec'y.
Harford, Pa.

The annual meeting of the Ohio State Bee-keepers' Association will be held in Toledo, Ohio, on Tuesday and Wednesday, Feb. 10 and 11, 1891. Full particulars as to railroad and hotel rates, and place of meeting, will be given later. Let all interested in bee-keeping make an extra effort to be present.

Bedford, O. MISS DEMA BENNETT, Sec'y.

The Eastern Iowa Bee keepers' Association will meet Feb. 11 and 12, 1891, in Maquoketa, Iowa, at the Dobson Town-clock Building, to commence punctually at 10 A.M. There will be a large turn-out of the prominent bee-keepers of the State. There will be a question-box, free to all, in which any question that you wish discussed can be presented and answered. Let all be on hand, and bring in your report for 1890, spring count, or from May 1. The people of Maquoketa kindly furnish us a free hall. FRANK COVERDALE, Sec.

PROGRAM OF THE NEW YORK STATE BEE-KEEPERS' CONVENTION.

First day, January 22, 2 P.M.

Call to order. Reports of secretary, treasurer, and standing committees. Reception of new members, and payment of dues.

"Exhibits of bees and honey at fairs."—Thomas G. Newman, Chicago, Ill.

MISCELLANEOUS.

7 P. M. "Outdoor wintering of bees."—J. E. Crane, Middlebury, Vt.

TOPICS FOR DISCUSSION.

"The proper thickness of comb foundation."

"Is it advisable to use full sheets or starters in brood frames?"

QUESTION-BOX.

Second day, Friday, January 23, 9 A.M.

Appointment of committees.

"Shallow vs. deep brood-chambers; narrow spacing and fixed distances."—N. D. West, Middleburgh, N. Y.

TOPIC FOR DISCUSSION.

"Are we ready to adopt a standard for the American Italian bee? and if so, what are the dsirable characteristics?"

QUESTION-BOX.

1:30 P.M. Receiving new members. Election of officers.

PRESIDENT'S ADDRESS.

"What constitutes a good bee-journal?"—W. F. Clarke, Guelph, Canada.

"Queen-excluders for comb and extracted honey."—J. H. Martin, Hartford, N. Y.

MISCELLANEOUS.

7 P.M. "How has the new tariff affected our branch of agriculture? Free sugar vs. extracted honey for manufacturers."—F. B. Thurber, New York.

"What our market demands."—Henry Segelken, New York.

QUESTION-BOX.

Saturday, January 24, 9 A.M.

MISCELLANEOUS.

"Artificial heat to prevent brood-rearing."—Samuel Cushman, Pawtucket, R. I.

"New uses of queen-excluding zinc boards."—F. H. Cyrenius, Oswego, N. Y.

QUESTION-BOX.

1:30 P.M. "Bee-escapes: their uses and advantages."—C. H. Dibbern, Milan, Ill.

Reports of committees. Miscellaneous business.

P. H. ELWOOD, Pres. G. H. KNICKERBOCKER, Sec.

☞The Eastern New York Bee-keepers' Association will meet conjointly with the above—same time and place.

THOS. PIERCE, Pres. W. S. WARD, Sec.

PRICE LISTS RECEIVED.

Since our last issue we have received price lists of bees, hives, and apiarian supplies in general, from the following parties:

Geo. E. Hilton, Newago, Mich.
M. H. Hunt, Bell Branch, Mich.
M. S. Roop, Council Bluffs, Iowa.
The G. B. Lewis Co., Watertown, Wis.

The following are from our press:

F. W. Lamm, Somerville, O.
Miller Bros., Bluffton, Mo.
G. W. Cook, Spring Hill, Kansas.

ALL YOU

who are in want of Sections, Bee-hives, etc., berry-baskets, or crates, set up or in the flat, please give us a trial order. 2d **J. B. MURREY, Ada, O.**

GLEANINGS IN BEE CULTURE.

DEVOTED TO BEES, HONEY, & HOME INTERESTS.

Vol. XIX. **JAN. 15, 1891.** **No. 2.**

TERMS: $1.00 PER ANNUM, IN ADVANCE; 2 Copies for $1.90; 3 for $2.75; 5 for $4.00; 10 or more, 75 cts. each. Single number, 5 cts. Additions to clubs may be made at club rates. Above are all to be sent to ONE POSTOFFICE.

Established in 1873.
PUBLISHED SEMI-MONTHLY BY
A. I. ROOT, MEDINA, OHIO.

Clubs to different postoffices, NOT LESS than 90 cts. each. Sent postpaid, in the U. S. and Canadas. To all other countries of the Universal Postal Union, 18 cts. per year extra. To all countries NOT of the U. P. U., 42 cts. per year extra.

STRAY STRAWS

FROM DR. C. C. MILLER.

How are your bees wintering?

NEW-YEAR'S DAY—rain; very unusual.

THE AMERICAN BEE JOURNAL, in its new form, is very neat.

NEWMAN is calling the roll of the dead or missing bee-journals.

HONEY has 12 to 23 per cent—normally 18 to 21 per cent—of water; the rest is sugar.

MY INTRODUCING-CAGE beats McIntyre's when you get a queen from abroad, or take a queen to an out-apiary.

THE *British Bee Journal* is a rather loose affair. It is never stitched together. It's not loose in its views, though.

McINTYRE'S INTRODUCING-CAGE is ahead of mine for changing a queen from one hive to another in the same apiary.

CYPRIANS AND HOLY-LANDS are not much talked about nowadays. Does any large honey-producer use them exclusively?

TEA-LEAVES kept in pans of water are recommended for drinking-places for bees, by W. Woodley, in *British Bee Journal.*

THE INDEX of the *American Bee Journal* deserves commendation for giving with each subject the name of the author.

DOOLITTLE says, "If you wish a large yield of section honey, keep prolific queens, and let the brood-combs alone, after they are once filled with brood in the spring."

QUEENLESSNESS, according to Doolittle, in the *American Bee Journal*, can never be detected from the outside, if the bees have the means of raising a queen. Thus the few things I thought I knew about bees are diminishing in number.

BEES IN CELLARS are always quieter—at least mine are—just after a windy time, whether cold or warm. A still, muggy time is worst. Don't tell me cellars need no ventilation.

OUTSIDE CASES for wintering are among the things that I meant to have tried this winter. I'm "dreffut" anxious to know how those 28 at Medina pull through the winter, if we have any winter.

"STRAY SWARMS" is what "Observer," in *Canadian Bee Journal*, calls this page. He says, "I venture the opinion that it will be an interesting page." I always did think "Observer" was venturesome, and lacking in judgment.

BEES HANGING OUT can be made to "go in and attend to business, simply by the use of a smoker," according to the A B C. I don't believe a word of it. I tried it lots of times. They'll go in, of course; but does it make any difference in their work?

ADULTERATION IN AUSTRALIA was deprecated at a meeting of bee-keepers there, where it was declared, "Large quantities of an article labeled 'honey' are manufactured here, in which there is not a fractional part of real honey—in some cases none at all."

BRITISH WEATHER has been unusually severe. In England, Nov. 28, the thermometer marked 5 above zero—"twenty-seven degrees of frost," as they call it—a very rare thing, and snow covered the ground from two inches to two feet. The *British Bee Journal* says, "Indications everywhere point to the probabilities of an exceptionally severe winter."

BINDERS for GLEANINGS and other papers I've thrown aside. When the year is up, I put the numbers straight together and get some one to hold them so, while I drive in, and entirely through, three two-inch wire nails, at the right place to stitch them together. Each nail is drawn out just as I want to sew the cord through the hole m ade by the nail.

A RECORD-BOOK is a thing I shouldn't like to be without. I've started mine for 1891 already. I keep in it all sorts of memoranda of interest. Mine's about 13 by 6, costs 25 cents, and lasts a year for 300 or 400 colonies. Each colony has its place in numerical order, three colonies on a page.

"OBSERVER," in *Canadian Bee Journal*, thinks too much time was taken up at Keokuk with "flowery nothings." I always did think "Observer" was a person of good judgment. But, "Observer," it isn't pretty to say, "Americans pay but little heed to any thing Canadians want." What do you want?

INCORPORATION OF THE NORTH AMERICAN under State laws, troubles the *Canadian Bee Journal*. It thinks incorporation by Congress would make it more what its name signifies. Why, bless you, Mac, the point of incorporation doesn't limit its field of occupation. Washington isn't as near Canada as Springfield.

A GOOD ONE on A. I. Root! Cheshire says, "My own bee-house long since came under the chopper; but Mr. Root thinks well of the house-apiary," and then quotes about a page in its favor from the A B C. Friend Root, I don't pity you one bit. You've no business to let such misleading things stand in a standard work.

BEE-JOURNALS AT COST is what the *Review* hints every bee-paper but the *Review* is. Some have undoubtedly been issued at less than cost, but the standard journals, at least part of them, either lie egregiously or they make a good thing of it, independently of the supply-trade. I'm sure they give us both sides of every question too. Look here, W. Z., you keep on making a good paper, and let the others alone. If you don't, I'll tell on you about advertising "cream" for sale, and then not even furnishing skim-milk. The others furnish the supplies they advertise.

MOUNTAIN LAUREL, *Kalmia latifolia*, is the plant that yields poisonous honey. Cheshire says it grows in "damp places," and adds, "Happily, our American cousins are now never likely thus to suffer, thanks to drainage, the plow, and the bee-farm." For a man who is so exacting as to other authors, isn't that a bit reckless? If he were to see it growing among the rocks of my native hills in Western Pennsylvania, he'd change his views. "Damp places," where the ground runs nearly straight up! Some of those pebbles 6 feet through would hinder a plow.

TEMPERATURE IN CELLARS is higher at top than at bottom. Macpherson, of *Canadian Bee Journal*, reports a visit to Allen Pringle's cellar, where two thermometers are kept, one at top, the other at bottom. At top it was 48°; at bottom, 42°; a difference of 6°. I never found so much difference as this and other reports make. I have just been trying my cellar. I put in two thermometers. Each showed 46°. Then the thermometers changed places. Top, 48°; bottom, 44°—a difference, you see, of 2° between the top and bottom of cellar, and a difference of 2° in the thermometers.

[Now, look here, doctor. You have been thus far very quiet and peaceable, and, as a rule, respectful, bundling around among your "straws;" but when you say that you do not believe a word of something I tell you, and which has been told for years in the A B C book, I think it time to stir a little myself. A good many times a new swarm will hang on the outside of the hive, and not go to work. In such a case I would put a comb with a little unsealed brood inside, then with a smoker make them crawl in; and when they find the brood, and find what a nice place they have, they usually pitch in and behave as the orthodox have always done with the "shining" hour. Another thing, our good friend Cheshire made a mistake and you turned right in with him. If both of you will read the opening remarks in regard to the house-apiary, you will find a string of objections, and something like the following: "Most apiarists prefer to work in the open air, to being cramped up in a building." Again, "In a building we are obliged to get the bees out of the room every time we open a hive, and bees are very untidy when crushed by careless footsteps," etc. What rickety thermometers you must keep in your cellar! I hope you did not buy them of any respectable supply-dealer.]

GENERAL CORRESPONDENCE.

SEVERAL QUESTIONS IN QUEEN-REARING ANSWERED.

DOOLITTLE REVIEWS THE MATTER.

The following questions have been sent in for answers; and to simplify matters I will number the questions and answers.

1. Why does not all the progeny of a black queen, mated with an Italian drone, or an Italian queen mated with a black drone, show the same markings?

2. Will the eggs and larvæ of a queen two months old produce as good queens as if she were one or two years old? If not, why not?

3. If we make a colony queenless, removing all the eggs and brood, and give this queenless colony a comb containing 1000 eggs, not nearly as many queen-cells and cells of capped brood will be found on the tenth day as we gave eggs. What becomes of the eggs? If destroyed, why? If used in the jelly given the queen larva, would the eggs of a black queen affect the coloring of the young queen reared from Italian larva?

4. What is the least number of days after hatching, the weather being favorable, required before a young queen will leave the hive for fertilization?

5. Will there be any difference in the time of leaving the hive for fertilization, between a queen hatched in 10 and one hatched in 16 days?

6. How many days after hatching, before the worker-bee leaves for labor?

7. In what does their first outdoor labor consist—gathering honey, pollen, water, or propolis?

8. Will a queen reared from an old queen about to be superseded be as good as when reared from the same queen in her prime?

1. For the same reason that *no* "blood" of two different colorings can be mixed and have the progeny of the mixture show a uniform coloring. Take any of our animals, the sheep, the hog, the cattle, horse, dog, cat, etc.; birds of all colors as to feathering; or the vegetable kingdom, and we find the same laws governing them in this matter of coloring, just the same as we find regarding the bees. Plant Marblehead and Hubbard squashes side by side, so that the bees can mix the pollen in the blossoms of each, and see what a mixture of color you will get as a result. If the progeny of a mismated queen should show a uniformity of coloring, bees would be an exception to the laws governing the most of animated creation.

2. According to the prevailing opinions of others, no; but according to the most careful observation on my part, yes. After years of careful watching along this line, I fail to see any difference between a queen raised from the very first eggs laid by any queen, and those laid by the same queen two years later; and I do not believe there is any difference. Will those who doubt this fact tell us wherein the

difference lies, giving facts to support their ideas? Has any one noticed that the first workers hatched from any queen were in the least inferior to those produced by the same queen later on in life, every thing otherwise being in a normal condition? The size of the cradle and the amount of food given govern this matter. it seems to me, rather than the age of the queen.

3. Some of the eggs are removed to give place to the larger and more commodious queen-cells. Why more than these are removed I do not know, unless it is because the colony is thrown into an abnormal condition. As to what becomes of the eggs, I have no hesitation in saying that the bees eat them; for I have repeatedly seen bees eating eggs as they came from the queen. Because the bees eat eggs, it does not necessarily follow that they in any way enter into the food given to the young queen larva, for, according to my observations, thousands of eggs are eaten by the bees when they have no idea of rearing queens. And if they did enter into the royal jelly they could only form so small a part of the whole that little or no chance as to coloring could be given. But if, as nearly all claim, this royal jelly is an animal secretion, how could it possibly affect the color of the young queens, even if the royal jelly was formed wholly from a diet of eggs from black queens? I had supposed the old Kirby theory was exploded long ago. From many years of experience, I have failed to find that black nurses, or eggs or larvæ from a black queen, in a hive from which Italian queens were being reared, had any thing to do with the coloring of such queens.

4. Five days after maturity is the least number that I ever knew to elapse before the queen went out to meet the drones. But a queen does not always hatch on her maturity, for very many are held in their cells from one to five days by the worker bees, after they would have gnawed off the capping to their cell and come out, could they have had their own way. Queens are more often held in their cells in this way than is generally supposed. In one instance I opened a hive and found a young queen piping away with a vehemence I had never known before. After looking the hive over I found a queen-cell with a queen in it which I had overlooked when cutting out cells from this hive some time before. As there was plenty of bees in this hive I took the frame having this cell upon it, bees and all, and set it in an empty hive, together with a frame of honey, thus forming a nucleus. The queen from this cell took her wedding-flight successfully the next day; and in two days more, or three days in all from the time I set the sealed cell in the hive, she was laying worker eggs regularly in the comb which her cradle was on. This is a fact, and is as I have it down in one of my diaries. I told it at a bee-convention once, not explaining the aforesaid maturity part, and no one would believe it. Thus it will be seen that the days from *hatching* are not a safe guide to go by.

5. Yes; the queen hatched in 10 days will, as a rule, be slower in going out. In round numbers, 3 days in the egg form, 6 days in the larva form, and 7 days in the sealed state, is the rule for all queens from a colony in a normal condition. Thus it will be seen that the queen which hatches in 10 days must have been from a larva at least 3 days old, when the bees commenced to change it from a worker to a queen. Nine-day queens are very slow in being fertilized, while, out of a batch of queens which once hatched in 8½ days, only two became fertile at all; one being fertilized after she was 20 days old. These queens could scarcely be told from a worker, and neither lived to be over three months old.

6. They can be forced out at three to four days old; but when the colony is in a normal condition, 16 days is the rule. For observations along this line, proving the same to be facts, see back volumes of the different bee-papers.

7. Either or all, just according to the wants of the colony, and according to the supply to be had from the fields.

8. Yes; and I would add, that some of the best queens I ever had in my apiary were reared by this superseding process, the old queen living from one day to one year after the young queen, or the queen-cell for her, was started. The answer to question 2 will hold good here. I have never seen any difference in queens or workers reared from queens about to cease life, as compared with the same from the same queen when in her prime. Has any one else? If so, will he please tell us about it?

Borodino, N. Y., Jan. 1. G. M. DOOLITTLE.

[In regard to Qu. 3, where queenless colonies are given a comb full of eggs, the latter are surely not *always* destroyed; for at one time we practiced this plan for getting cells, nearly a whole season; and I did not particularly notice the disappearance at the time, although I have noticed something of the kind since. Will others who have experimented particularly in this line let us know about it?]

THE HOFFMAN FRAME.

THE NEW HEDDON HIVE.

Friend Root:—According to my promise to you at the Keokuk convention, I will give you my experience for the last 8 years with the "Hoffman frame." My first bees were hived on Root's metal-cornered frames, in Simplicity hives. I soon found, however, that they were too light and frail. They would sag down when well filled with brood or honey, and I soon replaced them with the Hoffman frame, of which I procured a sample to work by, from friend Hoffman himself, or friend Nellis, I have forgotten which. I found them far superior to the metal-cornered frame—no sagging, and, what was of decided advantage to me then, as I was engaged in migratory bee-keeping, was the ease and dispatch with which I could prepare full colonies for transportation; and, later on, when engaged largely in raising and shipping queens and nuclei, I found nothing to equal them for safety and convenience in shipping; and at the present, while I am engaged in raising comb and extracted honey in out-apiaries, they fill the bill to my satisfaction, though they are not quite so convenient as the closed-end frames in the horizontally divisible brood-chamber, as used by friend Heddon in his new hive, of which I have 50 or more in use at present.

While using the Hoffman frame for the past eight years, as stated above, I have used all-wood dovetailed frames of different thickness and width, some sawed for wiring, some pierced for wiring, and some without wire, and none have given the satisfaction the Hoffman frame has. Why, then, not adopt it exclusively? For this reason: Their cost. My principal business for the last six years has been that of raising and selling queens, three-frame nuclei, and full colonies of bees; and the prices I have been compelled to sell at have prohibited the use of so costly a frame as the Hoffman.

Now, however, as I am raising honey on the out-apiary plan, I shall use the Hoffman frame and Dovetailed hive, in connection with the new style of Heddon hive, with its fixed frames;

and I may say here, that, with specialists who make handling bees their sole vocation, the new Heddon hive is one of the best, if not *the* best, ever devised, so far as my limited experience goes. Why not adopt and use it exclusively, then, instead of the Hoffman frame and 8-frame Dovetailed hive? Same reason—cost. Another is, the new Heddon hive and frame are not standard, and the Hoffman frame and Dovetailed hive are, and you can not fill orders for nuclei or full colonies as readily as you can with the Hoffman frame. This may look like advertising the divisible-brood-chamber hive; but I do not mean it so; but friend Root can strike it out, if he thinks best, though, as friend B. Taylor, of Forestville, Minn., has used for 20 years such a hive, and demonstrated by great crops of honey its advantages, its merits should be more generally known.

Another and great advantage of the Hoffman frame is the ease and certainty of correct spacing; and this, to one who handles many frames (and especially at out-apiaries, where the time to work with the bees is limited, if you return home the same day, and the distance is great), is of great advantage, as I have proven to my complete satisfaction, as one can do more than double the work in a given time, and do it far more correctly.

I think I have said enough on this subject to convince any one of the advantages of a fixed frame that is a standard L. frame also, and I am sure none who gives it a fair trial will reject it. The only objection is their first cost; but they are well worth all they cost, to one who expects to make a living by raising honey, and especially those situated as I am, who, in order to get a fair crop of honey, *have* to run out-apiaries. E. T. Flanagan.

Belleville, Ill., Dec. 26.

[The Hoffman frame used to cost anywhere from $3.00 to $3.50 per 100; but now they can be obtained for $2.00 per 100 almost anywhere, or, in quantity, for less money yet. The matter of *cost*, then, does not figure as largely as it did. I would rather use a *good* frame at double the cost than a poor frame that costs half the money.

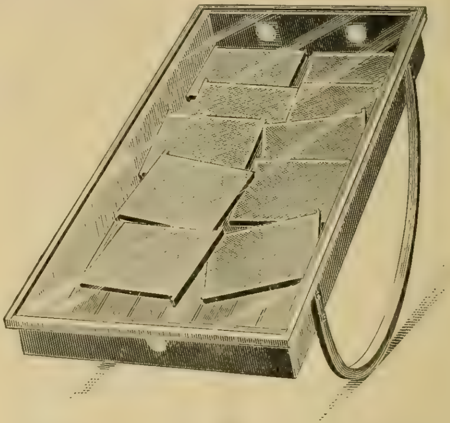
That's all right about the new Heddon hive. We want the truth. If it has merit, let it be sung.]

THE SOLAR WAX-EXTRACTOR AND HONEY-EVAPORATOR.

H. R. BOARDMAN'S DEVICE.

In Gleanings of Oct. 1, Mr. S. F. Newman notices, in a very complimentary way, my "improved solar wax-extractor." I almost think I ought to apologize for not responding sooner to your request to tell all about it in Gleanings; but I have been delaying in hopes of being able to send a picture of it or a model. I made a mammoth solar extractor about two years ago, that was illustrated and described in Gleanings. This did the work well, but had no very easy means of adjustment. It was imperfect, heavy, and clumsy to handle. I was satisfied with the principle, but not with the manner of its construction. After spending considerable time in dreaming and experimenting I wrought out the "invention" to which Mr. Newman calls your attention.

The improvement consists in mounting upon rockers instead of wheels, by which means it can be adjusted, or turned, with perfect ease. It also dispenses with the chamber at the lower end, for holding the wax-pan. In fact, it is little more than a plain shallow box with a few modifications, covered with glass, and adjusted at an inclination to the sun, for its heat. The combs are thrown into this box, when the wax is melted and runs down the inclined bottom, leaving the residue. The wax can be drawn off or allowed to cool, when it can be removed. The lower end of the extractor is covered, so that it leaves it in the shape of A. I. Root's bread-pan feeders with sloping sides, so that it really combines the wax-pan with the extractor.



BOARDMAN'S SOLAR WAX-EXTRACTOR, IMPROVED.

There are ventilators in each end covered with wire cloth, that can be opened or closed at pleasure, when used as an evaporator.

I am sure that Mr. Newman does not overrate its merits. It has been a success with me, not only as a wax-extractor, but for evaporating and melting honey.

It is an old chestnut, that granulating is the test of purity in honey. I am using honey on my table now that is clear and limpid, that has been treated only by being placed in this evaporator for a while at the close of the honey season. This is the only extracted honey I have ever been willing to say I thought equal to comb honey. Isn't this the secret of some of the California honey not candying? I suspect it is.

No, I have not got them to sell, but I could make them on short notice, if wanted. I can not say definitely what they would cost, but they would not be expensive. I think they would cost some less in proportion to their size than the small ones now in use. Of course, it is not patented.

I have had some difficulty in finding just the right material for the inside, or lining. Wood seems to do as well as any thing I have tried. It must be of narrow stuff, matched, and well painted a drab color. The only objection I have found to wood is, it shrinks, from the constant heat it is subject to. Tin does nicely, but does not absorb heat as does something of dark color. I have tried paint on tin and iron linings, but they do not hold paint as well as wood. The hot wax dissolves or softens the paint, and it scrapes loose in cleaning out the residue, or "slum gum," as our California friends say. Mr. Doolittle advises the use of Russia iron; but iron will not do. I have rejected a lining of Russia iron, after giving it a thorough trial, on account of its discoloring the wax. It won't do to use iron when it comes in contact with melted wax. H. R. Boardman.

East Townsend, Ohio, Dec. 5.

[You have no doubt presented the bee-keeping fraternity with a valuable implement; and although the idea is not new, you have simplified its manner of construction. As a solar wax-extractor and honey-evaporator, it is probably ahead of any thing else before the public, in the way of cheapness, utility, and convenience. For a small solar wax-extractor alone, we like the Doolittle style the best; but for wholesale melting, yours is perhaps the better. We shall probably get orders for them; but if friend Boardman has any idea of making them, and will make them and offer them for sale, we shall be glad to leave the field entirely open to him, so far as we are concerned.]

PAINTED VS. UNPAINTED HIVES.

WHITEWASH AS A SUBSTITUTE; WHY THE DOVETAILED JOINT IS SUPERIOR TO EVERY THING ELSE IN CALIFORNIA.

In March 15th GLEANINGS, 1889, Mr. Doolittle has an article advocating unpainted hives, saying that, as the paint prevents evaporation of moisture, painted hives are much more damp and cold, and that bees in the unpainted ones will swarm from one to two weeks earlier in the spring. A. I. Root, in his footnotes, recalls the fact that he had often seen water running out of painted hives, and says he is pretty sure there would have been no such ice and condensation had the hive been unpainted. Thinking over the matter I remembered that, in my painted hives, I had had many combs rotted by mildew. I was increasing my apiary rapidly at that time, and had many hives to build. I decided not to paint them. The interior valleys of California are hot. Where my apiary is, the mercury often registers in the shade 110° Fahrenheit for eight hours a day and eight days at a time. Well, this heat on my black unpainted hives causes the combs to melt down *en masse* unless the hive is shaded or very much ventilated. One day in July, one of these hot days came. I had wilted in the morning as soon as the sun hit me; and, though knowing that my bees needed extra ventilation, I lay under the dense shade of an oak and read "King Solomon's Mines." In the evening I crawled off to look at the bees, and it seemed to me there was a creek of honey running out of the entrance of all the unpainted hives in my apiary. I lost some forty colonies outright, and there were many others badly damaged. The white painted hives stood the ordeal vastly better, though even in them, when the entrance was not full width of hive (like your Dovetailed hive), there were some combs melted down. My combs were mostly new ones, and very full of honey. After that disastrous experience I whitewashed my hives, and I now believe that that is the proper treatment for them, as it combines both the advantages of the painted and the unpainted hives. The whitewash does not prevent evaporation of moisture; and by giving a fresh coat each spring the hives much surpass in whiteness, and therefore in coolness, a painted hive, especially if it has not been painted for two or three years. Mr. Doolittle, too, seems to have had some unfavorable experience with unpainted hives since writing his article of March 15, 1889; for, May 15, 1890, one year and two months after, he closes a letter by saying he now "prefers to paint his hives and let them stand in the sun."

Your Dovetailed hives, both in body and style of cover, are well suited for this climate, as nails alone will not prevent boards from warping here.

This has been an unfortunate year for me in several respects, commencing with the going to pieces of my fine apiary from excessive swarming, so that I got less than half as much honey as I should have done. Next a Dago sets out a brush fire one hot August day, and in the conflagration which ensued, 21 of my hives of bees were burned, and many more melted down. I saw the fellow set out the fire; and as he refused to pay damages, which he was well able to do, I prosecuted him; but he came to court with some of his countrymen, and, by perjury, convinced the jury that he was asleep under a tree at the time the fire started. He has recently served a notice on me, telling me to keep my bees from coming on his land, claiming that they destroy the *grass*. WM. G. HEWES.

Newhall, Cal., Dec. 20.

[You have given us a valuable article. The evidence that you present for hives painted white or whitewashed, as against hives unpainted, is convincing; for certainly no one could have had a better opportunity to observe the comparative differences. Dr. C. C. Miller does not paint his hives. He argues, if they will last him fifteen years, he can afford to throw away his old hives that have never been painted, and buy another set, because the money saved in paint and time will buy the new hives. Besides that, he would have all the advantages of modern improvements in the new hives. The testimony of bee-keepers generally is against having hives unpainted. It is generally supposed that whitewash will not preserve wood. If prepared right and put on right, I think it will. At this point I stopped and talked with an experienced mason—one who served an apprenticeship of seven years in England. He says that whitewash will preserve wood. Its mode of preparation for outdoor work is as follows: To three pounds of lime add one pound of cheap grease, and then add hot water until it is of the right consistency. It should be put on the wood while it is hot. If put on when it is cold it is liable to rub off and soil clothing. Many years ago we used a whitewash made of water lime and skim-milk, to cover our old American hives. This seemed to hang to rough unplaned wood very well, but we discarded it because it did not look as neat and tidy as hives that were planed and painted. Whitewash will perhaps prevent melting down of combs as effectually as white paint. It is not only very cheap, but it can be applied with a whitewash-brush.

If any hive will stand it without painting, it is the Dovetailed; and I have no doubt that the lock corner, as some prefer to call it, will stand a great deal more than any other in a climate like that of California. Some of the bee-papers argued that there was no need of a stronger corner. Our own apiary, and my observation of other apiaries, show that there is such a need; and in California it is a necessity. It is too bad that you could not get hold of that Dago. They are rather "tough" citizens, and it is often better to get along with them with as little trouble as possible.] E. R.

THE BEET-SUGAR INDUSTRY OF THE UNITED STATES.

ONE OF OUR CORRESPONDENTS GIVES US A GLIMPSE OF WHAT IS GOING ON.

Friend Root:—In a recent issue of GLEANINGS, some one intimated that beet sugar is not as pure as that manufactured from cane. We have been using beet sugar made at Grand Island, this State, and it is good enough for us—in fact, we think it is much whiter and sweeter than granulated sugar obtained elsewhere. I have taken pains to get a sample of beet sugar manufactured at the factory at Grand Island, and send the same to you to-day by this mail. If you do not pronounce it equal to or at least as pure as any in your market, I am mistaken in your good judgment. I know by actual experiment that it will do for feeding bees; it is fully as good as cane sugar.

At Norfolk, in this county, a beet-sugar factory has been erected, which, when completed, will be the largest in the world, and perhaps the day is not far distant when you and your readers will *call* for Nebraska sugar-beet sugar.

Nature has not been very lavish with her gifts, but she has given us soil in which are grown the finest beets in the world; and according to government analysis they contain the greatest amount of saccharine matter.

I send you a paper containing an account of the great enterprise at Norfolk. A. C. TYRREL.

Madison, Neb., Dec. 20.

[The sample of sugar received is certainly equal to any thing I have ever seen or tasted. The granules are perhaps a little larger than ordinary, but they are as clear and white as pieces of the clearest ice, and remarkably pure to the taste, and free from any thing suggesting the brown or cheap sugar. As so much interest has been expressed in this matter, we have thought best to make an extract as follows, from the paper which friend T. was so kind as to send us—*The Norfolk News:*]

HOW BEET SUGAR IS MADE BY THE DIFFUSION PROCESS.

The *News* can perhaps give a better idea of the "diffusion" process of sugar-making employed by the Oxnards, and of what the new factory at Norfolk will do, by inviting its readers to follow the beets from the farmers' wagons and cars, through the various processes, until the beautiful granulated sugar drops in three grades of fineness into bags or barrels ready for the table or otherwise.

The beets are stored in huge bins, with a V-shaped bottom terminating abruptly over a canal that runs along its entire length, the bottom being composed of short planks which can be removed when it is desired to let the beets drop down into the canal. As wanted, the short planks are lifted up, and the beets drop down into the canal. A rapid stream of water floats them along, soaking and washing them as they go, until they reach the building. Here they are dipped out by a great bucket-wheel which spills the water back into the canal, and carries the beets up and drops them upon a chute, which takes them through the wall of the main building and into one end of a long cistern, say three feet deep and wide. In this a shaft with wooden arms, set in a spiral, stirs the beets in the water and keeps moving them toward the other end. Here a broad-bladed screw, set slanting, lifts the beets out of the water; carries them up and drops them inside an immense cylinder, which gives them many whirls in water and drops them out at its elevated end. Next they pass over a long platform made up of cylinders covered with stiff bristles revolving in opposite directions. These brush out the last vestige of soil in the depressions of the beets as the beets glide over them, and they drop off clean into a chute which carries them through a wall and lands them in a perpendicular elevator with buckets which carry the beets to the top of the main room, where a chute conducts them into a receptacle, standing on scales, which tips them out as often as 2200 pounds drop in. Thence they slide into the mill, which cuts them, a ton in three minutes, into little corrugated strips as large as a hen's quill, and two to four inches long. These strips are called "cossetts," a technical French name which answers as well as any. If ground fine or into thin shavings they would pack in the diffusion cells and not let the water run through freely. Next they slide into the diffusion cells, which may be three or four feet in diameter, and eight or ten feet high, and hold one to one and a half tons of pulped beets. A number of these cells arranged and connected with each other is called a diffusion battery, just as several cups used in galvanic electricity are called a battery. The successive cells are usually numbered 1, 2, 3, 4, etc. Each cell has a cap, or cover, which can be turned to one side, or be closed air-tight when put in place, with rubber under the outer rim, and brought down with a powerful lever screw. The flat bottom is similarly closed, but has a false bottom a little above it—a strong copper plate full of fine holes. A metal hot-water pipe enters the top just below the cover. Another similar pipe below runs out from the open space between the bottom and the perforated false bottom. This ascends and enters the top of cell No. 2, and in doing so passes through a steam pipe or chest. From No. 2 a similar pipe runs to No. 3, and so on through any number of cells in the battery. The tops of the cells being opened, they are filled with the cossetts, or strips of beets, and the covers are fastened down. Hot water is then let in through the pipe, the required pressure being obtained by placing the hot-water tank at any desired height. As will be seen, the hot water passes down through the contents of cell 1; then out at the bottom and up over into the top of cell No. 2, and down through its contents, and so on through the other cells. The water, being cooled in passing through the material, is heated in the steam-chests. In practice, thermometers on these indicate by a dial on the outside when the liquid is of the desired temperature, and the attendant turns the steam on or off from any steam-chest as needed. The same water passes through all the cells, often obtaining all the sugar it can dissolve before reaching the last one. By the time ten or twelve successive waters have passed through cell No. 1, all the sugar is extracted, its bottom is opened, the exhausted cossetts are dropped into a large receptacle below, and new material is put in. The fresh-water inlet pipe is changed to No. 2, and No. 1 becomes No. 12, or the last of the series, the saturated juice leaving this. Cell No. 2 having already had 11 doses of water passed through it, the first supply of fresh water passing through it removes its last vestige of sugar. It is then refilled with fresh pulp, and becomes No. 12 of the series, No. 1 becoming No. 11. So the process goes on round and round. The sugar-saturated liquid from the diffusion battery and its receiving-tank is carried into great tall tanks, in which the sweet liquid is mixed with milk of lime, which unites with and destroys native acids in the beets, and other impurities. After a while the carbonic-acid gas which was caught from the kilns which burn the lime on the spot (outside), to make the milk of lime with, is let in through the liquid, and unites with and solidifies any excess of lime not already solidified. This liquid is then carried off into the filter room, where it passes through a remarkable series of filters, which remove the lime and other impurities. The clear liquid-looking-like thin molasses then flows down into shorter tanks, where a little more lime is added to remove any acids escaping the first liming. It is then again pumped to a set of clean filters in the filtering-room, and comes back into the main room to be pumped as required into the great condensing boilers, four in number. The great air-pump removes the air and steam produced inside the first boiler, so that the liquid boils down very rapidly at a low temperature, 135° to 140° Fah. After partial condensation the liquid passes to the second for further concentration; then into the third and finally into the fourth. The heat and pressure of each succeeding boiler are regulated to the increasing density of the syrup. From the last condenser, the concentrated syrup passes into large reservoir tanks, and is next pumped into the "vacuum pans," which are really great air-tight, upright cylinders, from which air-pumps exhaust the rising steam. In these vacuum pans the syrup becomes a thick mass of sugar crystals and molasses. From these, buckets carry the mass and drop it into the "centrifugals." These are iron cylinders, say 3 feet high and 4 feet in diameter, the outer rim covered with fine brass wire cloth. Part are working while the others are being emptied and re-supplied. They revolve about 1000 times a minute, the outer rim traveling 10,000 to 12,000 feet, or over 2 miles a minute! The sugar flies against the outside, and in two or three minutes all the molasses is thrown through the wire gauze, and drops into a receptacle below, to be further treated and concentrated, and to produce another lot of crystallized sugar. The sugar, now white, is sprayed with a forcible jet of mixed air and cold water, all of which flies through the gauze, leaving the sugar a mass of clean white grains, a trifle damp. The bottom is opened, the sugar drops into a receptacle below, whence it is taken by a screw elevator into the drying-room.

Here is a 30-feet-long revolving cylinder, 5 or 6 feet in diameter, sloping downward. Its inner surface is full of little shelves, while in the center is a small cylinder kept warm with steam inside of it. As the sugar is brought up from the centrifugals, it drops into the elevated end of the great cylinder. It is picked up by the little shelves, and when they come around to the top (as the cylinder slowly revolves) they drop the sugar off upon the inner warm cylinder, which dries it, and it falls off to be picked up by other shelves and carried up again. As this cylinder stands sloping, the dry sugar works down toward the far open end. This end terminates in a rim of fine brass wire, next to which is one of a coarser mesh. All the fine-grain sugar, composing a great deal of it, now entirely dry, falls through the fine wire and goes down a chute into barrels or bags in the shipping-room below. The next grade in fineness passes through the next screen, and falls down another chute. The coarsest grains fall out of the end into a third chute.

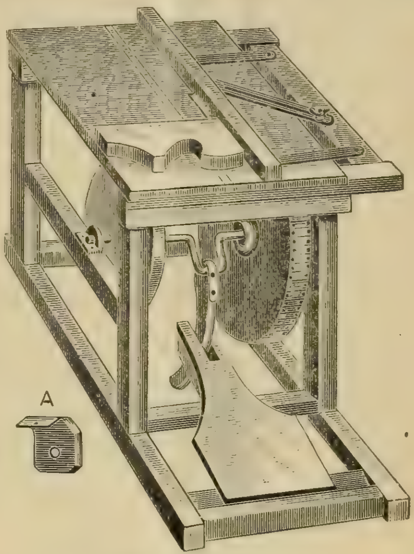
An interesting arrangement is the current of air sucked through the long cylinder from the far end, which takes up moist vapor from the drying sugar and some fine sugar dust. This air is driven through a long room with partitions nearly across, first from one side and then from the other, twenty or thirty of them. These check and cool the current of air, and all the fine sugar dust drops on the floor as pure sugar flour. It is usually re-dissolved and concentrated, and crystallized into coarser grains through the centrifugals, so nothing is lost. Even the molasses is mainly worked into sugar unless it shall be worth more in the syrup form.

[To indicate something in regard to the present demand for the seed of sugar beets, I will mention that, while visiting Ferry's immense seedhouse in Detroit, I saw stacked up in one of their great rooms such a vast quantity of seeds in bags that I asked the guide in astonishment what it was for which there could be such a demand. He told me that it was sugar-beet seed from France, and that they had just put in two shiploads. We have for several years past raised the beets on our own grounds, just for the fun of it. As visitors go through our fields I frequently cut off a piece of beet, and cut it into little strips, and pass it around. The visitors always make exclamations of surprise. The real sugar beet, in the right kind of soil, is almost as sweet as the licorice-root which children get at the stores. No wonder they get sugar from it in immense quantities by simply washing it out from the beets with pure water, by the diffusion process, so plainly described above.]

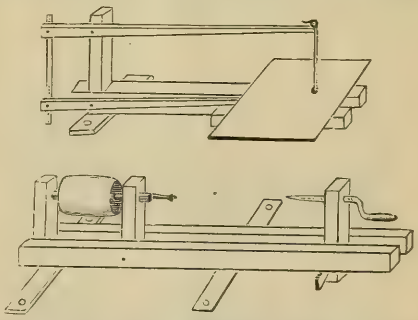
THE STEWART HOME-MADE SAW-TABLE.

PLAIN INSTRUCTIONS HOW TO MAKE ONE WITH A TURNING-LATHE AND SAW ATTACHMENT.

Mr. Root:—As per your request I send herewith a sketch of my home-made saw-table, with lathe and scroll-saw attachments. The framework of my saw-table is made of 2x2½-inch scantling, and is 28 in. square. The sills are 18 in. longer in front, for hinging the treadle. The frame is mortised together, and pinned. The tread-hinge consists of a piece of scantling with a hole in each end, and is just long enough to go between the sills. A hole is bored in each sill, and a hickory pin driven through the sill and into the end of the tread-hinge. The treadle is made of a ¾-in. board, 8 in. wide, securely nailed to the hinge, and is tapered to 3 in. wide at the end where the pitman is attached. A block in the shape of a wedge is securely nailed on the under side of the narrow end of the treadle, with a mortise for the pitman. The pitman is hard wood, with an iron cuff. The crank-shaft is a ¾-inch iron rod. The crank has a six-inch sweep. The drum that runs the mandrel is 22 in. in diameter, with a three-inch face. The wheel at the left is 15 in., and runs the lathe and scroll-saw. They are fastened on with taps and washers. The table is made of inch boards nailed to two pieces of scantling, 4 in. longer than the frame. The parallel bar is so hinged that it can be raised and turned over, and will hang down on the right side of the table when not in use. A space 1½ in. wide is left in the table for the cut-off gauge, which is made of two pieces, one the length of the table, 1x1½ in., the other 1x6 in., tapered to 3 in. at the end to the left, and nailed securely together at right angles. The table is held in place by a pin in each corner, and can be lifted off or on in an instant. The mandrel is the one you sell for $3.50, and is fastened on to two pieces let in at each end in the top pieces of the frame. The saws are six-inch rip and cut off.



A HOME-MADE SAW-TABLE.



SCROLL-SAW AND TURNING-LATHE ATTACHMENT.

I have some home-made cutter-heads for beading, and making small moldings. They have but one bit. They are made of a block of hard wood, 2 inches square, and an inch thick, with three corners cut off (see A at the left of the saw-table). The bit is fastened on with a screw. Through the center for the saw-arbor I bore with an inch bit, ⅛ inch deep, and then bore through with a ⅝-inch bit. The washer that goes on between the nut and the saw must be left off, as this block would not let the nut go on if you use the washer. There is a stud set on the piece of framing that crosses under the treadle and under the top piece of the frame. This, and the front corner-post are the hangers for the crank for the scroll-saw. A 1¼-inch hole is bored in the top piece of the frame for the pitman for scroll-saw. This stud, wheel, and pitman, are not shown in the drawing. I use Rogers' saw-clamps. The arms are fastened on with bolts threaded to within one inch of the head; one tap between the arm and standard, and one tap on the other side of the standard. The table, and also the saw, are removed when using the scroll-saw or lathe attachments.

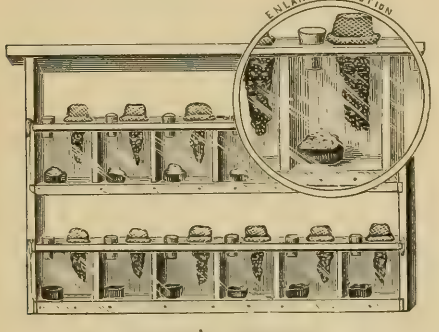
Sonoraville, Ga., Dec. 3. R. W. J. STEWART.

[Many thanks, friend S., for your excellent and explicit instructions, together with the sketches, which show almost at a glance how the whole thing is made. There are many of our geniuses who will readily be able to make a home-made buzz-saw; and many of our farmers, of a mechanical turn of mind, during the odd days of winter, when their time is not worth much, can construct one to advantage. There are others who would make one, even though the machine would cost more in the end, just for the fun there is in it, and the after-satisfaction of showing it to their friends. W. Z. Hutchinson, of the *Review*, a few years ago made a home-made saw-table. Others have done so. But the one above is perhaps as simple as any.]

GOLDEN'S CELL-HATCHER.

HOW TO CONSTRUCT AND USE.

Friend Root:—I send you to-day a photograph of my queen-hatcher and protector. This I believe to be the handiest and most common-sense device ever used. One glance at the device as shown will undoubtedly convince any queen-breeder of its utility and feasibility, from the building of a cell to the disposing of the queen. Having used a number of them the past season, and to some extent last year, and from a practical knowledge, I can heartily recommend them as above claimed.



GOLDEN'S HATCHER.

To make, take a brood-frame; remove the bottom-bar. Fasten horizontally, as above, 4 bars ⅛ inch wider than the end-bars, spaced two inches, the ⅛ inch projecting on one side, or front of the frame. The upright division pieces are the same width as the end-bars, and spaced, also, two inches apart. A strip of tin is tacked on each lower bar, and forms a sort of groove, or rabbet, for the glass front to rest in, held in place by a small button at each upper corner. A wood separator is tacked on the back. Before putting together, the bars are spaced, and two holes are bored to each compartment. The little trays to hold the good candy or honey are made by dipping a square-pointed stick in cold water, then in melted resin and beeswax, equal parts, then pressing to the bottom of the vessel of water, making a flat bottom to the little tray. When putting them into the compartments, warm them, and press them in place. They will seldom get loose, and will not leak or get out of shape. The wire cap is fastened at the back side of the frame by a small wire, which answers as a hinge. The cap protects the cell from the bees, and, when a hatched, the young queens are often fed through the meshes, by the bees.

The hole with the cork in is used to drop honey into the little trays, and to dampen the Good candy when it becomes dry. To liberate a queen, throw back the wire cap; lay your cage over the hole, and the queen will immediately ascend thereto.

The device is easily constructed, is always ready, and is adapted to all stages of a queen, from the egg by the Doolittle plan to its maturity, and may be kept an indefinite time in any colony.

The device answers most admirably in feeding sugar candy, or stimulating for early brood. For feeding, place squares of soft candy in each compartment, and tack on a one-inch strip of a wood separator in place of the glass front. The wood is warmer than zinc, and the bees have better access to the candy.

Some one may say that the bees will build comb in the spaces above and below the cages. I answer, they might do so; but in two seasons' practice I have never had a particle of comb built or even started. J. A. GOLDEN.

Reinersville, O.

[Your device is very similar to one used by Henry Alley and also by A. E. Manum. You will find the latter described and illustrated on page 629, Aug. 1, 1889. Instead of using the little wax-tray, Mr. Manum takes bits of combs and cuts one side clear down to its base. This rests horizontally on the bottom of the cage, the sliced-off side down. It is more convenient to get the queen out of one of your cages, and also, I think, to insert a queen-cell. All these devices have been used for years, and are on the same general plan. They answer their purpose very well.] E. R.

OUTSIDE WINTER REPOSITORIES.

HOW TO PREVENT THE ROOF-BOARDS FROM BECOMING MOIST, AND SO ROTTING.

I wish to thank Mr. Doolittle for his kind comments, in GLEANINGS of Dec. 15, page 876. I desire to say to Bro. D., that I believe our cellar will last longer than he apprehends, for two reasons: 1. Because there is no dampness as yet, noticeable on the sides and top: 2. Because I used very heavy oak timbers for covering. There are four 4x6 stringers laid on edge lengthwise on the top, and across these I laid two thicknesses of oak slabs, that are from two to three inches thick. On these I placed a layer of rye straw, to keep the dirt from rattling through. Up to date the bees are wintering nicely in it. The roof timbers are dry, as I proved by scratching matches on them. We keep the temperature at 40° by opening or closing some of the doors. Our eight-inch ventilator seems to draw out the moist air. Perhaps the fact that Mr. Doolittle's cellar was two feet lower in the ceiling than ours, and that he did not have as much ventilation, will account for its being so moist as to rot the timbers. It may be that, when very cold weather comes, and we shall be obliged to close our ventilator, the moisture may then collect as it did in his.

I think the discussion of such repositories is profitable, for the reason there are so many bee-keepers who need something of this kind. I am ashamed to tell it, but it is true, that I have lost in the past what I believe would have amounted to hundreds of dollars in bees and honey by trying to shift along without proper facilities for wintering. In the future I expect to place about two-thirds of my stock in out-cellars, and winter one-third outside in Bristol-Langstroth hives. I am trying twelve of them this winter.

Now, Mr. Root, every once in a while some bee-journal gives Gleanings a dig, or criticises some of your methods. With all its faults I would not give up Gleanings for the whole of them. Gleanings is the friend and helper of all bee-keepers, old and young, big and little. All such squibs remind me of a fly attacking an elephant. The best thing they can do is to let "that corner" alone. Harry Lathrop.

Browntown, Wis., Dec. 25.

[The reason that moisture condenses upon a surface is because the latter is colder than the surrounding air. We find evidences of this almost every day on the windows in winter. If these surfaces can be kept as warm as the air inside, no moisture will condense. The boards forming the roof, or support to the dirt, of Mr. Doolittle's repository, were rather thin compared with the great mass of dirt above. This conveyed its lower temperature through the boards, and caused them to be colder than the air inside, and consequently to collect drops of water. The flagging-stones, subsequently adopted by Mr. Doolittle, being a better conductor of heat or cold, were little if any better—in fact, I think worse, on account of the moisture, although, of course, they would not rot. Your roof, being 6 inches through to the dirt, would form a good non-conductor, and hence would collect no moisture, even without the ventilator. At any rate, it would be interesting for you to try it and report.

DEVELOPING A HOME MARKET.

THE EFFECT OF A HONEY ADVERTISEMENT IN GLEANINGS.

While some advocate building up home markets for honey, I should like to tell my experience. Several years ago I undertook to increase the demand for honey by leaving some with nearly every merchant in the towns around me, so as to bring it before the eyes of everybody. I was delighted at the prospect of selling large crops in the future. But what was my surprise when, one year ago last September, I found every one of those merchants well supplied with honey before there was a demand for it. Evidently I built up a market for others which left me out in the cold, with a large crop on hand. You see, the year was a good one, and the farmer had honey, and sold it for what he could get. But I learned through Gleanings that the crop was short in the East, so I told the editor that I had honey to sell. Before long I had inquiries and offers from 7 or 8 different States, and I soon sold more honey than I had. I bought, and sent away all I could get; and before spring I had a demand for my partly filled sections.

This year would be a good time to build up a home market, as very few farmers have honey to sell. But I still receive calls from that ad't in Gleanings, and some of them are such that I can't refuse, while I have honey; neither can I keep still and not let you know what is expected of the readers of Gleanings. Credit to whom credit is due.

A few months ago I had a call for honey from a firm in Indianapolis. We agreed on the price. He offered to pay cash in advance. I was afraid the quality of my honey was not what he expected, so I wrote him like this:

"I suppose you have looked me up in regard to my standing, or you would not have made that cash-in-advance offer. If you will send me the price of 100 lbs. I will send that amount—a fair sample of what I have."

In a few days the money came, and with it a letter saying:

"We never inquire into the standing of a bee-keeper who reads Gleanings and raises honey to sell such a year as this."

I think all who responded to that advertisement gave credit by saying, "I saw your advertisement in Gleanings." One neglected to sign his name. I had no more honey to sell, but wanted to answer that letter, and did not know how.

HOW TO KEEP THE ENTRANCE CLEAR IN THE CELLAR.

If the back of the hive is 4 inches higher than the front, slope 4 in 20, the entrance will not clog with dead bees. The hives can be tiered up by sliding the next back three or four inches. I have three cellars tiered that way, and they never need looking after. I have practiced it several years. J. Handle.

Savanna, Ill., Jan. 2.

BEES AND FRUIT.

VALUABLE TESTIMONY OF A FRUIT-GROWER.

Dear Bro. Root:—The question was recently asked me by a neighbor of my friend Dr. N. Q. Higbie, "Do bees injure fruit?" Now, Bro. Higbie keeps some 60 swarms of bees, while the neighbor in question keeps none; and there seems to be a very prevalent idea among those who are unfamiliar with honey-bees and their nature that their presence, in large numbers at least, works an injury to fruit-blossoms which very materially lessens the following crop of fruit. My answer to the gentleman was a very emphatic "No, sir." "But," said I, "on the contrary I consider the bees a very important adjunct to the various natural agencies which are brought to bear in the developing of a bountiful fruit crop. Having been for a number of years engaged in growing small fruits for market, I have come to see the value of bees to such an extent that I have purchased a few colonies, and intend to increase the number."

If fruit-growers understood the botanical structure of fruit-blossoms thoroughly they would recognize more readily the agency of bees in the fertilization of blossoms. Many of us are familiar with these things, but by far the greater number know or think but little about them; and it is for the good of the latter class that I write this.

If, for instance, we take the blossom of the common cherry, as an illustration, we find it is composed of the calyx, or outer covering of the bud; immediately inside of this comes the corolla, with its several petals of white. Now, when this flower is opened and spread out in all its beauty and natural perfection before us, we shall notice, in the center of this, numerous small hairlike projections, called stamens; and, exactly in the center, the pistil, which terminates in a small bulb at the bottom, which is to become the fruit. Now, the numerous stamens produce pollen, which is inclosed in minute anthers at the head of the stamens, and is the fertilizing matter which must be brought in contact with the stigma, or top of the pistil. Thus the ovules, or seed-vessels, are fertilized, or impregnated, and develop into perfect fruit. One of the agencies for the proper distribution of pollen is the wind; but sometimes if we happen to have a few still days during the blossoming period this would be inadequate to the designed purpose; so nature has placed a little drop of sweet deep down in the flower, at the base of the stamen; and our little friend the bee comes flitting about in search of nectar for his future winter store, and, discovering the tempting morsel, he literally stands on his head in an effort to reach it, and in so doing his back becomes dusted with pollen from the stamens; and as he reaches down into the flower his back is brought in direct contact with the pistil of the flower, thus performing a very important work in nature's great panorama.

Who has not noticed bees coming into their hives, in the season of fruit-bloom, with their backs so covered with pollen from the flowers that they had the appearance of being a different race? Truly there are wonderful things in nature, and it seems as though no individual can fail to see the agency of a higher power in the design of these things. Verily, "All things work together for good to them that love God."

Elsie, Mich., Jan. 2. I. A. WOOLL,
Proprietor of the Oak Grove Fruit-Farm.

[Friend W., this is a matter that ought to be strongly emphasized and most emphatically taught. Right in sight of where I am writing is a strawberry-bed of strong, rank, thrifty plants. They are Bubachs; but there has not been a decent berry in the whole patch for two years, just because there are no perfect-flowering plants near them that they may be fertilized. They were red with berries, but they were all stunted, twisted, poor, insignificant specimens of strawberries. Now, my opinion is, that many of the poor, imperfect cherries, plums, apples, etc., that we see in various localities is because there are not bees enough kept to insure perfect fertilization. Market-gardeners have tested this matter so thoroughly that they now invariably keep one or more hives of bees in every greenhouse where they undertake to raise fruit, cucumbers, or any thing that requires the agency of the bees.]

ERNEST'S NOTES OF TRAVEL.

A VISIT WITH DR. C. C. MILLER.

After leaving the Dadants, Dr. Miller and I took the train for Marengo; and such a time as we did have visiting! On the sleeper that night we talked till the "wee sma' hours" of the morning; and after sleeping for two or three hours we again commenced it. We changed cars and then began to argue about some of the new fixings, and the probable outcome of thick top-bars, fixed distances, outside winter cases, and width of sections. Although I was very sleepy, Dr. Miller would, every once in a while, say, "Now, about that width of section. Are you sure that it would be wise to recommend to your trade $1\frac{7}{8}$ instead of $1\frac{15}{16}$ next year?"

I was *so* sleepy that I did not know what was wise, and, in fact, I did not care very much. I finally began to revive a little bit under the temporary stimulus of a good crisp apple which the senior Dadant handed me just before we left. Dr. M. would not eat between meals, but I felt a good deal better, whether it was in accordance with the laws of health or not. In response to his question I said, "Yes, sir; the trade demands a section a little less than a pound; and we, as supply-dealers, are obliged to cater to their demands, more or less. Besides," said I, "doctor, don't you see that with $1\frac{7}{8}$ sections you can use a follower and wedge in a super $12\frac{1}{8}$ wide inside? From what I saw in my trip in the East I am thoroughly satisfied that the sections wedged up in supers save a great deal of afterwork in scraping. All the 'big guns' in the East do it. Almost all L. supers are $12\frac{1}{8}$ wide, and in these you can not wedge up sections $1\frac{15}{16}$ thick with a follower and wedge."

The doctor nodded his head with a somewhat doubtful assent.

"But, see here, Ernest," said he, "do you think it is right or fair to sell a section, that weighs less than a pound, for a pound section?"

"No, I don't," I replied; "but sections are sold by the *piece* largely, nowadays."

So on we argued. I do not quite remember how we came out. Every once in a while our conversation broke off with, "Oh! by the way, Ernest, I want to know about those Hoffman frames;" or, "You haven't said yet how your bees are wintering in the cellar;" "Say, doctor, you did not tell me how your thick top-bars work, that you 'doctored' up with pieces of separator stuff."

Whenever friend M. cornered me in argument it was convenient to change the subject. So on we discussed persons and things until we reached Marengo. I had fixed out in my mind's eye that the town was so and so; but every thing was just the other end to. As we stepped off the train the doctor said, "Yes, there's Em with the horse."

Most of our readers know that "Em" is Dr. Miller's sister-in-law, the one who helps him in the bee-yard. Although I felt as if I knew her, of course I had to go through the formality of the usual introduction.

We drove for about half a mile, till we arrived at Dr. Miller's home. It is situated quite a little distance back from the street, upon a considerable knoll overlooking quite a stretch of country. The doctor had told me that I need not expect to see any thing very orderly; that his hives were such as nobody but himself would tolerate, etc. He evidently did not intend that I should raise my expectations very high.

Just as I alighted from the buggy I turned about, and there was his apiary, ready to go into the bee-cellar soon. This, if I remember correctly, comprised all of the home yard and a part of an out-apiary. The apiary looked very neat and orderly, and the hives—why, they did not look bad at all. It is true, they were not painted, and never have been. They had formerly been old ten-frame Langstroth portico hives. Gradually the doctor had imbibed the idea of eight instead of ten frames, like the rest of us. To make them eight-frame he pried off one side of the hive, cut off about two inches of the ends, replaced the side removed, and narrowed the cover of the bottom-board, and it was not such a very long job either.

The hives looked very much like ordinary Dovetailed hives without the dovetail. At the time of my visit, the bottom-boards had all been reversed, and screwed on upside down—that is, in such a way as to leave a two-inch space under the frames for winter. A large-mesh wire cloth was let down into perpendicular grooves in the bottom-board, closing the entrance to rats and mice while in the cellar. Bees, of course, could pass in and out.

While the doctor was putting up the horse I was thus engaged in the apiary. It was a little cold out, and so we went in to warm, where I had the pleasure of meeting Mrs. Miller. She, like her sister, is a true type of one of those whole-souled, kindly-faced Scotch women whom it is a genuine pleasure to meet. Both of the women-folks know how to handle bees, and Dr. Miller asks for no better assistants in his yards.

DR. MILLER'S BEE-SHOP AND HONEY-HOUSE.

If there is any thing that gives a fair index to a bee-keeper's notions, and of his methods of work, it is his workshop, or, rather, its contents. Over in one corner you will find things that he has tested and found wanting. And then, there are other conveniences that he could not dispense with. Over on that shelf maybe something new under the sun, for which he has very great hope. Perhaps the shop is orderly, and perhaps it is full of useless truck.

Now, I had expected to find Dr. Miller's shop a model of—disorder, and perhaps my expectations *might* have been realized; but it so happened that the women-folks have a hand in the work in the shop, and the doctor says it is "real handy" to have them around to straighten things up once in a while. Why, no, his shop was very orderly. He did not have a lot of expensive tools, but I noticed that he had good hammers, good saws, and a good assortment of nails arranged in very convenient boxes. These boxes the doctor has promised to describe, and his description will appear in a forthcoming issue soon.

We fell to arguing on the subject of T supers versus wide frames. He is still very much pleased with T supers; and the more he uses them, the more he seems to like them. But then, he says he does not know when he will cast them aside for something better. Of course, I argued for the topless wide frame; viz., the section-holder.

"Why," said I, "it protects three sides of the sections from the travel of the bees. I always noticed that the exposed surfaces of sections become a little bit yellow in time. If honey is coming in rapidly, and the sections are removed as soon as capped over, this yellow soiling is not so apparent."

The doctor insisted that it was not so bad but that his customers would tolerate it, and, besides, he could secure a crop of honey in T supers with less work. He had tried a few section-holders, and did not like them; and in evidence he showed me a few of them that I had sent him to be tried.

We pulled over several piles of T supers. In all, I noticed the bees had chinked in considerable propolis between the *edges* of the sections.

"Now, doctor," said I, "I want you to try wedging them up tight another year, and see if you do not save time in scraping propolis off. By the way, doctor, did you use those thick top-bars I sent you?"

"You sent them too late," said he, "and I hadn't time to put them in the hives then."

"Yes, I remember we were very much behindhand, and could scarcely fill our regular orders."

"I will show you the top-bars that I reinforced with separator stuff later, in the apiary."

Then the doctor showed me his double-tier shipping-cases. He used thin veneer boards between the two tiers of sections. This virtually made two single-tier cases, and at quite a saving in expense. Two strips of glass are used to display each tier. Turning from this we went upstairs.

"What does all this mean over in this bin?" said I.

"That is where we put our cast-away Clark smokers."

"That looks bad," I said. "Either you are very hard on smokers or else the Clark smoker is a very poor one."

Picking one up I observed that it had the old-style small blast-tube.

"Yes," said the doctor, "they are the old style of smokers. They did not last very long, and it was cheaper to get new ones rather than to fix the old ones up. Your new smokers, with large blast-tubes, are a very great improvement, and they stand hard usage in the apiary well."

"Do you use them in preference to the Bingham?"

"Yes, on some accounts we like them better. Em is partial to them because she can blow smoke with them at a long range, and she can force it clear through the tall piles of supers on account of the strong blast."

The doctor showed me an improvement, which he had made. With a wire nail he had punched 25 or 30 small holes in the sliding fire-door of the smoker, and said sliding door was made to shut tight so the sparks could not drop out. The rear draft has to pass through the aforesaid perforated holes, and these are too small to drop fire. This made the smoker almost faultless. The improvement pleased me so well that I said we would put it on our new smokers.

"What is that hanging up against the ceiling?" said I.

"That is a foundation-fastener that somebody kindly sent me. I do not know that I shall ever use it."

There were other things that had been sent him in the same way, and which he had neither the inclination nor time to try. Among them were some things that I had sent.

We then went out into the apiary. As usual, on the matter of covers we could not agree. Dr. M. wanted his cleats nailed without grooving on the cover-board, and he did not want the cover itself to stick over the hive. I insisted that a board is less liable to warp if let into a groove. Besides, in making hives in large quantities, these grooves are an easy thing to make. Some of the doctor's covers, I noticed, were a little warped, but then they had been long in use.

"But there is one thing I must have," said he, "and that is end cleats on the hives for handling them. Your handholes are hardly sufficient."

"But those cleats stick out in the way, and are an extra expense," I urged; "and if you would once get used to handholes I think you would like them."

"But, see here," he said; "in carrying hives into the cellar, all I have to do is to catch an endless rope over the ends of the cleats, and, with an assistant, the hives are easily picked up and carried into the cellar; and, when set in their places, the rope is easily removed. Your wire bails can't be disengaged so easily."

"Oh, yes!" said I, forgetting all about the handholes, "let me be your assistant in this job."

Dr. Miller went down into the cellar and produced a large soft rope. Lest some of our readers have forgotten how he picks up his hives and carries them into the cellar, I will here reproduce the engraving we made a year or so ago.

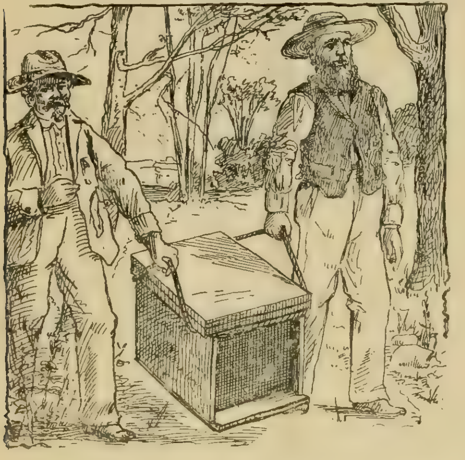
He quickly slipped the rope over one of the ends of a hive, and "There," said he, "get hold of the other side."

I did so. It was certainly very handy. We carried in a few colonies, and put them in the cellar.

"That's fun," said I, "but don't you like those bails which I sent you, for lifting up bottom-board and all?"

"No, I don't think they are nearly as convenient."

"And now," said I, "if I could have you at Medina, as you have me here at Marengo, I believe I could make you think they are at least good, but perhaps not quite equal to your ropes, with cleats on the ends of the hives to carry."



DR. MILLER'S METHOD OF CARRYING HIVES INTO THE CELLAR.

He has two bee-cellars—one under the house, and one under his workshop. Both are good-sized—about 15x15x7 feet, each capable of holding from 150 to 200 colonies, I should think. Neither was grouted, and the bottom was simply pounded clay. It had a hard dry surface, and could easily be swept. The walls had just been whitewashed—not so much for appearance' sake as for a purifier. It is well known, that whitewash is a purifier of walls. After a cellar has had bees in it over winter, it needs not only good airing but cleansing.

After we had stepped from the cellar I asked to see his thick top-bars. He did not know exactly where the hives were; but by a little hunting we found them. There was no burr-comb on top of them, and so far he regarded them as a success; but he was not so positive as I that they would take the place of honey-boards entirely. Dr. Miller, you know, is never positive about any thing. He is always open to conviction.

We then went into the house, for it was a little cold outside. After we sat down we talked queens. I was quite interested in his experiments in raising queens. He had not been successful with the Doolittle method, but Alley's plan had worked very nicely.

"Doolittle," I said, "makes it work to perfection. Why can't you?"

"I can not tell," said he; "and we were very careful to follow his instructions to the letter."

Dr. Miller now produced his record-book. His hives are all numbered, and each number corresponds to a space in the book. As we sat there that evening looking the book over, I was very much interested in reading over the memoranda of the several colonies.

Having been up late for several nights, I retired early. I spent a delightful Sabbath with Dr. Miller and his family, and had the pleasure of seeing him officiate as superintendent of their Sunday-school. The doctor is considerably interested in Sunday-school work. As most of our readers may know, who have attended conventions, he has a big talent "along that line."

To be continued.

THE WORLD'S COLUMBIAN EXHIBIT.

SUGGESTIONS IN REGARD TO THE APIARIAN DISPLAY, FROM DR. A. B. MASON.

Friend Root:—My "noddle" has done lots of thinking about the apiarian exhibit at the World's Columbian Exposition for 1893; and yesterday, Dec. 29, I thought of this plan for State work:

Let each State bee-keepers' society appoint a committee to look after the securing of an appropriation by the State legislatures or assemblies, for the making of a suitable exhibit. Also another committee to see that the honey, bees, beeswax, foundation, and every thing relating to our industry in their State, is collected and made ready for exhibition; also choose the best man or woman they may be able to secure, to go to Chicago and put every thing in the best possible shape and position for the best possible display, and look after the State's exhibit during the exposition, and then repack every thing and return to the owners.

"Now, this all looks easy enough on paper," some will say, "but how are we to be paid for our trouble and expense?"

Well, that is just what has bothered me, and is what I have been trying to "grasp by the horns." This very subject helped to get me 500 miles from home to attend the convention at Keokuk, in the hope that some one I might meet would solve the difficulty for me. Vain hope! No one I consulted knew more than I did about it. They were all like the mischievous boy John, in school. We have all heard of him, if we've not seen him. When the teacher asked Jim what he was doing, he replied, "nawthin'." The teacher then asked John what he was doing. The reply came promptly, "Helping Jim."

Till yesterday I've not been able to think of a plan, and found no one who could give me any "aid or comfort." I've thought over and over the offering of premiums in some shape, but nothing satisfactory presented itself. With the premium plan, somebody (and probably several somebodies) would "get left." By the plan I suggest, each would get just the amount he will be entitled to.

The plan is this: Let each one who is willing to help make his own State exhibit what it ought to be, notify the committee above spoken of as to what and how much he will exhibit, making an itemized bill of what he is willing to furnish. For example, some one says, "I will furnish –

500 lbs. comb honey (basswood) in 1-lb. sections, 25c per lb., 100 lbs.	$18 00
100 lbs. comb honey (buckwheat) in 1-lb. sections.	
500 lbs. extracted honey (white-clover) in 2-lb. Muth honey-jars; single, 35c; dozen	3 75
1 straw bee-hive, 50 years old.	
1 smoker (Bingham's)	1 75
1 colony bees (Italian) in Langstroth portico hive	8 00
1 colony bees (Carniolans) in Simplicity hive	6 00

Every package, or article of every kind, to be *distinctly* marked with the owner's name and postoffice; and if for sale, have the price also marked on it. Then let the committee say what they think best to have placed on exhibition, and then the owner can prepare and ship all to Chicago, with all charges paid, directed to the party having charge of the arranging and caring for the exhibit.

The reason I suggest that the committee say what should be sent is this: Perhaps ten or twenty might be willing to send one or more bee-hives, colonies of bees, etc., when but one of a kind would be needed; but the more honey and beeswax sent, the better.

Now for the most important part—the *pay* for all this work, risk, and expense.

From the amount appropriated by the State, pay all expenses incurred at Chicago, including the pay of the party having charge of the exhibit, unless otherwise provided for by the State. Then divide the remainder among the exhibitors according to what they have on exhibition, so that one exhibiting a colony of bees or a crate of honey or other articles, will get the share to which he may be entitled.

A person sending 2000 lbs. of honey would be entitled to twice as much pay as one sending 1000 lbs., provided other things are equal; for certainly no reasonable person who sends a thousand pounds in tin cans could expect as much pay as one who sends the same amount nicely put up in glass receptacles of different styles. But there are unreasonable people in all pursuits, and ours is not an exception.

When the exposition is over, the person in charge should repack, without charge, and return to the owners every thing not sold.

With such an arrangement, all things would be in common for the display from each State. The honey belonging to A, B, and C, would be used just as though it all came from one person, so as to make the best possible display; and each package being marked with the owner's name would tell to whom it belonged.

It is more than probable that parties placed in charge of some of the State exhibits will know but little about arranging things so as to make the best display, and perhaps have less taste than knowledge. In such cases, some one who *has* the taste will have to be hired to do the arranging.

Perhaps the next N. A. B. K. A. meeting will formulate some plan for general adoption; but in the mean time, working and planning should go forward. A. B. MASON.

Auburndale, O., Jan., 1891.

LATER.

The secretaries of some of the State bee-keepers' societies have written me for suggestions to be submitted to their societies at their coming conventions; and yesterday, Jan. 5, I answered three of them, giving the above plan in brief, because their societies meet before this will appear in GLEANINGS.

Since writing the above I have attended the Michigan State bee-keepers' convention at Detroit, and suggested the above plan to them, and they have started "the ball rolling," and appointed the needed committees.

Another suggestion might perhaps not be out of place. Some States have no bee-keepers' societies to organize the work. Would it not be a good plan for the leading bee-keepers of such States to get together and organize, or, by correspondence, agree upon some plan, and appoint suitable persons to look after the needed legislation and appropriation, and for doing all other needed work? for if this matter is left over till next winter it may be too late.

A. B. M.

MAKING SINGLE-WALLED HIVES OUTDOOR WINTER HIVES

BY THE USE OF BUILDING-PAPER.

Apropos of the discussion concerning double or single walled hives, I suggest a simple, inexpensive, and practical plan for the construction of hives.

Tack one or two thicknesses of building paper all around the inside of the hives, which is to be kept in place by tacking on narrow strips of wood or tin. Put a layer or two on the bottom-board, and over that nail half-inch lumber the size of your bottom-board. It will cost but 15 or 20 cents extra. To prepare your bees for winter, all that is necessary is to put on the upper story, place over the brood-frames some cobs or a Hill device; fill a small gunny sack with leaves, press it down tightly so as to prevent heat escaping upward, and your bees are in the best possible shape for outdoor wintering. The sacks can be stored in a dry place when not in use, and used for years without replenishing. I have found that there is no necessity whatever for dead-air spaces and great bunglesome hives. This I have demonstrated by actual experiment. Paper is a non-conductor of heat and cold. Wrap your feet in a piece of strong paper, and you can ride all day in the coldest weather with warm feet. Put a newspaper around your body and you can withstand the most intense cold. I put paper covering over my bees to keep them warm till I put them in the cellar, and for a number of seasons I did not remove it until I placed them on the summer stands. A. C. TYRREL.

Madison, Neb., Jan., 1891.

[Very possibly the building-paper will answer. If you mean tarred paper, it would be rather distasteful to the bees. Paper itself is very warm; and when Mr. Danzenbaker was here a year ago he was continually advocating layers of paper instead of chaff packing. He argued that it was just exactly as good, and a great deal cheaper. It is hard to say just yet what will answer for our northern localities; but enough has been suggested to set us to experimenting in earnest.]

[In addition to what Ernest has said, I will say that paper lining for hives is a very old idea, and has been taken up and dropped several times within the last 25 years. One great objection is, that it gets damp and wet. The hives become soggy, and they can not be dried out as can a chaff-packed hive. I should like to have Doolittle and others, who once used paper, to tell us why they gave it up. Our house-apiary was made with several thicknesses of building-paper, with air-spaces between them; and although it is above ground, it is a cold, damp, soggy structure, even in the summer time. Perhaps a very loose, porous paper might be found that could be put on in such a way as to let it dry out as chaff does.]

FORETELLING THE WEATHER, ETC.

POPULAR SUPERSTITIONS.

Mr. S. Morrett, Akron, Ind., wishes me to answer through GLEANINGS the following questions:

1. "Would killing chickens by a mink make them in any way unfit for table use?"

I see no possible reason why it should.

2. "Do any of our animals, like the insects or higher animals, by their preparation for winter or otherwise, show that they are in some way forewarned as to whether the winter will be severe or mild?"

I have no idea that there is a grain of truth in such views, although I know that they are current among many, especially of the last generation. The same people plant in the moon, think fireweed grows spontaneously, that chess turns to wheat, and that patent medicines have startling virtues. I believe a better education dispels such views.

3. "Many claim, that, when the muskrat

builds high, there will be severe winter or high water."

Very likely; this is just as likely to occur as though the little rodent built low. Happily the muskrat does not make the weather.

4. "Some bee-keepers say, if the drones are killed early, the winter will be severe, and vice versa. Is there any truth in it?"

The past season, drones were killed in early summer, and yet the weather is and has been remarkably mild. The same was true a year ago. The weather at the time, in affecting the harvest, leads to this premature destruction. There is, however, no possible relation between such events and the future. When men knew little of nature they were ripe for such superstitions. With the development of science, such beliefs will become wholly a thing of the past. A. J. COOK.

Agricultural College, Mich., Jan. 3.

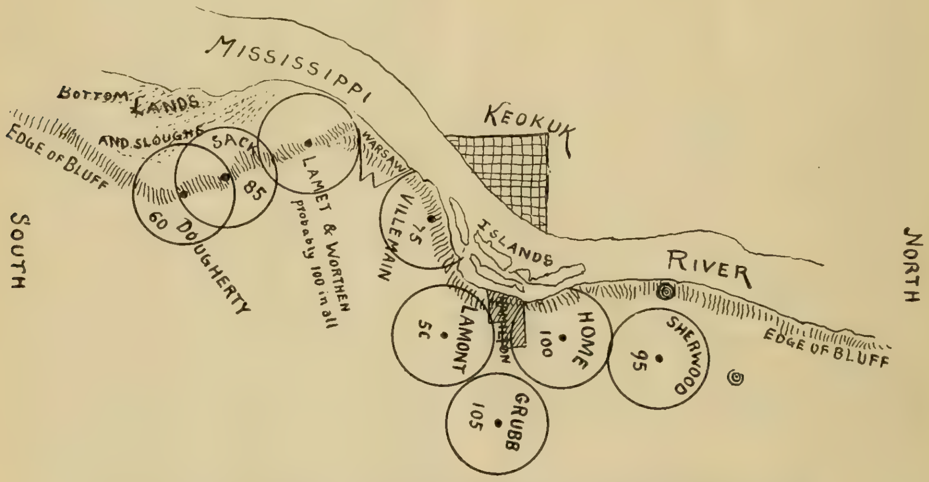
[I want to say amen to Prof. Cook's replies. Our nation is full of rural people, especially those well along in years, who insist that animals have foreknowledge of the weather; and the amount of time spent watching these senseless movements, if turned in the line of scientific investigation, would enrich the world. Let us do away with superstition, and turn our brains to the solution of real problems.]

ARRANGEMENT OF OUT-APIARIES.

DADANT'S SYSTEM ALONG THE MISSISSIPPI RIVER.

Friend Root:—The very interesting article of Mr. France, on out-apiaries, page 883, has induced us to give you our own experience in this matter, not because we can throw any more light on the question, but because our practice, which extends back to 1871, in the matter of out-apiaries, confirms the views of both Mr. France and Dr. Miller, and will add weight to their statements.

Under ordinary circumstances it is not advisable to place apiaries nearer than four miles apart; but Dr. Miller is undoubtedly right when he says that the configuration of the land has a great deal to do with the greater or lesser distance that the bees will travel in certain directions.



THE DADANT SYSTEM OF OUT-APIARIES ALONG THE MISSISSIPPI RIVER.

In the accompanying diagram you will perceive that these apiaries are all located on land sloping toward the Mississippi River, and are separated from one another by creeks and groves of timber land. The Grubb apiary is owned by D. W. McDaniel, who has had charge of our apiaries also for a few years past. Of all these apiaries, the Sherwood is the best in the product of both spring and fall crops, although there are seasons like the past when the fall crop fails there altogether.

The Villemain apiary has the poorest location, to all appearances; but it is located near the only basswood grove there is in the country, and has also quite a fall pasture from blossoms that grow on the islands near it. But what will you think of the Sack apiary, which is located a little over two miles south of the Lamet apiary, with another apiary close to the latter, and not shown on the diagram, and only one mile and a quarter north of another apiary of 60 colonies, owned by A. Dougherty? Yet this Sack apiary gives us the best average of honey of all, excepting the Sherwood apiary. The reason of it is, that the pasturage is all west of it on the river bottoms, and very abundant. It is probable that the bees in this apiary go as far west as the river, about three miles, while they perhaps do not travel over a mile east on the bluffs. Their course north and south, in the direction of those other apiaries, is over a hilly country covered more or less with timber, which makes their flight more difficult.

The two small circles in the north part of the diagram show spots on which we have had apiaries formerly, and which, you will perceive, were further away from home than the present. At that time the Sherwood apiary did not exist, nor did the Grubb apiary; and yet we must say that we can see no difference in the yield of the home apiary. We are satisfied that the Grubb bees go east, the Sherwood bees and the home bees northeast, for their crop. When we say the bees go in a certain direction, we do not mean *all* the bees, but the greater part of them. We can give you one convincing instance of the correctness of this opinion.

By glancing at the diagram you will notice that the home apiary is just about a mile and a half from the north point of an island in the river. In certain seasons these islands are covered with water in June; and after the waters recede they become covered with a luxuriant vegetation, and the yield of honey from them is very large. In one of these seasons we found a colony, belonging to a neighbor, located half way between us and the river, harvesting a large yield of honey from this source, while our bees harvested nothing. Is it not evident that our bees had not gone that far? Yet we have seen them two miles and more from home in another direction.

Had we kept as careful records as Mr. France did, we should probably also be able to derive some good lessons from these records; but we are sorry to say, that, although we have harvested enormous crops of honey from our bees, we have been rather careless about keeping a record. If we had things exactly as we ought to have them, in the matter of location, we should spread all the upland apiaries a little more, and place them, say four or five miles apart; but there are lands like those Mississippi bottom-lands which can support apiaries very close to one another, and make money for their owners. C. P. DADANT.

Hamilton, Ill., Dec. 23.

[Thanks. These drawings are exceedingly helpful and valuable. The Sack apiary, in the diagram, is a remarkable illustration of the fact that the lay of the land has sometimes a decided influence upon the bee forage, and that we can not always lay down rules that an apiary should be just exactly three or four miles from each other in all cases. These exceptions are interesting, and there is no way that we can decide where we can locate apiaries profitably except by trial. Of course, we can be guided to a large extent by swamps, ranges of hills, proximity to water, etc. You do not give the size of the circles in miles; but from reading your description I can gather pretty nearly that they are about 2½ miles in diameter. From this the reader can gauge pretty fairly the relative distances. A great many interesting facts are being developed. A. E. Manum has sent in a diagram which we will present to our readers in the next issue.]

THE MICHIGAN STATE CONVENTION AT DETROIT.

HELD JAN. 1 AND 2.

While this convention was not largely attended, those present were perhaps among the best and brightest bee-keepers, not only to be found in Michigan, but I think they compared well in intelligence with any we have in the world. One who is accustomed to attend conventions will very readily pick out those who are in the habit of attending either bee-conventions or conventions of any kind. It seems to be something like this:

The man who has never attended conventions, or who has not done so for a great while, is the more apt to be hasty in coming to conclusions. He is also, as a rule, more ready to think evil. He imagines that the world is full of corruption, and that even bee-keepers are more intent on finding a chance to steal and not get caught than they are to find some way whereby they can be helpful to their fellow-men. The worthy president, Prof. Cook, has, perhaps, done much to bring about this better state of affairs. How natural it sounds, to hear him say, when some absent member is violently attacked, "Oh, no, my friend! If you knew the brother as well as I do, you would not think of charging him with such a thing."

Sometimes, it is true, he is obliged to admit that some brother has done a very foolish and possibly a very wicked thing. In such a case he reproves the guilty one in such a gentle, kindly way, and in a way that stirs him to a tremendous resolution to do better next time, that the spirit is really contagious. Please do not imagine that he ignores and smooths over all the wrongs that exist in society, or in bee culture, if you choose. He will sometimes speak right out in the convention, something like this:

"Now, Bro. ———, since this matter has come up right before us as it has to-day, will you just let me say that I have felt greatly pained, many times, to see you go to such extremes in this direction? Here are all these good friends of yours who disagree with you. Now, will you not, for their sakes, and out of respect to their opinions, withdraw a little from your vehement views, or, at least, put it a *little* milder?"

The kindly look in his face, at the time he speaks, prevents anybody from taking offense; and, in fact, jangles or hard words at bee-conventions are unknown when Prof. Cook is present. During our last convention we discussed many matters where there was pretty strong disagreement; but it was from first to last characterized by a spirit of brotherly love that I am sure every one of us carried home; and I feel, too, that its influence is going to make us better men for a *long time* to come.

DOES IT PAY TO USE SUCH LARGE QUANTITIES OF COMB FOUNDATION?

You will remember that this subject has been up in the bee-journals, and there has been some intimation that editors interested in the sale of the article may, at least unwittingly, have kept purchasers in the dark. Our good friend R. L. Taylor was called upon to open the subject; and by some means it fell upon myself to ask him some questions. I was somewhat surprised, and a good deal amused, to hear him insist so emphatically that we can not afford to have combs built without foundation. He said that, inasmuch as combs would last us a great number of years, the *first cost* is but a small consideration. He would have the sheets fill the frames. When it came to a rising vote, the bee-keepers were almost unanimous in indorsing his view. Foundation for section boxes brought forth much the same decision.

The number present who had out-apiaries showed very conclusively that there is a wide difference in the honey-yield in localities only two or three miles distant. A man may have a good yield of honey, while his neighbor three miles away gets almost nothing. This indicates the importance of testing different points in your locality, say three or four miles away. When you strike a point where bees seem to do best, gradually increase the number of colonies until you ascertain how many can be profitably located at a certain point. This will also help us to avoid the disaster of bad seasons. It is a little on the plan of not putting *all* your eggs in one basket.

ADULTERATED LIQUID HONEY.

It is a sad fact, that there is once more considerable spurious honey offered for sale. Samples were on the table, brought from some of the Detroit groceries. One could readily judge by the taste that both cane sugar and glucose were used in getting up the mixture. It was labeled "Michigan Honey," but, of course, the name and address of the party putting it up were not to be found on the label. This alone is a plain violation of the laws of the State of Michigan; and some of us were vehement in demanding that the guilty parties be prosecuted at once. As friend Taylor, however, sat in a thoughtful attitude with his head down upon his hands, I suggested that we hear from him.

As he did not seem inclined to say any thing, we bantered him somewhat; and in response to a question of mine he said he would cheerfully answer any questions I might wish to ask. Now, as there is much wisdom in his reply, especially as he is a lawyer of experience, and a member of the State Legislature, I will try to give his replies here.

"Friend Taylor, have we not ample proof right here before us, so that it will be an easy matter to bring these guilty parties to justice?"

"Well, the proof is plain enough, friend Root; but I am sorry to say that it will not probably be an easy matter to deal with the offenders. They have plainly violated the laws of Michigan, it is true, in putting honey on the market without the name of the producer, providing we can *prove* that which we all *know* very well—that this honey is not the product of the bees. Unfortunately, our chemists are at fault. Our good worthy president, Prof. Cook, took some honey out of his own hives, at the college apiary, and sent it to Prof. Wiley, at Washington, who pronounced it, after a chemical analysis, *adulterated*."

This raised quite a buzz, and I guess there was some indignation in the buzz. I turned to Prof. Cook, and asked him if it was the same Wiley who started the story about manufactured comb honey. He assented, and then *I* commenced to boil over. Now, here is a sample of Prof. Cook's gentleness, and, I think I may say, wisdom. He replied something as follows:

"Friend Root, Prof. Wiley *has* made some mistakes. It is true, he did pronounce the honey impure that I took from my own hives; but before we condemn him too severely, let us remember that the best chemists we have in the country have made the same blunder. Perhaps we had better acknowledge that chemistry is not to be trusted with absolute certainty at the present time, between manufactured glucose and the glucose, or grape sugar, that is found in flowers. Before we condemn friend Wiley too severely, let us bear in mind that he is an excellent man, and one who has done excellent service in many departments of science for our country."

Friend Taylor added further, that he presumed if we, as a body of bee-keepers, were to take oath that, according to the best of our knowledge and belief, the samples of honey before us were composed largely of cane sugar and glucose, something might be done. The offenders, however, were said to be a rich manufacturing institution, who put up pickles, jellies, and other things, in glass tumblers. One man would stand a rather poor chance in opposing them; and I believe our best advisers incline to the idea that the Bee-keepers' Union had best take the matter in hand.

I tell you, friends, the great reforms of the present day are conducted by those who work slowly and carefully. Instead of boiling over, and condemning those who have capital, as a whole, shall we not bottle our indignation for the present, and —— send Bro. Newman a dollar to make us a member of the Bee-keepers' Union, and let *him* manage these matters?

Now I fear I must direct you to other bee-journals for fuller reports of the proceedings of this convention. For the present I want to tell you about my visit to

D. M. FERRY & CO.'S GREAT SEEDHOUSE, DETROIT, MICH.

I started to get up as usual, somewhere about six o'clock. Somebody in the next room called out to know whether myself and friend Hilton (my room-mate) were starting out for greenhouses. I answered eagerly, "Why, to be sure, we are. Get on your duds quick, and go with us."

"But, may be when you find out who it is you won't want him along."

"Yes, I do want you to go along. There is not anybody in the world, who wants to go, whom I do *not* want to go along."

After I had said this I began wondering whether I told the truth. Oh how glad I felt, as I searched my heart, that I had told the full plain truth! If I *have* an enemy in the world, he is just the man I should like to take by the hand and show him the greenhouses in the early morning. (Yes, I should rejoice to take, on such a trip, even our poor mistaken friend Hill, of the *Bee-keepers' Guide*, who has labored so long and hard to hold up before the world both my fancied and real weaknesses and imperfections.) I thought the voices in the next room sounded somewhat familiar, but I could not quite make them out, and they had a good deal of merriment at my expense. Well, they were no other than two of my best friends, M. H. Hunt and R. F. Holtermann. It was friend Hunt who suggested going to Ferry's new seedhouse instead of to the greenhouses. I owe him a big debt of gratitude for a lot of other similar deeds of kindness.

This wonderful structure has been built only about two years, on the site of the one previously burned. It is 300 feet long and 120 feet wide, and has between *seven and eight acres* of floor space. Now, when I tell you that it is seven stories high, and every floor occupied, you may wonder as I did, that so little has been said about such a tremendous enterprise. Like our own establishment, this one is, a great part of it, in charge of women. A woman gave us a permit to go through the rooms. Crowds of bright, intelligent-looking women, passed up the stairs with us, put their cloaks and hats nicely away in cupboards made especially for them (a separate cupboard for each cloak), and then took their places in the handsome offices that filled a part of one of the great rooms. These offices are finished off in the handsomest style of present office architecture, and it was a great study for me. Decorated wire cloth separates the clerks from each other, so each one has really a little room of his own, as it were, where they can not be annoyed by visitors or by each other. The bins, drawers, pigeon-holes, and other arrangements for the rapid classifying and mailing of seeds, showed wonderful skill and ingenuity; and, further on, the rapid movements of the girls as they took up their work put to shame any sleight-of-hand performance I ever saw. One of the girls worked so rapidly in pasting up packets of the seeds that I asked her to please go slow enough so I could see what she was doing. She smiled as she did so. The paste they use is about the consistency of butter, only not quite the color. A little bit is taken on the end of the finger. In their rapid movements this finger is stuck straight out when not needed, so as to be out of the way; and one is astonished to see that the paste gets just where it is wanted, and nowhere else. At another table dozens of girls were dipping up seeds with teaspoons, and putting them into the open mouths of printed packets. It looked for all the world like feeding ducks with a spoon. Each duck, however, got only one spoonful. A man sat at a raised desk in the center of the room. By the way, where there are so many hundreds of young people, it is not any wonder that an elderly one is needed for a boss. A good many of the young eyes sparkled with fun and mischief, especially if they could catch sight of any glimpse of a smile lurking around the corners of the mouths of the visitors. And I tell you, there does not want to be very much fun or "cutting up" when you are putting up seeds. Remember what I said about 20 cents' worth of cabbage seed, on another page. There are between 800 and 900 people employed in this one building. They have the same Grinnell system of sprinklers we have. The rooms are warmed by steam, as ours are, and lighted by 1000 incandescent lamps. Surplus seeds are stacked, tons upon tons, in bags piled up in neat square tidy piles. I wondered whether rats and mice ever found a harboring-place in this immense institution. My keen olfactories did not advise me of the proximity of any of these mischievous rodents.

Ferry's specialty is, as you may know, furnishing the groceries and country stores of the United States, and perhaps the world, with garden-seeds. In order to do this the boxes are sent out on commission, and called in before Jan. 1. Our visit was just in the nick of time. Their plan of giving their customers the best seeds is something like the one I have indicated elsewhere. Old seeds are not *always* inferior. But they protect their reputation by a careful testing, winter and summer. I was pleased to notice how they manage to keep their seed-cases clean and bright, after taking their chances in transportation, and being kept during spring and summer in the average show window of the village store. Their boxes and cases are all dovetailed, like the Dovetailed hive. The bottoms are put on with a nailing-machine, or with screws. These latter are also driven home with machinery. All nails and screws are sunk below the surface of the wood; then when the box comes back it can be run through a suitable planer or sandpapering - machine, and made new all over quicker than you could wash it all off with brush and soapsuds. New labels are then put on; new seeds (or old ones that stood satisfactorily the test) are then put in new packets, and the cases filled up with such an assortment as the great world demands, and sent off to do duty. Now, do not find fault, or complain of sending seeds out on commission. If they did not do their business honestly and well, they would never have built up such an immense institution. If nearly 1000 are employed in this building, how many people do you suppose D. M. Ferry & Co. keep at work during the summer time? Here we have illustrated the wonderful way in which nice work and accurate work can be done at a comparatively small expense. Those girls could never acquire that wonderful swiftness did they not put up thousands upon thousands of packages; neither could the other enormous machinery of such a business be used with so little expense in any other way. I should like to tell you more, but space forbids, just at this time.

OUR QUESTION-BOX,

With Replies from our best Authorities on Bees.

QUESTION 176. *Do you think bee-keepers have secured any advantage from the Government Experiment Station? 2. Is it desirable to make any effort to induce the government to do any thing more for our industry?*

No.
Ohio. N. W. H. R. BOARDMAN.

1. Yes; every *little* helps. 2. Yes.
Vermont. N. W. A. E. MANUM.

1. Very little. 2. Remove the custom duty on beeswax.
Illinois. N. W. DADANT & SON.

No, not as a general thing. 2. The Lord helps those who help themselves.
Illinois. N. W. C. MRS. L. HARRISON.

1. Perhaps a little. 2. I think the advantages are not enough to make the effort desirable.
New York. C. G. M. DOOLITTLE.

I don't know what they have done or what they will be likely to do.
Wisconsin. S. W. E. FRANCE.

I do not know of any important advantage gained. 2. Not until we clearly see some advantage ahead which the government could readily secure for us.
Ohio. N. W. E. E. HASTY.

I should suppose very little. Only one or two stations are doing any thing with bees, and two seasons are too few to secure any important results. Yes, every State should work to aid bee-keepers.
Michigan. C. A. J. COOK.

No. 2. Yes, I think it is. In Canada their societies have aid from government, and horticultural societies are helped by our State. Experiment stations are of immense value in other departments—why not in bee-keeping?
Illinois. N. C. C. MILLER.

Yes; the experiments to test whether bees will puncture sound grapes was a good move in the right direction, and ought to remove much prejudice. 2. Most certainly, get the government to do all it will for us. There is not much danger of our getting *too* much.
Wisconsin. S. W. S. I. FREEBORN.

Prof. Cook has been much more valuable to our specialty than the experimental station, but it was a good "backer." 2. Yes, if the work can be put in first-class hands. A thorough, practical, and scientific bee-keeper should have charge of such work.
Ohio. N. W. A. B. MASON.

Yes. The government analysis of honey shows us that some of the best chemists are not able to recognize pure honey. 2. If you have any surplus energy you want to work off, here is a chance. You will probably earn more than you get.
New York. C. P. H. ELWOOD.

I think not. 2. The less the government has to do with our industry, the better off we are. The more we induce, the more lies we stir up. Smart professors and clerks imagine wonderful things when bees are mentioned to them, and something funny must be said about the "busy bee." The government is doing very well by us now. Let us let well enough alone.
New York. E. RAMBLER.

I have not seen any yet; have you? 2. I think likely, if it were done in the right way, but I doubt whether it can be. The first thing the government will do will be to place it in the hands of somebody who does not know any thing about practical apiculture, and who, either through favoritism or ignorance, will place it in the hands of one just as ignorant as he is. That is all it will ever amount to, I guess.
Michigan. S. W. JAMES HEDDON.

Perhaps; as, for instance, from the report of experiments on bees vs. grapes. The position gives authority, in the minds of many people, to statements which, coming from a more careful experimenter in another position, would not have so much weight. They have also received harm from it, as, for instance, in the "sure cure" for foul brood emanating therefrom. 2. Yes, the right man might do a great deal of good.

Illinois. N. C. J. A. GREEN.

[I suppose the question has no reference to any reflection on our experiment stations that belong to the different States, for these have certainly given us some great helps; and I heartily indorse Prof. Cook's position, that every State should help its bee-keepers. I believe the Government Experiment Station will doubtless do much for all our industries.]

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

BUYING AND SELLING HONEY; GRADING A NECESSITY.

Allow me to extend my sympathy. Your troubles in regard to buying and selling honey are the common troubles of all bee-keepers. I would suggest, as a remedy, that all honey be graded as other products are; and I think that, if A. I. Root or some other prominent bee-keeper would bring it up at the convention at Albany, something could be done. I would suggest, as a starting-point, something like the following grades:

No. 1. Extra pure white, in No. 1 sections or cartons, no candied honey, capping free from stains.

No. 2. Pure white; slightly stained cappings should be admitted to this grade.

No. 3. Slightly shaded and stained honey not good enough for No. 1.

No. 4. Dark honey, partly filled sections, and badly stained.

No. 5. Leaky sections, wormy and broken.

Extracted honey could be graded in about the same way. These grades could be printed on slips; and bee-keepers could inclose one to their customers, when shipping, and so establish a uniform grade to buy and sell by.

Saratoga, Wis., Dec. 7. THOMAS ELLIOTT.

[You are right. If honey were properly and *honestly* graded and honestly named it would do away with half the trouble in buying and selling. When a buyer receives honey of a poorer quality than he *expected*, he has some grounds for complaints. Bee-keepers are disposed to be honest; but a little self-interest (the kind that puts the best out) sometimes slips in. Carelessness in grading, or, what is worse, no grading at all, meets its reward, and a mighty poor reward it is sometimes. Those producers, as, for instance, Manum, Crane, and a good many others, who grade their honey, get a good price.]

NAMELESS BEE-DISEASE NOT CURED BY REMOVAL OF THE QUEEN.

I agree with friend Doolittle, in what he states in GLEANINGS, Dec. 1, page 855, of the nameless disease. I have removed the queen several times through the summer, and it did no good. Those that were badly affected with it last summer, 1889, showed no signs of the disease after cold weather, nor did they show any signs of it until hot weather came in earnest; then the disease broke out again in some of those that were affected last year, but not all, but started in some healthy ones, and kept with them until freezing weather came; but I have not seen any signs of it since, although the bees have been flying freely. I believe yet, that honey taken by robber bees from colonies affected by said disease will carry it home, and soon it will break out in their hive. At any rate, it has with me. I expect to try taking all the combs of honey away from the colony so affected next year, and give them empty combs, and see if that will cure it. I have tried taking away queens, and failed nearly every time.

JOSIAH EASTBURN.

Fallsington, Pa., Dec. 22, 1890.

[Friend E., this matter came up at our recent Detroit convention. Almost every one present claimed that changing the queen was a perfect cure; and Prof. Cook said he had recommended this remedy to great numbers, and had never yet heard of a failure. If the disease you have is carried from one hive to another, as you describe, I think it must be something else.]

THE THEORY AND PRACTICE OF BOTTOM VENTILATION IN HIVES.

Will my bees winter in dry cellar with permanent bottom-boards on, with top ventilation? My bottoms are all fastened, and I have a gable roof with a ¾-inch hole at each end, with a piece of burlap over the brood-nest. I have only ten swarms. Why is it necessary to have the bottom open? HIRAM B. WINSLOW.

Mahopac, N. Y., Dec. 8.

[Your bees may winter with the top open, but the tendency of the times is emphatically against top ventilation of the hive in the cellar. It should come from the bottom, either through a good-sized entrance kept cleared of dead bees, or, better, from the whole lower part of the hive, the bottom-board being removed. The reason is this: If the top is open, all the heat rises and escapes. On the other hand, if the top is closed the heat rises and is confined near the top, and the surplus, if any, "overflows" at the bottom. Bees need plenty of ventilation in the hive, but they must not have it at the expense of heat.]

THOSE REGISTER-BOARDS OF MUTH-RASMUSSEN'S, AGAIN.

In your foot-note to my article, page 850, you propose printing numbers on the date-cards, running from 1 to 100. I must strongly object to this. How many bee-keepers have exactly 100 colonies? If one buys a package of 100 numbered date cards, but has less than that number of colonies, what is he going to do with the rest of the cards? Or if his number of colonies exceeds 100, what then? No; please leave the place for the number blank, and let the purchaser himself write the number as it may be wanted. Print the cards just as the sample, only *make the date figures as large as possible*, and I am sure it will be thus most satisfactory. The cards might be (for convenience) put up in bundles of 25, like postal cards. When you get them printed, send me 200 cards, without further order. As apiaries and millinery stores are not always close neighbors, I would suggest that you, for the accommodation of your customers, obtain and keep for sale suitable black pins for these cards.

WM. MUTH-RASMUSSEN.

Independence, Cal., Dec. 9.

MRS. L. HARRISON INDORSES THE STRAWBERRY-BOOK.

I was slightly ill of late; and, casting about for something to alleviate my aches and pains, my eye fell upon your strawberry-book; presto! they were soon forgotten. How I dug, raked, and planted, and delighted in seeing them bud and blossom, and gathered the luscious fruit! It is a grand panacea for an invalid. Let him have a small strawberry-bed, and he will soon take a new lease of life. If he can not walk, roll him out in a wheel-chair and put a light tool in his hands. If he can not dig and plant, do this for him, and let him cultivate them. The blood will soon be bounding through his veins, and he will be a boy again.

Peoria, Ill., Dec. 5. Mrs. L. Harrison.

OUR HOMES.

But one thing is needful; and Mary hath chosen that good part, which shall not be taken away from her.—Luke 10:42.

Bunyan, in the Pilgrim's Progress, gives us a picture which he calls "The Man with the Muck-rake." A poor, needy old man, poorly clothed, and bent with age, stands stooping over with a poor, miserable, rickety rake, with which he continues to pull up toward him the straws and the leaves, and the dust and the rubbish; and while he is thus busily engaged, an angel of light holds above his head a celestial crown. The old man, however, is too busy with his sticks and straws to pay any attention to the celestial crown; in fact, he won't even look up toward it. He is too busy. The straws and the sticks, the dust and the rubbish, are of too much importance, in his poor feeble judgment, to take the time to cast even one glimpse toward the crown of gold. The angel even tries to make a trade with the poor old man, and offers to swap the crown of gold, "even up," for the poor, miserable, dilapidated old rake. But the man stubbornly refuses to trade. Did you ever think, my friend, what a wonderful illustration that is? I hardly need tell you that the man with the muck-rake is ourselves—you and I—and our neighbors. Bunyan, by his figure, means to remind us that there is a shining crown just above our heads, and that it is held there by an angel of light. This angel is pleading for attention. He is calling us to look up from our busy cares, and to see the golden crown. I wish I could look into the faces of the readers of Gleanings this new year, and see how they receive the picture I have tried to place before them. Some of them, I know, will say it is true; others will admit that it is a very pretty fable, but will rather conclude that it is *mostly* fable. Still others, who are dissatisfied and disgusted with the straws and leaves—yes, and perhaps with the miserable old muck-rake too—will admit the fore part of the illustration, but will deny that there is a crown—a celestial crown, for each one of us; and I am afraid that we are all, in fact, more or less lacking in faith in regard to the crown of glory that awaits us. The question is, "Is Bunyan's figure a truthful one?" Is it too extravagant? Is it real? Let us turn to God's holy word, and see what authority good old John Bunyan had for his wonderful figure. He was a student of the Bible, and his wonderful illustrations came right home from the Bible itself. In fact, he had nothing to work with except the word of God, and the inspiration of God's Holy Spirit. May that Holy Spirit be with you, friends, in my talk to you this morning, and enable me to unfold the Bible promises in this very line.

We will first turn to Proverbs, fourth chapter, where it speaks of Wisdom. We read: "She shall give to thy head an ornament of grace; a *crown of glory* shall she deliver to thee." These are the words of Solomon. He knew what it was to wear a crown. He had wisdom beyond the average of humanity, and he says that this wisdom shall give us an ornament of grace—an ornament for the head, mind you. We like to see grand men and beautiful women. It is the duty of all of us to look well before our friends. Our wives and daughters give considerable attention to ornaments, especially for the head; and they do well, providing they forget not this ornament of grace which Wisdom gives. Wisdom is used in the Bible sense as the opposite of folly. One who listens to Satan, and gives way to temptation, has forgotten wisdom. Wisdom directs us to be pure in heart; and it also directs us to seek first the kingdom of God and his righteousness, and promises that the sticks and straws, and the things that we need, shall be added; and the Bible promise goes further, and says, "A crown of glory shall she deliver unto thee."

Let us now turn to first Corinthians, 9th chapter. Paul, in exhorting us to godliness, uses the figure of the races, and says, "Know ye not that they which run in a race run all? but one receiveth the prize." You see, they had prizes in those days, as they do now. In their contests of skill and physical strength, but one received the prize. It is not so in God's service, however. There are crowns enough for all, and there is no partiality and no respecting of persons. Paul continues: "So run that ye may obtain; and every man that striveth for the mastery is temperate in all things." In those days, as well as now, they had discovered that a man must be temperate to obtain a prize in a physical contest. No drinking man can expect to excel. Now comes the point of our lesson:

"Now, they do it to obtain a *corruptible* crown; but we an *incorruptible*." Paul tells us that the crown held out to us by the angel of light is an incorruptible one, "which fadeth not away."

Let us now turn to James, first chapter. We read: "Blessed is the man that endureth temptation; for when he is tried, he shall receive a crown of life, which the Lord hath promised to them that love him." Bunyan calls it a celestial crown. In the text above it is called a crown of life. It also tells us that it is given to the one that endureth temptation; and it comes, too, when he is tried. We sometimes think it is hard to meet trials. Some of us have prayed, perhaps, that God would remove these temptations that beset us and pester us continually. Our last text, however, seems to indicate that it is a good thing to be tested and tried. In fact, we could not have a crown of life otherwise. I sometimes think that it can not be possible that others are called upon to meet temptation so continually as I am. As I look out upon the world, it seems to me that nobody ever had such terribly hard work in trying to be good as I have had. I once heard a minister of the gospel say in his sermon that Satan himself, the *prince* of the powers of darkness, could be in only one place at the same time. I was tempted to question this theology. Very likely the preacher gave it as his own opinion, in an off-hand sort of way. Why could I not accept such a doctrine? Well, it did not seem to be possible that the prince of evil should leave all mankind, and turn so much of his attention to my poor self; and then came a helping thought: If it were true, I might feel glad that the rest of humanity had a respite a good deal of the time.

I used to think that Revelation was a dry book; but of late I have learned to turn to it and get much comfort and consolation. Especially do I like that second chapter that has so many promises to him that overcometh. For instance: "He that overcometh and keepeth my works to the end, to him will I give power over the nations." And again: "To him that overcometh will I give to eat of the hidden manna, and I will give him a white stone, and in the stone a new name written which no man knoweth save him that receiveth it." Well, in that same chapter, about the middle, we read: "Be thou faithful unto death, and I will give thee a crown of life." You see this crown is promised to those who are faithful. It is not enough that we be faithful a little while; we want to be faithful unto death, and then have we the promise of a crown of life. Did our friend Bunyan put it too strongly? Let us turn to First Peter, fifth chapter: "'And when the chief Shepherd shall appear, ye shall receive a crown of glory that fadeth not away." By reading the first part of the chapter we find this wonderful promise is to those who "feed the flock of God, not by constraint, but willingly; not for filthy lucre, but of a ready mind." The promise of a crown of glory is to those who are trying to make the world better; who "rejoice not in iniquity;" who "think no evil." Further along we read, "Be sober; be vigilant; for your adversary the Devil as a roaring lion walketh about, seeking whom he may devour."

The "adversary" will most surely entrap you into wasting the precious moments in fussing with straws, leaves, and the dust of the earth, if he can do so. He will leave no stone unturned in his schemes to get you to look *down* and not *up*, if it can be done. If your face, like that of the man in the fable, looks constantly downward toward the earth, you will never see the shining crown nor hear the angel voices.

Now, my friends, during this coming new year let us see to it that we look out for him who comes "as a roaring lion." Did you ever feel yourself in a bright, cheerful mood, ready to work for the good of humanity, ready to listen for the angel voices, when all of a sudden something drove out the good spirit and pulled you down to earth? Perhaps it was some little trouble with a neighbor. May be he borrowed something and did not return it. May be he showed a greedy, overbearing, and unfeeling spirit. Away go thoughts of union meetings, good resolutions to keep bright and hopeful, and, before you know it, you are led away, down amid the rubbish once more. I know what it is, dear friends. I have wondered whether there were anybody else who felt the truth of two lines in one of good old Dr. Watts' hymns as I have felt them—

Prone to wander—Lord, I feel it;
Prone to leave the Lord I love.

At such a time it does me good to repeat mentally, "Wherefore do you spend money for that which is not bread, and your labor for that which satisfieth not?" I say to myself, "Well, how is it, old fellow? Is this thing that is just now stirring you up, and that seems to demand your immediate attention, whether any thing else is attended to or not—is *that* the 'bread' that the prophet Isaiah speaks of? and is it the kind of labor that '*satisfieth*'?" Sometimes I think for a while it is; but after a few hours have passed by, when the turbulent sea of my turbulent nature has calmed down, then I think, with oh so much remorse and regret! "No, no; it does *not* satisfy." There is only one thing in this whole wide universe that does satisfy, and that is told in our opening text. "Mary hath chosen that good part which shall not be taken away from her."

Now, to wind up my short Home talk to-day I want to turn to Paul's second letter to Timothy. The veteran saint says, when near his end, "I have fought a good fight, I have finished my course; I have kept the faith." Has any one lived since the time of Paul who could consistently take such words upon his lips? And then he adds: "Henceforth there is laid up for me a *crown of righteousness*, which the Lord the righteous judge shall give me at that day; *and not to me only, but unto all them also that love his appearing.*"

SPECIAL DEPARTMENT FOR A. I. ROOT, AND HIS FRIENDS WHO LOVE TO RAISE CROPS.

STARTING ONIONS IN THE GREENHOUSE.

We first commenced this in 1886. Landreth's people had an onion called the Bloomsdale Pearl, which they said was specially adapted to the South. I was so anxious to see some of them that we sowed them in the greenhouse some time in January. We had beautiful pearly-white onions long before any were seen in the markets. They sold so readily we let them all go when they were about the size of hens' eggs. Next year we planted more, and some of them got so large that we sold them by the pound for 10 cts. apiece. Finally our Experiment Station at Columbus took hold of it, and last season they tested almost all the new large foreign onions offered in the catalogues. Like myself, they decided it was a wonderful success. The point is something like this: With ground very mellow, enriched, and brought up to its highest state of fertility, it is exceedingly important that we have a full even stand of any kind of crop. Now, it is very hard to manage this where we depend on sowing the seed and thinning out. By transplanting you can have exactly as many onions as you need on the ground, and no more; and it can be done cheaper than to sow the seed. *Secondly*, where you sow the seed and weed by hand (for weeds will grow as fast or a little faster than onions), there is an immense amount of labor involved. If there were no little onions mixed in with the weeds, we could with the rake, or by horse power, destroy as many weeds in an hour as we can pull out from between the onions in a whole day, or may be several days. By the transplanting process this may be done as follows: Work the ground up nicely, and let it stand until the weeds germinate. Just before you set out your plants, rake the whole surface thoroughly, so as to kill every weed. Now plant your big onions—that is, onions that have passed the weedy stage. They may have bulbs the size of beans, and be perhaps from 3 to 5 inches high. Stretch a string over your fine mellow ground—or, better still, a clothes-line. Run a roller over the line, so it will make the cord leave its print in the soft soil. Now make holes two or three inches apart along this line, and put in your onions. For making the holes, we take a hoe that has been broken from the handle, or, rather, we take the handle part with the shank attached. We grind this shank to a sharp point, and then we have a dibble that can be used standing up. A man can make holes with it on the mark almost as fast as he can walk. A boy goes over with a basket of onions, and puts an onion in each hole.

Onions are so easy to transplant that they will grow almost any way. They should be taken up from the greenhouse or seed-bed, as we do cabbage, celery, and tomato plants. Saturate the ground with water, and dig out the onions with a fork so as to get every one of the fine fibrous roots. We have done transplanting with only *small* boys, and had every onion grow. In fact, the boys get along so fast that they have the ground all covered before I know it. You can plant these onions even quicker than you can plant sets. Of course, you want nice onion ground—soft, mellow, and rich. I do not know how many onions can be grown on an acre. Our Experiment Station suggests that, with these large varieties, you may get over 1000 bushels. Our friend "Joseph," who writes for many of the agricultural papers, has been working in the same line.

Be careful about planting *many* of the large foreign onions, for they are not suitable for keeping; and with much wet weather they may rot on your hands, or even while in the ground. Our Experiment Station gives the preference to the Spanish King, or Prize-taker, onion. These will grow as large as the onions that are imported in fancy crates.

I notice in the agricultural papers there have been several claims as to the originator of this new method of raising onions. Like most of these new (?) things, however, it often transpires they are not new at all. The *Ohio Farmer* gives an article from some one who has been for many years doing this same thing by starting onion seed in an ordinary hot-bed.

If you are going into the business you had better arrange to commence *selling* the onions as soon as you can pick out one here and there the size of a hen's egg. Peel them, cut off the roots, tie them in neat bunches, and deliver them around to the houses before they have a chance to get dry. If you get them real early you can commence by putting only half a pound in a bunch. In almost any neighborhood they will go off at a nickel a bunch—that is, if nobody is ahead of you. When they begin to go slow, give three-fourths, and then a whole pound for a nickel; and finally, if you get a nickel for a 2-lb. bunch you are not doing a very bad business, especially if you have a yield of any thing like a thousand bushels per acre. Such onions will sell almost every month in the year. The Experiment Station has tested this plan for raising ordinary onions, to be sold by the bushel or barrel in the dry state, and think it a success. You can have your rows absolutely straight, and you can have just enough onions in your row without any thinning, and you get rid entirely of *hand-weeding* I am inclined to think they are right about it. It will, however, necessitate some sort of hot-beds, cold-frames, or greenhouses; and if you are going to use the onions green, you ought to be near a town or city.

HOW TO BE SURE OF GOOD SEEDS.

When our good friend Landreth inaugurated the plan of cremation, or burning up all the seeds before the 1st of January, I thought it was going to be a wonderful advance; but I have changed my mind somewhat. There are a few sorts of seeds that had better be burned up—parsnip, salsify, and perhaps onion. All the rest are nearly if not quite as good for another year. Instead of burning up the onion, however, I would use them to raise onion-sets, or sow them thick in the greenhouse, as mentioned above. We have sowed onion seed two years old for several years, for the above purposes. I have been surprised to find that, many times, they grew just about as well as new seed. Parsnip seed you can not use in this way. Beans and corn rarely germinate as fully when two years old; but by sowing them thicker you may get a very tolerable stand. There is a difficulty, however. If they should *all* happen to grow, we should have to thin them out; and thinning out corn where it is a good deal too thick is very expensive business. In fact, I have found it to take more time than all the hoeing and cultivating. On the other hand, if only *half* the seeds grow, and we have many vacancies, that is bad. It is true, we can plant in some more; but if you do this, unless you have very careful hands to gather your ears for market they will be all the while giving customers some that is too hard or some that is not mature enough. By the way, I have practiced transplanting corn, and have sometimes thought that, for *extra early* corn, it paid very well. You can get rid of the weeds, get rid of the frosts, and get a *perfect stand*.

Now, then, I want to say something in favor of *old* seeds. Almost every season we have more or less seed that pleases better than any other we ever had before. We had the finest White Plume celery this last season that I ever saw or heard of. The seed was purchased of Livingston, of Columbus. I almost quarreled with him because he charged me so much. I even talked of sending it back. When he assured me, however, that the seed was *extra*, I consented to keep it. Well, we have now about 4 lbs. of that seed left. What do you suppose I would take for it? Why, I should hate to sell it for *twice* the regular price, and take my chances on something I had not tested. Peter Henderson said, a good many years ago, that he did not dare to offer celery seed for sale until he had first tested it *one season*, and I am beginning to agree with him exactly. Some years ago we were greatly pleased with a nice lot of White Egg turnips. I bought a bagful of the seed, and put it in our catalogue. We sold it three years. But our turnips were always bad shaped, tough, and stringy. I kept trying these on different land, thinking the soil was not suitable. Last fall, however, we sent to *Livingston* for some White Egg turnip seed, and were rejoiced to find beautiful bulbs, tender and sweet. In fact, they were sweeter than the Purple-top Globe. But right here comes in another trouble. These last were sown on that beautiful piece of ground where I turned under the Sharpless strawberries (and put on so many ashes)—the ground that gave such beautiful radishes in just thirty days. Now, I did not sow *any* of my old White Egg turnip seed on this nice ground. I became disgusted, and tried only the new. So you see we are all at sea. I do know this, however, that Livingston's seed is *good* with *nice ground*.

Under the circumstances I do not dare to use the old seed again until I have tried a row *side by side* with the new. I have been afraid that some of our large seedsmen (especially where they offer seeds at a very low price) save their seed indiscriminately from every plant that produces seed. Suppose they should save seed from a turnip that produced scarcely any bulb at all; or from radishes that just ran up to seed the first thing they did. Last season we sowed a lot of carrots very early. Well, in the fall a great lot of them ran up to seed. Our celery does this more or less every season. Suppose somebody should save seed and offer it for sale, from celery that shot right up to a seed-stalk the first thing. I do not know *positively*, but I presume such seed would not be worth much if any thing. We want to be slow, however, in drawing conclusions. I will tell you why. I once condemned some radishes because they all ran up to seed without making any bulbs at all. I called the seed-grower a *fraud*. Well, I was so much disgusted that I let them go and ripen their pods. The seed fell out and dropped on the ground, during the cool fall weather, which seemed to be just suitable, and brought forth a great quantity of most beautiful radishes. I judged it was the dry hot weather that made the radishes behave so badly in the spring, and that it was the cool fall weather that made the seed from these same radishes do so nicely afterward. Still, it will surely pay to be very careful about the seeds you sow. Let me give you an illustration.

About the first of June we received an order for 20 cents' worth of Fottler's Brunswick cabbage seed. Our friend sowed the seed, and I guess about every one grew. He put out the plants and raised a fine field of cabbages. He says, however, that the cabbages made nice hard heads of *Jersey Wakefield*. He wanted large cabbages to put away for winter. Nobody wanted these little ones in the fall, so he fed them to his cows, and they were probably worth $5.00 to him. Had they been the real Fottler's Brunswick, he would probably have received $25.00 or $30.00 for them. I think his estimate of only $5.00 on a fine crop of Jersey Wakefield cabbage, even in the fall, was very low, for we often raise them for winter cabbages, and never had any to keep better, or give better satisfaction to our customers. But,, of course, we did not get as many pounds of cabbage to the acre. Did our clerk really make a mistake and go to the wrong bag? Well, *she* thinks it next to impossible, and I do not see how it *is* possible. An ounce of seed costs just 20 cents, and the ounce packages are all put up, a lot of them at once. What is to be done? Candidly, I do not know. If I am to pay $25.00 damages to a man who bought only 20 cents' worth of seed, I think I should prefer to give up the seed business entirely. I would buy seeds to plant, of course, but I should be afraid to offer seeds for sale. I mention this little incident to illustrate why it is that most seedsmen decline to be responsible for the crop. If it were possible that a peculiar state of the soil and weather should make Fottler's Brunswick look like Jersey Wakefield, I should say this was the explanation of it. I have not had experience enough to know.

OUR LIST OF SEEDS FOR 1891.

You will remember how determined I was to cut the list down. Well, I have cut it down some. I have cut off all our long string of tomatoes but three, and some other things in proportion. But the correspondence that was brought out in regard to the subject rather discouraged me. For instance, I was going to drop Louisville Drumhead cabbage; but this brought a wail from a good friend who had been buying of us for years, who said there was nothing like it for his locality. Last season we tried dropping Early Summer, in order to get rid of so many varieties; but we had more Early Summer plants ordered than almost any other kind. The biggest and finest cabbages on our grounds were from a few Early Summer plants left over after filling orders. They looked so fine that we just put in a couple of rows, and so it has transpired with other things. We also dropped the White Egg turnip in our 1890 catalogue; but the White Egg was, during this past season, called for all over town, and was the best early turnip we ever raised. Our Experiment Stations have certainly done a very wonderful work in weeding out duplicates. Friend Green, in this issue, says that Shoepeg corn is the same thing as Ne Plus Ultra and Banana; and we had some on our grounds that was called, I think, Sugar Cream.* We compared it in looks, and put it on the table, and it was so near like Shoepeg that certainly there is no reason for cataloguing the two under different names. This makes *five* different names for one kind of sweet corn.

The Osage melon was introduced with quite a flourish, and it is really worthy of adoption; but it is now pronounced the same thing as Miller's Cream, which came with an equally great flourish, and some of the catalogues have described both without any intimation that they are even alike.

Where are we going to get our seeds the coming season? Well, this also becomes complicated and complex. It would save us a good deal in freight and express if we could buy all or nearly all of one seedsman; but we can't do it. As I get acquainted with our various seedsmen, I rejoice to see that they are, for the greater part, good, honest, faithful, hard-working men. We find excellent reasons for getting a certain line of one man and a certain line of another, and so on. There are certain seeds we greatly prefer to raise ourselves. Others come from men who, we know by past experience, raise exactly what we want. Some might happen to come from one and some from another. If you wish to intrust your orders to me, I will do the very best I can for you; but I can not, under any consideration, undertake to guarantee that the seeds we furnish will *always* give a crop.

RAISING LETTUCE IN A GREENHOUSE, AND THE LETTUCE DISEASE.

I built a small greenhouse, 11½x48 feet, last fall, to grow lettuce in, but my first crop is nearly all gone by damping off. I understood that the Grand Rapids lettuce was proof against that fault. There must be something wrong with the treatment I give them. What do you suppose is the matter? JNO. MAJOR.

Cokeville, Pa., Dec. 24.

[Friend M., for several years back there has been universal trouble in raising lettuce in greenhouses, in just the line you mention. But the Grand Rapids lettuce is so little affected in this way that it has been called rot-proof. My opinion is, that it is mainly caused by imperfect drainage, and too much dampness in the atmosphere. The trouble occurs mostly in December or January, when we have the least sunshine. Sudden drafts of chilly air also—at least at times—have something to do with it. Opening the ventilators so that frosty air may strike directly on the plants will cause them to begin to damp off, say the next day or two, or three days afterward. Taking the sash off entirely when we have a spell of warm weather seems to do the plants a great deal of good. One kind of dampening off is often caused, evidently, by having the plants too close together—say where they are crowded in the seed-bed. I have had the opinion that plenty of air, so as to dry the plants and the soil out, just as they will get dried out between showers outdoors in summer, might remedy it, and I have wondered whether warming the greenhouse by a blast of heated air might not help to get rid of dampness in the winter time. Now, if some of the veterans in growing winter lettuce will tell us more about it, I shall be glad to give them space. When I last visited Peter Henderson he said his neighbor John Hudson, who built six large greenhouses, mostly for lettuce-growing, had been obliged to give it up on account of the dampening-off and rot. He could grow radishes, without any trouble; but he could get lettuce only by making hot-beds in the old-fashioned way, in the open air, stripping off sash to give them sun and rain when the weather permitted. You can get a glimpse from the above of what I expect to do with my new-fashioned greenhouse when I get it figured out. I have already ever so many plans, but they cost too much money for the ordinary market-gardener.]

WHAT IS THE CAUSE OR ORIGIN OF A "SPORT" IN VEGETABLES?

For the last five years I planted but one kind of pumpkin. In 1889 one vine had an entirely different kind from the parent stock, and, being better, I saved seed from the best one to plant in 1890. This year I had at least six or seven distinct varieties from the seed of that one pumpkin, and only one vine from 80 or 90 had fruit like the one saved from. If I plant seed

---

*Burpee's catalogue is just at hand, and he gives *still another* name to the Shoepeg; namely, Quaker Sweet. He also pronounces the much-lauded Polaris potato the same thing as the Puritan—*whew!*

from only one kind the coming season, will it be the same, or go on increasing? Was it a sport or not? I thought they produced the same as the sport. I have some of them yet, just as sound as when picked from the vines. They are a sweet pumpkin. BENJ. PASSAGE.

Stark, Mich., Dec. 25.

[Friend P., you have struck upon something of great interest to me, and perhaps to others. You can, without question, by careful selection, get a distinct variety of pumpkins from the sport you mention; but, if I am correct, a sport is always inclined, more or less, to sport still further; therefore your pumpkins will sport still further unless you by selection hold them down, as it were, to something you have decided on. I wish Prof. Cook would tell me whether I am correct.]

EDITORIAL.

Wherefore do ye spend money for that which is not bread? and your labor for that which satisfieth not?—ISAIAH 55:2.

REDUCED rates to the Ohio State Bee-keepers' Association (to be held at Toledo, Feb. 10 and 11), will be given on all the roads—at least 1⅓ fare, and possibly better. Dr. Mason has the matter in charge.

NEW CATALOGUES.

WHAT is the matter with the new catalogues? If you want them noticed, send them in; and if perchance we overlook it, please jog our memory.

GARDENING AND BEES.

E. L. PRATT says, in the *Apiculturist*, that there is no pursuit that can be worked with bee-keeping to such advantage as gardening under glass.

THOSE OUTSIDE WINTER CASES.

THESE seem to be doing nicely so far in our apiary. The bees seem to be in just as nice condition as those in large chaff hives. So far we feel very much encouraged as to their ultimate success.

THE SLATTED HONEY-BOARD.

THE slatted honey-board is now scarcely ordered, and we have almost ceased making them. Fixed distances and thick top-bars are running it out entirely. Of course, queen-excluding honey-boards are as popular as ever.

HOFFMAN FRAMES.

THESE are growing exceedingly popular, judging by the way orders are coming in for them. It fans E. R.'s conceit mightily to think that he helped to call attention this fall to something so manifestly good and useful in the bee-hives. Mr. Julius Hoffman is a benefactor.

SILO AND SILAGE, BY PROF. COOK.

THE third edition is now out, and more than 25,000 copies have been sold in less than two years. The book will be worth many times its cost to any of our readers who have even a small interest in this wonderful invention in agriculture. Mailed from our office for 25 cts. We will send GLEANINGS and the silo book together for $1.15.

THE NEW DRESS OF THE AMERICAN BEE JOURNAL.

THE Jan. 1st number of the "old reliable," always-on-time bee-publication is before us. While its pages have been reduced to a size slightly smaller than these, the number has been increased to 32 instead of 16 as formerly. Its general appearance and make-up, as usual, are good, and it is printed wholly from new type. With this number the *American Bee Journal* celebrates its 30th year of existence, and we wish it many more happy New Years.

A NEW BOOK BY FRIEND COWAN.

"THE Honey-Bee" is the title of a new book by Thomas William Cowan, editor of the *British Bee Journal*. It contains over 200 pages, detailing the natural history, anatomy, and physiology of the bee. Some handsome original engravings adorn the pages of the book. We have not had time to review it, but we will do so a little later, reproducing a sample of one of the enlarged engravings of the honey-bee, showing the internal organs.

PRINTING PRICE LISTS.

OUR facilities for printing apiarian price lists were never better than now. We have an enormous selection of electrotypes from which to choose; and having put in another new press, we are enabled to do work cheaper and more expeditiously than ever before. A catalogue is now before us which was evidently printed at some local printing-office. A cut of the one-piece section is upside down, and the size of the sections is given at 4½x4¼. We find other errors that would have been corrected by any one who knows any thing about bees.

PAINTED MUSLIN VS. PAINTED TIN FOR COVERS TO HIVES.

SOME one has said, we do not know where, that painted muslin answers excellently in place of tin for covers to hives. Muslin or common cloth is stretched over the board cover, and nailed around the edges. It is then given two or three good coats of paint. Of course, it can not be quite as durable as tin; but if it can be made to answer for several years, we could afford to re-cover the hives. Who has had lots of experience in this matter? If outside winter cases can be covered with painted cloth instead of tin it will make them cheaper still.

QUEEN-EXCLUDERS, AND WHEN TO USE AND WHEN NOT TO USE THEM.

OUR best bee-keepers seem to think that perforated zinc queen-excluders are not a necessity in the production of *comb* honey. The instances in which queens enter the supers are so rare that it is not worth the expense and time in putting them on the hives. For *extracted* honey, excluders are fast being regarded a necessity. Queens are much more apt to enter extracting-combs than the sections. The reason is, because the former are more nearly of a natural thickness; and in the latter, the cells are so deep that the queen is quite discouraged.

THE AMATEUR PHOTOGRAPHER'S HANDBOOK.

We have had a call at various times for a good book on amateur photography; but heretofore we have not been able to furnish something that was up with the times, simple in style, and reliable in instruction. Most of the books are too complex, and suited only for the professionals. Recently our attention has been called to the Amateur Photographer's Handbook, by that very fascinating author, Arthur Hope. It is easy to see that he has been through all the "experiences." His style is so captivating, and so simple and plain, that almost any boy will be enabled to turn out good work. In fact, if he is inclined to run into hobbies he will be carried clear away with the book, and with the subject with which it deals

The work is so excellent that we have decided to place it on our book-list, and can furnish it postpaid by mail, in paper cover, for 75 cts.

THE CAPPINGS DEPARTMENT

Of the *Canadian Bee Journal* is interesting and well edited. It gives the best thoughts of bee-keepers, no matter where uttered, with substantial credit, not only of the writer, but of the bee-journal as well.

YELLOW CARNIOLANS.

A GOOD deal is said in the *Apiculturist* about yellow Carniolans. If they resemble the Italians at all, how are we to distinguish them from the bees from sunny Italy? The typical Carniolans we have tested seem different from Italians only in color. Make the color the same, and we could not tell which from t'other. Who will be the lucky man to introduce yellow *black* bees?

A VISIT FROM A VERMONT BEE-KEEPER.

OUR friend and correspondent, J. H. Larrabee, of Larrabee's Point, Vt., and secretary of the Vermont Bee-keepers' Association, made us a pleasant call last week. He is one of the parties who helped to get up the bee-keepers' camp on Lake George last summer. He is a wide-awake and progressive bee-keeper; and the name "Genial John," as given him by Rambler, seems to fit him well. Perhaps we shall hear more of him later.

THE BRITISH BEE JOURNAL TO SUBSCRIBERS TO GLEANINGS.

UNTIL further notice we will furnish the *British Bee Journal*, published weekly, at the same price as GLEANINGS—$1.00 a year. The regular price of the *British Bee Journal* is $1.50. We are enabled to do this by exchanging a certain number of GLEANINGS for the same number of the *B. B. J.* After the number to be exchanged is taken up, the price will be as heretofore—$2.40 for both.

THE NEW YORK STATE BEE-KEEPERS' ASSOCIATION.

THIS meets Jan. 22, 23, and 24. The character of the discussions and essays, together with the prominent bee-keepers whose names are attached, bespeak a splendid meeting. This three days' session, together with its prominent bee-keepers, will make this convention rank in importance next to one of the N. A. B. K. A. See published program elsewhere. Ernest or A. I. R. expects to be present.

QUEEN-EXCLUDING HONEY-BOARDS MADE OF WOOD.

THESE have been made before with the slots *parallel* to the grain, but they were discarded because of the shrinkage of the wood and consequent moisture of the hive. But the G. B. Lewis Co. are now making them with the slots to go *across* the grain, and they predict their success. By the way, this firm has lately made a dovetailed hive out of ⅝ lumber, and they sell it at a very moderate price. The testimony of all apiarists has been against any thing less than ⅞ inch for the walls of the hive; but here will be a chance for somebody to test the matter.

TWO NEW BEE-JOURNALS.

TWO more new bee-journals were issued Jan. 1, this year. The first that comes to our table is the *American Bee-Keeper*, edited and published by the W. T. Falconer Co., Jamestown, N. Y. It is nicely printed, 16 pages, with a neat and attractive tinted cover. Such bee-keepers as Dr. Miller, Dr. Tinker, Mrs. Harrison, E. L. Pratt, Mr. Holtermann, and others, have written for it. The other journal is the *Bee World*, edited and published by our old friend and correspondent, W. S. Vandruff, Waynesburg, Pa. The latter is a 16-page monthly. Price 50 cts. per year. It starts out well. Success to the new publications, is the wish of GLEANINGS.

THE PROJECT TO MOVE A WHOLE APIARY IN WINTER TO COLORADO.

OUR friend O. R. Coe, still at Windham, N. Y., who, it will be remembered, was proposing to go to some alfalfa fields with his apiary, has settled upon his location, which is Fort Collins, Col. He has ascertained that it is in the midst of the Rocky Mountain bee-plant and alfalfa bloom, and proposes to get his bees into the field early, and be ready for the honey-flow. He is going to move a carload of bees to his new location this winter. In a letter just received he expresses a fear that he may not be able to move the bees as soon as he desires, on account of the almost impassable condition of the roads to the railway station, by reason of the great depth of snow, and the consequent drifts. He writes, under date of Dec. 27:

> Never, since I can remember, have we been so completely blocked in by snow early in the winter, as now. Our roads, many of them, are utterly impassable from drifts—as much so as they were in the great blizzard of three years ago next March.

BALL'S ALFALFA AND SORE THROAT.

A MEMBER of the Root family was suddenly taken in the night with a distressing sore throat, followed by coughing, and difficult and painful breathing. Trask's ointment and gargling of salt water had no effect. Now, there happened to be in the house about half a tumblerful of Ball's alfalfa. This honey was liquid, and of beautiful body and color. Without much faith, this was given to the patient. Almost instantly came relief. That rich and beautiful honey acted like a soothing oil upon a throat raw with coughing. After a little the distressing symptoms returned, and again the honey was administered, with like results, and so we kept up the program until it was gone. Then we trapsed around the house until we found a bottle of white clover. We tried this, but it had no effect. We next gave the patient the scrapings of the alfalfa jar, and, like oil to a hot box, it went to the spot. Temporary though it was, it relieved a great deal of suffering and no little "scare." It seemed to cut the mucus, and protect the raw sores in the throat.

[The above from Ernest sounds pretty strong for alfalfa honey; and although I confess I do not understand why alfalfa honey should have any particular virtues over other clover honey, the facts in the case given seem to decide that there must be a difference somewhere. If this be true, then may it not reasonably be presumed that honey from other plants may have special virtues for particular ailments.]

STATISTICS.

THE other day a correspondent, having in view the preparation of an essay to be read at a farmers's institute, desired us to furnish him with statistics as to the number of colonies in the United States, the number of pounds of honey and wax produced, etc. There have been no reliable statistics made, although some pretty good guesses have been given. It was estimated, two or three years ago, that there were 300,000 bee-keepers in the land, and that the number of colonies, if each owned not less than ten, would be 3,000,000. Allowing 10 lbs. per colony, the annual product would be 30,000,000 lbs. But the probabilities are, at this date, that the number of bee-keepers has increased to 500,000, and that the annual product of their hives has increased at least in proportion. The government statistics as touching honey which we have had so far would be too unreliable to quote.

DISCARDING OLD THINGS AND TAKING UP NEW ONES.

FOR a good many years GLEANINGS has been slow in adopting improvements in bee culture. One reason of this is, that, more than a dozen years ago, there was quite a protest against introducing so many new fixtures. The protest was just, and I confess I feel now a good deal of anxiety when so many new things are coming up, being illustrated and offered for sale; and I do believe that we should always be slow in bringing to our apiaries different arrangements. It is well to present these things and discuss them; but before adopting them I would let our Question-box corps give their opinions. If a change is to be made, let us have the reasons in full for demanding the change. Let us take the Hoffman frame as an example. It is by no means a new thing, but its revival is new. While I feel somewhat doubtful as to whether it is going to obtain a permanent place in our hives, there are two reasons just now for its adoption. Out-apiaries are taking a place in our industry that they never did before; and there is also a strong demand for something to do away with the burr-comb nuisance. If the bees *will* build combs, have them build them where they are worth money instead of where they are a nuisance. To do this we want fixed distances; and if we want fixed distances, perhaps nothing better presents itself than the Hoffman frame. Please remember, friends, that A. I. Root, while he lives, is going to protest and hold back against the introduction of any thing new until there is some very good and plain reason for burdening the brotherhood with new and additional expenses.

THE NATIONAL BEE-KEEPERS' UNION.

THE 6th annual report of the General Manager, Mr. Thomas G. Newman, Chicago, Ill., is before us. Mr. Newman says:

"When attorneys are defending cases in courts, they often cite the suits previously decided, which favor their argument, or are analogous to it. * * * * When bee-keepers are their clients, they should be able to point to decisions or points of law in favor of the pursuit. * * * * In the first case defended by the Union, Judge Clementson remarked: 'This case involves new points of law upon which there are no rulings of the Supreme Court. We have no law upon which to instruct a jury.' That was in the Freeborn case, in Wisconsin, which the Union had defended so vigorously that the complainant lost his grip in the first round, and it was literally kicked out of court. We have now secured several decisions, notably the one in the Supreme Court of Arkansas. These not only save trouble and annoyance to bee-keepers, but also expense to the Union, by the prevention of petty lawsuits.

"Now, if city councils or town boards are anywhere troubled by a complainant, and asked to pass an ordinance declaring bee-keeping a nuisance, and to prohibit it within the corporate limits, etc., every member, together with the mayor, the city attorney, and the one making the complaint, are all dosed with copies of the Supreme Court decision, that 'bee-keeping is not a nuisance' *per se*, and the matter is at once dropped—killed by the decision of the Supreme Court of Arkansas!"

In the one point of establishing precedents, the Union has performed a grand work; and even should it now be disbanded, these precedents will go on, having their influence just the same; but there is no likelihood of the Union being disbanded so long as T. G. Newman remains back of it; and under his efficient management we have no doubt that it will continue its good work. It has two more cases on hand, and the General Manager is in hopes that they will be landed in the Supreme Court of their respective States on account of the valuable decisions that will be, without question, rendered in favor of the bees. The Union has a balance on hand in the treasury of $621.18. It has engaged attorneys for the defense of the several cases above mentioned; but Mr. Newman says we shall have use for all the money on hand, and the dues for the next year, as the cases are reached on the docket. To become a member, send $1.00 to the General Manager, as above.

OLD SQUARE CANS FOR CALIFORNIA HONEY; HOW CALIFORNIANS ARE BREAKING DOWN THEIR MARKET.

IT is a well-known fact, that square cans are used almost exclusively for shipping kerosene from the East to the Pacific coast. After being emptied they are filled with other liquids, and shipped back again. The worst part of it is, they are being used largely for extracted honey. It is true, they are scalded out, and then the first quality of extracted honey is put in and sent by the carload to the East. Some cans that our men have examined leave us in doubt as to whether they were ever scalded. Sometimes the flavor of the honey is seriously deteriorated, and at other times it is scarcely perceptible. Our friend and correspondent, J. F. McIntyre, a Californian, it will be remembered, has written against the use of oil-cans for packages for honey.

The great difficulty in the way is, that the California markets, at present, will not pay the difference between honey put up in new square cans, and that put up in those formerly used for kerosene. And still another thing is, that these oil-cans can be had for 50 cts. per case less than the new ones; and some of our Western bee-keepers, looking to immediate gains, buy the cheaper packages. If they will reflect a moment, they will see that, in time, they will ruin the Eastern markets for all California honey, or, at least, make it so it will drop a cent or two—a thing that California bee-keepers can not afford to have happen.

Now, if you Californians *must* use coal-oil cans, use some alkali to cut the residue of grease that clings to the inside of the cans. Hot water will not remove it; but a very little weak ammonia will. Yesterday we cut the top off from one of those oil-cans in which had been shipped us some first quality of honey. We were suspicious of the flavor, and hence decided to investigate. The top being removed, we found that a thin deposit of black grease clung to all the six sides of the can. Hot water would not budge it. I then told one of the boys to get one of our 20-cent bottles, holding nearly a quart of ammonia. It is rather weaker than the ordinary commercial article, and is used for washing purposes. Two taplespoonfuls of this were thrown into the topless can. After shaking it around for a minute, the black grease came off entirely, and the sides of the can were as bright and clean as a dollar. I am not sure but that a single tablespoonful of commercial ammonia, mixed with about half a cup of water, would do the same. Remove the cap, pour in the liquid, screw the cap down, and then give the can a good shaking. If this does not remove a lot of black, greasy, inky-looking substance, then it will not do as it has done for us here at the Home of the Honey-bees. I should like to have some of our friends in California try this, and then scald out with hot water, and let the cans stand upside down to drain.

It may be argued, that, on a carload of cans, it would make the ammonia rather expensive. A day's time, and about a dollar's worth of ammonia, according to our markets, in its original form, will make enough to renovate a whole carload of cans. This expense is small in comparison with the ultimate reduction of a cent a pound on California extracted honey. Unless old cans are renovated by an alkali, like ammonia, or new cans are used, the bee-keepers of California will be doing themselves irreparable damage. E. R.

SUCCESS IN MAILING A QUEEN TO AUSTRALIA; THE BENTON MAILING-CAGE AND GOOD CANDY PUT TO A SEVERE TEST.

ABOUT a year ago, one of our customers, Mr. Æneas Walker, of Queensland, Aus., sent us an order for two tested queens. We put them up in the regular Benton cage, and provisioned them the best we knew how, but with very little hopes, however, of even the cages ever getting through to their destination, to say nothing about the queens arriving alive in the event they did. There are some restrictions in the Australian mails, and we feared the magnates over there would hold them when they got into their jurisdiction. The cages went through all right, however, but the queens were dead. Our customer, Mr. Walker, wrote to us that the bees had, by their general looks, died within only a day or two — starved to death—their food having been entirely used up. We regarded this at the time as a success, in so far that we delivered two queens in ordinary Benton cages, clear into the country of Australia, alive, and that, if we had just put in a little more candy to have lasted them two or three days more, we could have reported entire success. On the 10th of last October we replaced the two queens, sending them this time in larger Benton cages. One was a tested honey queen, and the other an untested. You will see by the letter below that the tested honey queen arrived in safety, after a journey of 37 days. The untested, for some unaccountable reason, with her attendants, died. Mr. Walker writes:

> *My Dear Mr. Root:*—I am very much pleased indeed to be able to report that the tested honey queen and her attendants arrived here in safety on the 15th inst., having thus had a journey of 37 days. They had consumed only about half of their candy, so that either the number of bees sent with the queen must have been considerably less than in the first instance, or the weather must have been cooler; but any way, it is now satisfactorily demonstrated that queens can be sent safely by mail from America to Australia. The untested queen and her accompanying bees, I regret to say, were dead; and they must have died early in the journey, as less than a quarter of their candy had been eaten.
>
> ÆNEAS WALKER.
>
> Queensland, Redland Bay, Nov. 24.

Both queens were put into the same kind of cages, and the candy was made from the same batch. It is one of those things that we can not explain, why, under precisely the same conditions, one lot of bees should die, and that the other should live. It is very possible (a fact which our correspondent may have failed to observe) that a single bee might have stuck to the candy, directly in front of the opening, and thus prevented the others from obtaining the food. The journey through the mails may in time have dislodged the bee from the candy, and, of course, all apparently died from some unknown cause. This has, in fact, happened several times, as the returned cages showed. The more I think of it, the more I am inclined to believe that this must have been the cause of death; for certainly an untested queen is supposed to stand more in the mails than an older tested one.

Mr. Walker has ordered four more queens, all to be sent in Benton cages. The size of cage to which we are limited in the mails is 5x2x1½ inches, and it is to be covered with a wire screen, protected by a movable wire lid. The Benton cage which we sent conformed exactly to that size. The number of bees which we put in each cage was 35. It is well known that the Benton cage proper has three holes. In the center one we put a thin wooden partition. We filled one of the end holes and half of the center partition with candy, the bees occupying the rest of the space.

I am explicit in all these details, in order that all queen-breeders may accomplish the same thing if they desire, or, at least, attempt it. By way of a feat, I hope that some of our extensive queen-breeders will try the same experiment. They can afford to throw away at least one queen to see what they can do, and Mr. Walker certainly will not complain if he receives a nice Italian queen-bee from America, in good order, especially if no charge is made.

The Benton cage is capable of wonderful results; and if others are equally successful, or more so, it will be a great boon to Australians, and to bee-keepers living in other remote parts of the world from us.

I omitted to say, that we are obliged to put on letter postage—that is, 12 cents per half-ounce, or fraction thereof. This will make the postage on a package such as we sent, $1.04 per queen. Queen-bees in the size of packages indicated above are not admitted to all countries; but the Postal Guide says that we can send them to the Argentine Republic, Belgium, Bulgaria, Chili, Columbia, Congo, Dutch West Indies (Curacoa, etc.), Egypt, Guatemala, Hayti, the Hawaiian Kingdom (Sandwich Islands), British India, Italy, Liberia, Mexico, Paraguay, Portugal and the Portuguese Colonies, Roumania, Siam, Spain, and Switzerland, as "samples of merchandise;" and to Austria, Hungary, France, Germany, Greece, Luxemburg, the Netherlands and Netherlands Guiana, and Sweden, provided postage is fully prepaid thereon at the letter rate; viz., 5 cents per half-ounce or a fraction thereof.

You will observe that Australia and her provinces are not included; but I think there will be no trouble when full letter postage is put on.

Later.—Since the above was written, a letter comes to hand, from Mr. John Sench, under date of Dec. 18, acknowledging the safe arrival of two queens at Port Morant, Jamaica, West Indies. Nov. 25, last year, we sent two select tested queens, put up in Benton cages, the same size as above given, and put on letter postage; namely, 5 cts. per half-ounce in this case. Our customer does not say just *when* the queens arrived; but presuming that he wrote immediately, or soon after their receipt, the bees must have been nearly a month on the way. We have tried sending queens several times before in *Peet* cages, with Good candy, but there was a failure in every instance. We must attribute the secret of this success to the Benton cage, for the candy, namely, powdered sugar and honey, mixed to a stiff dough was used in the Peet cages before. Perhaps I should add, that the queens were first sent to a forwarding house in New York, and from there they were sent direct to the address as above. E. R.

IMPROVED EXCELSIOR INCUBATOR

Simple, Perfect and Self-Regulating. Hundreds in successful operation. Guaranteed to hatch a larger percentage of fertile eggs at less cost than any other hatcher. Send 6c. for Illus. Catalogue.

Circulars Free. **GEO. H. STAHL, Quincy, Ill.**

HONEY COLUMN.

CITY MARKETS.

MILWAUKEE.—*Honey.*—The demand for honey, both comb and extracted, has been ruling dull, and supply has accumulated somewhat. But during the past week a better trade has been enjoyed. Can quote market fairly easy. For 1-lb. sections, best, 18@19c; good, 16@18; common, 10@12. Extracted, in barrels, kegs, and cans, white, 8½@9½; amber, 6½@8. *Beeswax*, 25@28.
A. V. BISHOP,
Jan. 17. 142 W. Water St., Milwaukee, Wis.

CINCINNATI.—*Honey.*—There is a fair demand for comb honey at 16@18c a lb. in the jobbing way for choice white. Demand is good for extracted honey at 6@8c a lb. on arrival. There is a good supply of all but Southern honey, which is scarce. *Beeswax.*—Demand is good for beeswax at 24@26c a lb. for good to choice yellow on arrival.
Jan. 16. CHAS. F. MUTH & SON, Cincinnati, O.

NEW YORK.—*Honey.*—Market quiet and unchanged. We quote extracted light Fla. at from 8@8½ cts. per lb., and California from 7@7½c per lb. *Beeswax* from 27@29 cts. per lb.
F. G. STROHMEYER & CO.,
Jan. 20. New York City.

ALBANY.—*Honey.*—We have received up to date 2150 cases of comb and 234 packages of extracted honey. As we expected, there is an increased demand for dark extracted honey, and we are nearly out of stock. Comb honey is moving off slowly with no change in prices. White, 16@18c; mixed, 14@15c; buckwheat, 11@13c. Extracted light, 9@10; dark, 7@8.
CHAS. MCCULLOCH & CO.,
Jan. 21. 339 Broadway, Albany, N. Y.

ST. LOUIS.—*Honey.*—We quote to-day's honey-market: Choice white-clover comb, 1-lb. sections, 18c; good, 17c; fair, 15@16; broken comb, 10@12. Extracted, white clover, in cans, 9@10c; dark, 7@8c; Southern, in barrels, 5½@6½. *Beeswax.*—Selected, 25½@26; prime, 25@25½; dark and burned, less.
Jan. 10. W. B. WESTCOTT & CO., St. Louis, Mo.

SAN FRANCISCO.—*Honey.*—Extracted honey firm 5¾@6½. Comb honey scarce; 2-lb., 12@14c; 1-lb., 14@16. *Beeswax* in demand at 24@24½c.
SCHACHT, LEMCKE & STEINER,
Jan. 12. San Francisco, Cal.

DETROIT.—*Honey.*—Comb honey is selling slowly at 15@16c; white clover and basswood scarce. Extracted, 7@8c. *Beeswax*, 27@28c.
Bell Branch, Mich., Jan. 19. M. H. HUNT.

ALBANY.—*Honey.*—The stock of honey here never was so light as now so early in the season, and now is the time to sell. Light comb, 15@18c; dark, 12@14c. Light extracted, 9@10c; dark, t@8c.
Jan. 15. H. R. WRIGHT, Albany, N. Y.

ST. LOUIS.—*Honey.*—Market unchanged. Demand quiet for comb. Extracted in good inquiry at 6@7c in barrels. *Beeswax*, prime, 25c.
Jan. 19. D. G. TUTT GRO. CO.,
St. Louis, Mo.

COLUMBUS.—*Honey.*—White clover in demand at 19@20c. Extracted honey very dull.
Jan. 19. EARLE CLICKENGER, Columbus, O.

FOR SALE.—4 60-lb. cans white-clover and basswood extracted honey, on cars at Morrison, Mo., at $6 per can.
MILLER BROTHERS,
3-4-5-6-d Bluffton, Montgomery Co., Mo.

FOR SALE.—50 cans of light extracted honey, at 8½ cts. per lb. Entire lot at $5.00 per can.
S. A. SHUCK, Liverpool, Ill.

FOR SALE.—1200 lbs. extracted white-clover honey in barrels or 60-lb. cans, as desired.
1tfdb E. J. BAXTER, Nauvoo, Ill.

FOR SALE.—Choice honey in sections, cans, and C. pails. Send for price list to OLIVER FOSTER,
12-tfdb. Mt. Vernon, Ia.

CONVENTION NOTICES.

The Northeastern Michigan Bee-keepers' Association will hold its annual meeting on Wednesday, Feb. 4, at the Commercial House, Port Huron.
W. Z. HUTCHINSON, Sec'y.

The 8th semi-annual meeting of the Susquehanna County Bee-keepers' Association will be held at Montrose, Pa., Thursday, May 7, 1891.
H. M. SEELEY, Sec'y.
Harford, Pa.

The Eastern Iowa Bee keepers' Association will meet Feb. 11 and 12, 1891, in Maquoketa, Iowa, at the Dobson Town-clock Building, to commence punctually at 10 A.M. There will be a large turn-out of the prominent bee-keepers of the State. There will be a question-box, free to all, in which any question that you wish discussed can be presented and answered. Let all be on hand, and bring in your report for 1890, spring count, or from May 1. The people of Maquoketa kindly furnish us a free hall.
FRANK COVERDALE, Sec.

The following is the program of the proceedings of the annual convention of the Ohio State Bee-keepers' Association, to be held at the Merchants' Hotel, Toledo, Feb. 10, 11.

FIRST DAY, TUESDAY, FEB. 10.

Convention called to order by the President. Reading minutes of previous meeting. Receiving members, and payment of annual dues—50 cents.

How can this convention be made interesting and profitable?—Volunteers. Recess.

The relation of honey-eating to longevity.—E. E. Hasty.

Appointment of committees.

AFTERNOON.

Address of the President, Dr. A. B. Mason.

Bee-laws.—Dr. C. C. Miller, Marengo, Ill. Recess.

Getting used to a thing.—E. R. Root, Medina, O.

Question box.

EVENING.

The principal cause of the failure of the honey-crop in my neighborhood.—C. F. Muth, Cincinnati. Recess.

How can honey-producers best reach the trade? or, Do we need a Union trade-mark?—Miss Dema Bennett, Bedford, O.

Question-box.

WEDNESDAY MORNING.

Queen-rearing.—Dr. G. L. Tinker, New Philadelphia, O.

Spacing of frames, and its relation to brood-rearing and swarming.—J. B. Hains, Bedford. Recess.

Reports of committees. Deciding place of next meeting. Election of Officers.

Freight classification for bee-keepers.—J. T. Calvert, Medina.

Advantages of foundation.—W. Z. Hutchinson, Flint, Mich.

AFTERNOON.

Moving bees to catch the honey-flow.—H. R. Boardman, East Townsend, O.

Perforated zinc in extracting.—Volunteers.

Unfinished business. Recess. Question-box.

Bedford, O. MISS DEMA BENNETT, Sec'y.

The Southwestern Wisconsin Bee-keepers' Association will hold its next convention in the Court-house, at Lancaster, Grant Co., Wis., March 25 and 26, 1891. All who are interested in apiculture, and conventional work on the same, are cordially invited to attend. The following are the topics for essays.

1. Spring dwindling and cure—Edwin Pike, Boscobel.
2. Enemies, and how to avoid—N. E. France, Platteville.
3. Foul brood and cure—N. E. France.
4. What are the most destructive birds that kill bees—Edwin Pike, Boscobel.
5. Queens, introducing and raising—A. E. Coolie, Mt. Hope.
6. What is the best way to ventilate a cellar for bees to winter in?—H. Evins, Wauzeka.
7. How shall our membership manage to sell our honey crop to the best advantage?—Edwin Pike.
8. Does it injure a queen to be clipped?—M. M. Rice, Marion.
9. Which will produce more honey—a colony allowed to swarm, counting in the work of the swarm, or one kept from swarming?—Delos Ricks, Boscobel.
10. Which is the most profitable way for increase—by artificial swarming or by natural swarming?—M. M. Rice.
11. Robbing, cause and cure—H. Gilmore, Georgetown.
12. Is it profitable for a farmer to keep bees?—E. S. Morse, Fennimore.
13. Location of apiary and stands, tools, etc.—B. E. Rice.
14. Other occupations for bee-keepers, that pay well to combine with apiculture—Mr. Prideaux, Bloomington.

E. PIKE, Pres. B. E. RICE, Sec'y.

PRICE LISTS RECEIVED.

Since our last issue we have received price lists of bees, hives, and apiarian supplies in general, from the following parties:

J. B. LaMontagne, Winter Park, Fla.
S. F. & I. Trego, Swedona, Ill.
Gregory Brothers, Ottumwa, Ia.
M. Richardson & Son, Port Colborne, Ont.
W. D. Soper & Co., Jackson, Mich.
Geo. E. Hilton, Fremont, Newaygo Co., Mich.

The following are from our press:

Colwick & Colwick, Norse, Texas.
Walter S. Pouder, Indianapolis, Ind.
W. H. Laws, Lavaca, Texas.
John Nebel & Son, High Hill, Mo.

SPECIAL NOTICES.

We will pay 25c each for a limited number of copies of GLEANINGS for Feb. 1, 1882.

OUR EARLY PURITAN POTATOES.

By an error in our seed list, published in our last issue, the above potato was advertised at last year's prices; whereas the price in italics at the bottom of the list should refer to Early Puritans as well as to all the others. Potatoes are worth more than $1.50 in Medina, at present, for table use.

PANSY SEED FOR SUBSCRIBERS.

We have a new supply of papers of mixed pansy seeds such as we had last season. Any one who sends a dollar for GLEANINGS can have a packet free, providing he mentions it at the time, and his name is not entered for any other premium; otherwise the price will be 10c per packet. These packets of pansy seeds are usually sold for 25c. By the way, I should be glad to get a report from those who sowed the seed last season.

THICKNESS OF TOP-BAR IN OUR FRAMES.

A great many of our patrons seem to have the impression that our so-called thick-top frames are the only ones having thick top-bars. These have top-bars ⅞ in. thick; but where frames are accurately spaced, as in the case of the Hoffman, closed-end, or Van Deusen frames, top-bars ⅝ thick are just as much a preventive of burr-combs, and are abundantly heavy for strength. The added ¼ inch to the top-bar of the thick-top frame is necessary only where frames are not well spaced, as they are not likely to be without some kind of self-spacer. Remember, then, that all our frames have thick and wide top-bars, except the old-style all-wood frame and metal-cornered frame, which have top-bars ⅜x⅞.

Leahy M'f'g Co.,

Undoubtedly the Largest Plant in the West,

Built exclusively for the manufacture of Apiarian Supplies. **One and One-Half Acres Floor Space.** We sell as **Cheap as the Cheapest**, and our goods are as **Good as the Best**. Parties will do well to **write us** for estimates on large orders. We will send you our catalogue for **your name on a postal card.** Address **LEAHY MFG. CO.,**
Higginsville, Mo.

LOOK HERE! Do you want a grocery with good business, in good location?
3tfdb **BOX 40, German, Darke Co., O.**

Wants or Exchange Department.

WANTED.—To exchange 1 lb. thin Vandervort fdn. for 2 of wax. Samples and testimonials free.
2-7db C. W. DAYTON, Clinton, Wis.

WANTED.—To exchange fruit-trees, for a 10-inch foundation-mill.
JAMES HALLENBECK, Altamont, Albany Co., N. Y.

WANTED.—To exchange Acme harrow, swell-body cutter, and Planet Jr. horse hoe and cultivator, for Barnes saw, bees, honey, or offers.
2-tfdb MODEL STAMP-WORKS, Shenandoah, Ia.

WANTED.—To exchange Excelsior hand-inking press, 25 fonts type, material, etc., also 5 vols. American Encyclopædia, for honey (crop 1891). A rare chance for smart boy to make money. Write for particulars. S. S. LAWING,
2-3d Henderson, Webster Co., Mo.

WANTED.—An active Christian who understands the management of bees, etc., to take one-third less or more, interest. Location better than—well, I will not say; write any way. P. O. LOCK B. N,
2-tfdb Williamson, N.Y.

WANTED.—To exchange, 1 saw, with counter-shaft and belt. Will exchange for wax.
2-3d L. L. ESENHOWER, Reading, Pa.

WANTED.—To exchange hand-made crayon Portraits, 18x22 size, for 100 lbs. good honey. Satisfaction guaranteed. Send your photo. to 2-3-4d
J. M. WELLS, 1552 Monsey Ave., Scranton, Pa.

WANTED.—To exchange apiary of 150 colonies of bees. Will take any kind of farm stock, goods or groceries. ANTHONY OPP, Helena, Ark.

WANTED.—To correspond with parties having potatoes, onions, apples, and honey for sale. Prompt attention given to correspondence. Consignments solicited. Prompt returns made.
EARLE CLICKENGER, 121 So. 4th St., Columbus, O.

WANTED.—To exchange tested or untested Italian queens for sections or 6-inch Root foundation mill. J. W. TAYLOR,
3-4d Ozan, Hempstead Co., Ark.

WANTED.—To exchange strawberry-plants, the leading varieties, for poultry.
3-4d DOUGLASS BROS., Hamburg, Mich.

WANTED.—Situation with a bee-keeper, fruit-grower, or market-gardener.
3d R. H. BRICKER, Slate Lick, Pa.

WANTED.—Situation, by a single man, with some one in the South, to work in apiary; willing to do other work. Can give reference. Address
3d A. J. HUSKEY, Marystown, Johnson Co., Tex.

WANTED.—To exchange Black Cochin chicks for first-class magic lantern. They are No. 1 birds, and the best of winter layers; and should like to exchange bees for Golden Wyandott chicks. I would keep bees until spring. Good reference given.
3tfdb D. F. LASHIER, Hooper, Broome Co., N. Y.

SEND 10c and the names and addresses of 10 bee-keepers and we will send you a monthly paper, "Buckeye Farmer" for one year.

STRAY STRAWS

FROM DR. C. C. MILLER.

BEES had best be broodless yet.

The *Apiculturist* for January is a souvenir number with a nobby cover.

IF ALLEY doesn't stop fooling with that self-hiver he may make a success of it.

THE RAMBLER thinks there is a bonanza before us in developing a bee that will work on red clover.

"TO SELECT WELL among old things," says *American Bee Journal*, "is almost equal to inventing new ones."

BAIT SECTIONS in supers are strongly recommended, in *Api.*, by A. C. Tyrrel, as a partial preventive of swarming.

ANOTHER in the dairy business. The *Bee World* is going to give, "as it were, the cream of apicultural literature."

DZIERZON, at the age of 80, is living a quiet life, at Brieg, Silesia—just the age of Langstroth, who was 80 last Christmas.

UNITING BEES by spraying with cold water is recommended by *C. B. J.* It cautions against the use of flour if the bees should get wet.

An Austrian bee-keeper has invented an artificial comb made of tin, having cells the natural size. Didn't Quinby do that long ago?

THE NATIONAL BEE-KEEPERS' UNION is in good shape financially—$621.18 in the treasury. It's a power, for all it has only 331 members.

THE AMERICAN BEE-KEEPER is beautifully gotten up. Let's see. We've had *A. B. J.*, *B. B. J.*, *C. B. J.*, and now we have *A. B. K.*

THE *C. B. J.* has started opposition to the *Review* in the dairy business. It's going to give "the cream of all apicultural literature."

WIDE SPACING in the super, to keep the queen from laying there, R. M. Reynolds says, is all bosh. He has tried it 14 years with 275 closed-end frames.

In the month of January,
Likewise the month of February,
The busy bees they store nary
A drop.

"IN CUBA," says A. W. Osborn, in *A. B. K.*, "500 colonies can be kept in one apiary any time of the year, but they must be hybrids, not pure blacks or Italians."

ARTIFICIAL COMB is one of the just-going-to-be things in Cincinnati this time. Allen Pringle, who tells about it in *C. B. J.*, doesn't enthuse over it to an alarming extent.

THE "HEDDON POLLEN-THEORY," Heddon thinks, "is now a practical, settled science." May be; but sometimes he calls a thing settled just because it agrees with his opinion.

MRS. L. HARRISON, in *A. B. J.*, resolves to "endeavor to have one-pound sections weigh one pound." When you get 'em all to weigh exactly a pound, Lucinda, tell us just how you do it.

THE BEE WORLD is the name of a new 16-page monthly, 50 cents a year, published at Waynesburg, Pa., by W. S. Vandruff. A paper of the same name was published years ago, wasn't it?

DZIERZON SAYS: "The want of air fit for breathing, and perhaps also of water, is the cause of bees becoming restless, which ignorant and superficially informed people attribute to excessive heat."

NUMBER TWO, in *Canadian Bee Journal*, wants to know about "close-framed friends," in GLEANINGS, page 891. It's "closed-frame friends," Number Two. There is no such thing as "close-framed friends."

SOME SAY ventilation of the cellar is not needed; that upward ventilation of the hive will keep the air pure. Now look here: how much upward ventilation will make the air pure in a cellar filled with rotten cabbage?

Mouse poison, as prepared by P. Lattner (*American Bee Journal*), is a tempting dish. Make dough for a sweet cake, mix in it powdered strychnine, and bake. Must be capital; but, my! if the children should get hold of a piece!

Cold, according to Heddon, is the prime cause of bees consuming pollen, and the consumption of pollen in winter the sole and direct cause of diarrhea. Wouldn't it be shorter to say that cold is the prime cause of diarrhea?

The *C. B. J.* is going to have, after Feb. 1, "machines which will cast every line of type as it is set, and will do about three times as much work as an ordinary compositor." Say, Mac, will it have an automatic proof-reading attachment?

The Manager of the Bee-Keepers' Union says, "It will take money to do it, but it is the Supreme Court decisions that we need, for they will do more to guarantee to bee-keepers their rights and privileges, than any thing else!" Wouldn't it cost less to get some good laws made?

Dibbern's Hive-carrier is much the same as my rope. Instead of being all rope, it is "two square hard-wood sticks, a little longer than the hives, with pieces of stout cloth tacked between the ends." Carry by the cloth. His will be fitted on the hives more readily. Mine will stir up the bees less.

The Nebraska Bee-keeper is making trouble. *American Bee Journal* inquires if it has met its death, and Gleanings announces its birth on the anniversary of the same. It's too good looking to die unregretted. Nearly every one of those which died had a look as if somebody made it himself.

Germany is ahead of us. Instead of trying to secure for bee-keepers their rights through a series of tedious decisions, they have got a square law: "We, the king, decree: The privilege of bee-keeping to all inhabitants on their own property;" and, "Apiaries will be protected by civil right and law." How much of that Union's $600 would it take to get us such a law?

Tapeworm Remedy.—The *Medical Brief* says: The most successful pumpkin-seed remdy is made as follows:

Peeled pumpkin seeds, -	3 ounces.
Honey, - - - - - -	2 ounces.
Water, - - - - - -	8 ounces.

Make an emulsion. Take half, fasting, in the morning, remainder half an hour later. In three hours' time two ounces castor oil should be administered. Used with great success.

GENERAL CORRESPONDENCE.

QUEEN-REARING, ETC.

ABOUT THOSE CELL-CUPS, AND WHY DR. MILLER FAILED WITH THEM.

On page 19 I see that our friend Dr. Miller made nearly an entire failure in using my plan of rearing queens in artificial cups during the past year, and says: "I'd like to know what the trouble was." Beside me, also, lies a letter from another person, residing in Bloomington, Ill., in which he says that he has "utterly failed in getting a single cell built out from the cups," and closes his letter by saying, "Could you not give us an article in Gleanings that would throw some light on the subject?"

I am very much surprised at these failures, for I have letters from Texas to Canada, and from Maine to California, telling of the success the different individuals have had in rearing fine queens by this artificial-cup plan, used over queen-excluders. If the complaint had been about getting the queens fertilized when tried out of the honey season, I should not have been surprised; for I find that success can generally be obtained only during a heavy honey yield, in getting queens thus fertilized, although some colonies will keep laying queens in both stories through the whole season.

Now, not knowing all of the circumstances connected with these failures reported above, I do not know that I can give the reason why. I have never had less than three cells built from a single trial of from twelve to twenty cups, in all of my seven years' trial of the plan; and during the last five years I have reared all of my queens by this plan at all times, except very early in the season and late in the fall, at which times there will not be bees enough above to make a success of queen-rearing. While I have never had less than three cells completed, I have, time and time again, had the whole twelve or twenty, according to the number of cups put on a stick, completed, and the average number for the five years could not have been less than two-thirds of all the cups started. I think that Ernest will bear me out in this last, as he saw an average of the work done, he selecting the hives he wished opened. To those who do not meet with success when trying the plans given in Chapter VII. of my book, I would suggest that they try the plan, using a colony made queenless and broodless, as given in Chap. VI., only using the artificial cups instead of the queen-cups, as there spoken of, and put royal jelly in these as I directed in Chap. VII. If they fail then, I shall not know how to account for it unless they are not able to handle the little larva carefully enough so as not to injure it. After being successful with the queenless colony, next try it over the queen-excluder, always remembering that unsealed brood should be above when the prepared cups are given, and that the bees should be liberally fed if no supplies are coming from the fields. It is also well to allow these two frames of brood to stay "upstairs" 24 hours before the prepared cups are given to the colony.

Now, dear reader (any one who should happen to fail in using the plan), don't think hard things of Doolittle, for I have no more interest in "scientific queen-rearing" than I have in the A B C or any of the other bee-books, except that it is my "baby." I let the manuscript for the book go for less price than I get for this manuscript which I am at this moment writing, giving the whole thing to the world free, except the compensation for my time in writing the manuscript, and sent out the matter *with the only wish* that it might *bless* the bee-keepers of the world, many of whom are being blessed, if their words are a criterion to go by.

Some seem to think that the size of the perforations in the zinc excluder has something to do with the success or failure of raising queens in an upper story; but I think this is a mistake. The larger part of that in use in my apiary is the old Jones make, which is large enough to let many smallish queens through, while the rest in use is that sent out by Dr. Tinker. The Tinker make is the finest of any thing I have ever seen, and is simply perfect; but, so far as I can see, it gives no better results in queens than do the old uneven perforations of former years.

BEES ROARING.

Another correspondent writes: "It has been cold of late, and has now warmed up to quite an extent. Upon passing about among the bees I find some colonies which are roaring in a way similar to what they do in the summer. Can you tell me what the trouble is? and is it a sign of diarrhea?"

Bees having the diarrhea to an extent sufficient to spot the hives on the inside, generally give forth the roaring sound spoken of by the correspondent; but it is a rare thing that any single colony becomes thus uneasy so early in the season, much less a large number of colonies. From former experience along this line I should say that, during the cold spell preceding this roaring, the bees consumed nearly all of the unsealed honey inside of the cluster; and when the warmer weather occurred, the cluster broke up and the bees went out around on the sealed honey, uncapping it and taking more honey into the cluster, or what will be the cluster when re-formed again. This always causes a merry hum to be heard; and, if I am right in the matter, it could be no sign of diarrhea. Should the roaring be long continued with but slight abatement, the bees will gorge themselves with honey, and diarrhea will very likely result. Should it continue, I would look into the matter some warm day to see whether I could find out what the trouble is, experimenting on only one or two at a time, to see if matters could not be improved. It may possibly be that a mouse has got inside of these hives, and, by his running about, the bees are disturbed. If so, get him out and fix the entrances so that none can possibly get in again.

G. M. DOOLITTLE.

Borodino, N. Y., Jan. 12.

[As I have said before, I repeat again, that the artificial cell-cups that I saw at Doolittle's were accepted and built out by the bees to perfection. In our own apiary we did not have entire success with the cups, but some were completed, and hatched queens.] E. R.

MANUM'S VISIT CONTINUED.

OVERSTOCKING; HOW TO LOCATE OUT-APIARIES; IMPORTANCE OF WIND-BREAKS; MOUNTAINS AND HILLS, AND THEIR EFFECT ON APIARIES.

"Good morning, Mr. Barber; this is a beautiful morning."

"Good morning. Why, Manum, you came near getting the start of me. I am not accustomed to sitting up so late as we did last night, and I overslept this morning. Well, here is the paper you called for last night; and while you are mapping out your apiaries I will get breakfast."

Breakfast over—and a good one too—Mr. B. takes the map, and, after looking it over carefully, asks a few questions.

"Manum, how high is that range of mountains east of you, that appears so very near?"

"I believe, Mr. B., that they are 1200 feet high."

"I suppose the whole side of that mountain is covered, more or less, with basswood, is it not?"

"No, not by any means. If it were, I should not care to exchange locations with you. There are, however, a few basswoods scattered here and there on the mountain-side, and at the base they are more plentiful; but the hills, as we call them, that you see scattered over the country, have a good many basswoods on them; and as my apiaries are nearly all located near such hills, I have a fair basswood range."

"What do these double circles indicate, where there is a circle within a circle?" asks Mr. B.

"Those indicate apiaries belonging to other parties. For instance, Nos. 1 and 2 are owned by Mr. Charles McGee, who, by the way, is one of my boys, or was a few years ago, and he is the Charles I was talking to in GLEANINGS of Dec. 1. Nos. 3 and 6 are Mr. H. Stilson's apiaries. No. 4 is Mr. Fred Dean's; No. 5, E. Cox'; No. 7, T. Fish's; No. 8, E. A. Hasseltine's; and Nos. 9 and 10, Mr. L. O. Thompson's. The single circles indicate my own apiaries."

"Well, Manum, it seems to me that your territory is pretty well occupied, and, I should think, overstocked."

"Yes, Mr. B., I think there are bees enough on this little territory, especially in a poor season. When I started in the business there were none within 20 miles of me, except a few box hives here and there."

"What are all these marks, zigzagging from one apiary to another?" asks Mr. B.

"Those are the highways which I travel over in going to my apiaries."

"How far from your home are your apiaries, Mr. M.?"

"They are from 3 to 15 miles from home. These little squares on the diagram represent square miles; hence by counting the squares between each apiary you get the distance they are apart; and the circles, as you see, represent a radius of two miles from the center."

"I notice that your Meach yard is nearly surrounded by hills. Do you consider the hills of any advantage?"

"Yes, most certainly. In the spring the hills are a protection from winds; and as there are many basswoods on them they are an advantage in that respect, as they afford good forage all around and near by. I consider this my best basswood range and my poorest clover range. This year in August, I had 7 colonies starve in this apiary before I was aware they were so short of stores."

"How happened you to locate two apiaries so far from home; viz., the Ferrisburgh and Varney yards?"

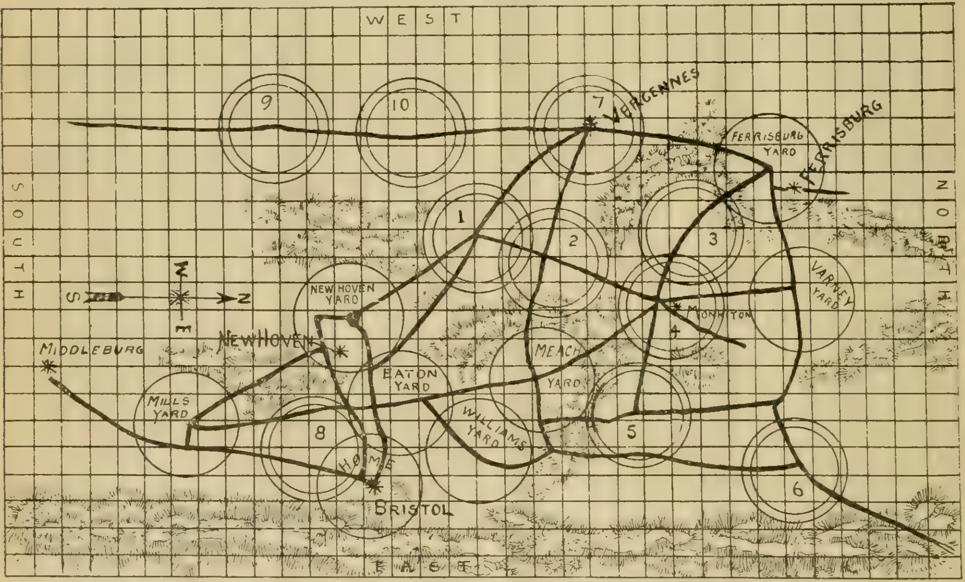
"I was obliged to go that far to get beyond and out of the range of my neighbors, as you see I was completely hedged in."

"I notice, Mr. M., that some of your apiaries are so near each other that they overlap each other's territory. Do you think they do as well where they are so near together?"

"No, sir, I do not, especially in a poor season; but in a good season I see no difference, all things being equal. I should prefer to have my yards five miles apart if I could so locate them; but owing to the formation of the hills, and the difficulty in finding just the right spot, and also permission to set an apiary, I was obliged to locate some yards nearer and some further apart than I really wished to. Bee-keepers who have never located out-apiaries can not fully comprehend the difficulties one has to contend with in selecting a suitable location. When selecting one I aim to acquaint myself with the surrounding country, after securing the spot for the yard. I go out prospecting through the fields and woods, to satisfy myself whether the location is a suitable one or not; and by the aid of a strong field-glass I am able to determine whether I am in a good basswood range without very much traveling, if I do this prospecting during or soon after the basswoods bloom, as then the blossoms and blossom-leaves enable me to see a basswood-tree at a distance."

"Do you always select a sheltered spot for your yards?" asks Mr. B.

"I always aim to, that my hives may be protected from cold winds in the spring; for I notice that, where my yards are most protected, the colonies in them are the strongest when the honey season opens; hence from these I get the best results, especially in poor seasons. To illustrate: My Williams apiary is on a sidehill, the upper half being well protected from the southeast and north wind. The lower half is protected only from the south wind, and that not fully. Now, it is a fact that the upper half always winters better, and the colonies are always strong at the approach of clover bloom; hence I always get much more honey from the upper half of that apiary. It is very seldom that I lose a colony in winter or spring from the upper half; and another feature that is very noticeable is, I very rarely have to feed those colonies in the upper half, as they usually have enough honey for winter, or nearly so; hence, from my experience with this apiary, I am satisfied that protection is very essential, and I am building high tight board fences, as fast as I can get to it, around such of my yards as are not well protected by nature; and, Mr. Barber, I am more thoroughly convinced than ever, since we have had these five poor seasons in succession, that, in order to be successful, we *must* have our colonies *strong* at the commencement of the honey season."



OUT-APIARIES AMONG THE MOUNTAINS IN THE VICINITY OF BRISTOL, VERMONT.

"Manum, do you ever move your bees from one yard to another in the fall, to have them fill up for winter?"

"No, I do not, because there is not much difference in one of my locations from the others, so far as fall honey is concerned."

At this point we arrive at Mr. Barber's bee-cellar, where I find 80 colonies already stored for winter. This cellar, if I remember correctly, is 20 x 30 feet. It is not a dry cellar; and as the bottom is often very wet, the hives are set on plank, which are set on hive-caps some 15 inches high, and are packed in as closely as they can be conveniently, and four hives high. Mr. B. removes the honey-board, and spreads a piece of heavy ducking over the frames, and over this a cushion three inches thick to take up the moisture. He aims to keep the temperature up to 50, and at no time does he allow it to get below 45. Mr. Barber tells me that his loss in wintering very rarely reaches 3 per cent. He is a very careful manager, and has made bee-keeping a success, and, I understand, is quite forehanded, having made the most of his money in the bee-business.

In order that we might have a longer time to visit, and a better opportunity to view the country, Mr. Barber took me to Canton, a distance of six miles from his house, where I took the cars; and, as I bade him adieu, I did so with the feeling that from him I had received a vast amount of knowledge which well repaid me for my journey. A. E. Manum.

Bristol, Vermont, Jan., 1891.

[Your map, Mr. Manum, is suggestive and interesting—the more so because it shows the mountains, hills, and roadways, and how you have to drive to reach each one. The first thing that attracted my attention, when I arrived at Bristol, was those mountains on the east. "Oh!" said I, "Mr. Crane" (with whom I was riding), "that is where Mr. Manum gets his basswood honey." But I was a little surprised to learn that there was little or no basswood on those mountains, and that his reliance for honey from this source is from certain hills; but those mountains furnish that beautiful Vermont white poplar for sections, so popular with the Eastern bee-keepers. I am doubly sorry now that I could not, or, rather, did not, steal the time to drive around with you over those zigzag roadways, and visit some of those yards. I learned a good many things when I went around the country with Mr. Elwood, and I have no doubt at all but that I could have picked up many a valuable item from you in a similar drive.

Overstocking must be a rather complicated problem with you. Why, what a lot of *other* bee-keepers there are around you! I should think you'd quarrel, so close together as you are in some cases; but I am reliably informed that there is the best of feeling among all of you, even though the proximity of your several apiaries must cut off, to a certain extent, your earnings from each apiary. When we get our apiaries down on a map we find out for the first time, perhaps, how close we are together. Say, Dr. Miller, what would you do in such a locality? Would you preach bee legislation, priority claim of locality, or would you move out?] E. R. R.

THE DOVETAILED HIVE.

SUGGESTIONS AND CRITICISMS.

Friend Root:—I have studied your Dovetailed hive well, I think, especially in connection with the subject of frames, i. e., thick top-bars, closed ends, etc.; and since you ask for criticisms and suggestions, and I have some to give, here goes:

I am thoroughly dissatisfied with the hive I have been using. I think, after nine seasons' experience, together with my study of hives through the medium of books, journals, etc., I have a pretty good idea as to what kind of hive I do want. Your Dovetailed hive comes nearer to that idea than any other now on the market, so far as I know. I have had a few in use the last year similar to it, and, after a year's trial, I am sure I have not miscalculated my preference, unless it may be in the matter of a brood-frame. But I do not like your hive in the following particulars:

1. I think that, although I have never used a closed-end frame, it is, nevertheless, the style of frame I want. But in two respects the combination of that frame with the Dovetailed hive is faulty.

(*a*) If I understand your description of the hive, the frame is of the same length as the "swinging" frame, having a bee-space at the end. I don't know what anybody wants of a bee-space back of closed-end frames. To me it would be a most prodigious nuisance. The frame should be about 3/16 of an inch shorter than the brood-chamber inside, leaving 3/32 of an inch play at each end. This would insure ease in manipulation where there is apt to be slight irregularity in length.

2. When you have a hive and frame so nearly adapted to reversing, either in part or entirely, why not have them quite so? The hive would be made with the ends rabbeted so that, if any one wanted to hang a frame in the hive he could do so, but have a stick of the right size to fill it up if desired. A single wire nail would hold it in place, and it could thus be easily removed. I would not make the frame to hang, but to sit on rests fixed on the bottom-board. Either one of two devices would do well for rests. One would be a tin T, ⅜ of an inch high, tacked on to the bottom-board, front and rear. The one in front would have to sit back about an inch from the entrance. The other device would be a metal strip at each end, ⅛ inch thick, by ⅜ wide, set its thickness in notches in the side cleats of the bottom-board, and just inside the ends of the brood-chamber. If there should be any danger of these strips bending from the weight of the combs, about two small blocks could be placed under each for props. We should thus have a brood-chamber and a frame, either one of which could be easily reversed. To reverse the entire hive we could simply turn it upside down, loosen the wedge or screw, press the frames to their place, and then key up again. Top and bottom bars should, of course, be the same thickness, and that not more than ⅝ of an inch, perhaps less. Secondly, you make your top-bar 1 1/32 inches wide, leaving only ¼ inch between them. Is not that rather close? I should think one would frequently want to take out a frame without moving other frames or wedges. There would be a poor chance to get a finger-hold. I know the object of such a top-bar is to prevent burr-combs. This brings me to my "thirdly."

I am not prepared to give up the honey-board. I have worked several years without it and a few years with it, and I am quite in love with it. That, you know, will go far toward preventing burr-combs. But, aside from that, the honey-board has three valuable features:

(*a*) I would have it queen-excluding always. It is comparatively seldom, it is true, that a queen will go into section boxes. Still, she is liable to go with a cluster anywhere when the brood-chamber is crowded, especially when there is a paucity of drone comb below in swarming time, as I desire there should be. I have known it to happen half a dozen or more times a year, and that is often enough to spoil considerable honey. When working for extracted honey especially, the queen will always go into the upper story unless prohibited, and I do not want her there.

(*b*) When hiving in contracted brood-chambers, much pollen is carried into the sections unless something is done to prevent it. A queen-excluder reduces the quantity to such a minimum as to amount to practical prevention.

(*c*) Bees will often gather up the cappings of honey or brood as they are gnawed off the combs below, and work them into the combs above, which mars the honey greatly. I have never heard any complaint of this from others, but I have often noticed it. But I have never known it to happen above a queen-excluder. The young bees are also less prone to travel over and stain the lower part of the sections. Wide and thick top-bars, of course, will have the same effect to some extent, but I think the honey-board is better.

(*d*) I would have the depth of the frame reduced at least two inches. This would be too great an innovation to urge upon you; but I wish the standard frame were not more than seven inches deep.

There, you have my idea before you. Introduce the modifications I have given, and I believe you will have the model hive for comb and extracted honey. GEO. F. ROBBINS.

Mechanicsburg, Ill., Jan. 10.

[If you will refer again to our description and engravings of the improved Dovetailed hive, shown on page 745, Oct. 15, last year, you will see that, where the closed-end frames are to be used, the ends are to be enough thicker to take up the extra space, but leaving a play sufficient to remove the frames. Note carefully the sectional drawings on 745. No, it would not do to leave the usual ¼ inch between the closed ends and the end of the hive. As we construct them for the Dovetailed hive, they can be used either to stand or to hang. A *hanging* closed-end is a little better for the ordinary hives in use. It will not topple over, and will kill fewer bees. Of course, if it is desired to make it reversible, all you have to do is to draw the nails, or, better, leave them out and use instead the bottom-rests.

In regard to queen-excluding honey-boards for comb honey, you are against the great majority of comb-honey producers, who say they do not want the excluders. For extracted honey they are a good thing.

Are you sure you are right about the excluders keeping pollen from the sections? Of the great representative bee-keepers that I visited last summer, not one, if I remember correctly, used excluding honey-boards for comb honey.

Pollen in the sections is usually the result of too much contraction in the brood-nest: and the tendency of the times is against contraction to less than 8 L. frames. It is far better to have a big, rousing colony on 8 frames than a medium one on 4 or 6 frames. If perforated zinc will keep pollen out of the sections, it ought to out of the brood-nest when drone-guards are on.

☞ What you say regarding cappings from old brood-combs is, to a certain extent, true; but I don't quite see how perforated metal will make much difference, unless it be the slight obstruction from the perforations. Some of the prettiest and whitest comb honey I ever saw was produced in Vermont and York State, without perforated zinc honey-boards. As supply dealers, and the largest manufacturer, of perforated zinc, we ought to boom that article, whether for *comb* or extracted honey; but we don't want bee-keepers to buy it for *comb*-honey production *if* it is not needed.

I know that top-bars $1\frac{1}{32}$ inches wide leave rather scant room for the fingers. With a follower and fixed distances, either closed-end or Hoffman, it gives no trouble.

After you have used closed-end frames for a while, you may modify your views somewhat in regard to the plain, slatted honey-board. Fixed distances will permit of narrower and thinner top-bars in the riddance of burr-combs.]

E. R.

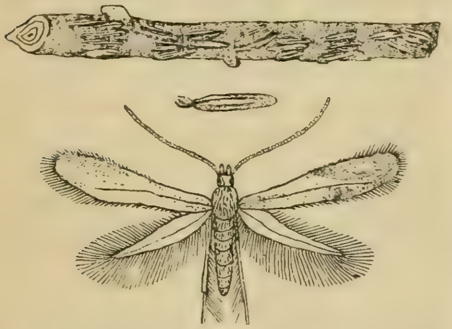
THE TINEID MOTH.

PROF. COOK TELLS US ABOUT THE LITTLE EGG-SHAPED COCOONS ON THE APPLE-TREES.

Mr. Chester Olmstead, East Bloomfield, N. Y., desires to hear through Gleanings of the eggs (?) which "literally cover" the twigs of his apple-trees. These are not eggs, though they look so much like them that it is not strange that Mr. O. mistook them for eggs. He, however, seems in doubt, for he adds, "I take them to be eggs."

These are the cocoons of a beautiful little moth, *Bucculatrix pomifoliella*, Clem.

As we see by the cut below (the single one is shown natural size), they rest side by side on the twig, often as many as eight together. Sometimes they are so abundant that they do "literally cover the twig," as Mr. Olmstead states. They are a quarter of an inch long, white in color, and elongated, as seen in the figure. The cocoon is ribbed, and firmly attached to the twigs. Next spring a beautiful tiny moth will come from each of these cocoons, unless the pupa has been destroyed. This moth is less than an eighth of an inch long, and measures but little more than a fourth of an inch from tip to tip of the wings when the latter are spread. The fore wings are white, with yellowish reflection. There are three brown spots on each wing—one a mere dot at the tip of the wing—as seen in the figure. The posterior wings are triangular, and beautifully fringed, as is generally the case with the *Tineid* moths. The moths lay their eggs early in the spring. In June the caterpillars may be seen eating the leaves. If disturbed they fall from the leaf, letting themselves down by a thread of silk which they spin for the purpose. They are nearly half an inch long when full grown; are dark yellowish green, reddish toward the head, which is brown. This first brood—the insect is double-brooded—spins its cocoons on the twigs, but among the leaves they are not so conspicuous as are the winter cocoons. The second moths come forth in late summer; the second larvæ feed in autumn, and the brown pupæ pass the winter in the elongated cocoons. Thus we have the life-history of this beautiful and interesting little *Tineid* moth.



These moths are so called because they belong to the family *Tineidæ*. As we should suppose, the moths of this family are very small. Thus they are sometimes called *Microlepidoptera*. Our common clothes-moths, some of the worst grain insects, and leaf-miners also, belong to this family.

In looking at these cocoons I find many with holes either at the end or on the side. These holes show that some parasite has eaten up the insects, matured, and gone forth to destroy other of our insect enemies. Again, on the buds of the twigs, and crowded in between the cocoons, many plant-lice eggs are to be seen. These are minute black eggs. They will hatch in the spring just as the leaves unfold; and the plant-lice which come from them multiply so rapidly that, unless checked by other insects—which is usually their fate—or the orchardist, they will do much harm.

These tineids are so small that they usually do little harm. If so abundant in June as to seriously damage the trees they would quickly succumb to the arsenites—the same that so speedily destroy the codling-moth and the canker-worms.

WEARING GLOVES.

DRESS FOR LADIES WHEN AMONG BEES.

In working with bees I always wear gloves. I think Dr. Miller has mentioned it in some of his articles, also, that he thought I would give them up some day. You need not tell him that I said so, but I don't believe I ever shall. Aside from the saving of stings (and gloves have saved me a good many stings), it doesn't seem to me as if I could ever endure the sticky propolis on my fingers.

I sew a pair of white sleeves securely to the top of my gloves, leaving no opening for the bees to enter. I use white, because the bees seldom, if ever, sting white. I used to fasten the sleeves to the shoulder with a safety-pin, but I found that very cross hybrids managed to get in a good many stings on my shoulders above the sleeves, as the sleeves did not reach quite far enough. I now make the sleeves very long, so they will reach well up on the shoulders, and fasten them together in the back with a little strap, buttoning them together in front with a similar strap. It takes much less time to put them on in this way.

One objection to wearing gloves is the time it takes to get rigged up for work. But I really believe I can work faster and better with than without them, for I do not feel so nervous about stings. Another advantage is, that they materially help to keep your dress clean—or, rather, the sleeves do.

There is one thing I decidedly do not like to do with gloves on; and that is, to clip a queen. I always draw a long breath when the operation is over; and I confess that, if Dr. Miller is within reach, I always carry them to him to clip.

I have never been able to get a glove that quite suited me. I have never tried rubber, as I imagined I should not like them, for the smell of rubber is very disagreeable to me. For some time I have used buckskin; but they are very heavy and warm, and decidedly uncomfortable, and, when well stuck up with propolis, are not very handsome, to say the least. I wish some one who has had some experience with rubber gloves would tell how he likes them, or any other kind of glove, for that matter. The subject is a very interesting one to me.

Perhaps if our bees were all pure Italians it might make some difference in my views. We have requeened all our colonies, giving them all Italian queens, so next summer I may have a chance to see how much difference it will make.

Another thing that bothers me is, to know what to make my aprons of. I have tried gingham, calico, and oil cloth. I don't like any of them. I want something that honey will not soak through readily, as I should like to keep my dress clean. By wearing two aprons at a time, and changing them very often, I have managed pretty well. But that is troublesome, and makes lots of washing, and I should like something better. I dislike the oil cloth, for it has such a disagreeable smell. I am thinking of trying bed-ticking this summer. It doesn't seem to me that honey ought to soak through very easily. I am afraid the objection will be, that it is so heavy and clumsy. Have any of the ladies ever tried it? If so, please tell us how you liked it. EMMA WILSON.

Marengo, Ill., Jan. 12.

[My good friend, you are striking on real practical matters in your suggestions, and this is just what we want. By the way, why not have paper aprons, and burn them up as fast as they become soiled—something like the Japanese paper handkerchiefs? Honey and propolis, to say nothing of beeswax, are very trying on one's clothes. Like yourself, I always feel nervous when my hands are daubed with either honey or propolis. Our remedy is a cheap wash-basin and a towel. If it were not for the looks of the thing, some sort of apron would be a very convenient thing for men as well as for women, during the honey season. Can we not not hear from more of the women-folks who have been helping among the bee-hives?]

KEEPING RECORD.

HOW IT CAN BE DONE BY MEANS OF A BRICK ON THE HIVE-COVER.

Friend Root:—Allow me to offer a few suggestions, in line with Wm. Muth-Rasmussen's article in Dec. 1 GLEANINGS. The general criticism to all such plans is, that they are too elaborate, taking too much time to learn the system, and then the chances of the stones or bricks being moved out of their position by visitors or children; and even dogs and cats jumping on the hive might do it. For the bee-keeper who has but few colonies, some such plan might be best; but for him who numbers his hives by the fifties or hundreds it is too cumbersome. I have been thinking of a plan adapted to such by using bricks, which I think are much to be preferred to either stones or number cards, for the reason they can be turned in three positions, each of which can have its meaning. These three positions in which a brick may be laid, viz., side, end, and flat down; by dividing the hive cover into three positions—front, rear, and center, would give nine points; and by dividing each of these positions into three parts, we have in all 18 points. Nor is this all. The brick may be placed on any one of these divisions in two ways—lengthwise of the hive or crosswise of the same, making in all over fifty different arrangements of the brick on a hive, which would certainly satisfy all the requirements of the most exacting.

The information needed or desirable in regard to the contents of a hive may be grouped under three general heads:

1. Of bees. This would include brood, eggs, and larvæ in all stages; also quality and quantity.

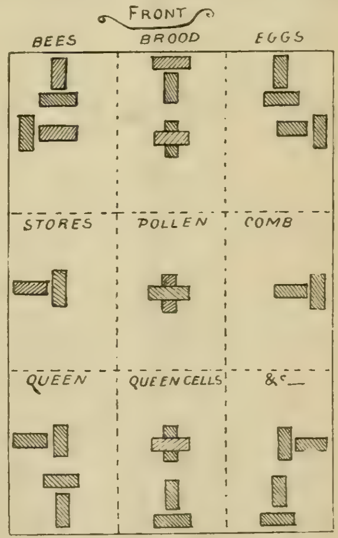
2. Stores, referring to both honey, pollen, and wax.

3. Queen, referring to quality, age, condition, etc.

Those for these three natural divisions of topics correspond with the three divisions or general places on the hive-cover; and, for convenience, say we call the front third the bee division; the central third the stores division, and the rear part the queen division. Then a brick placed anywhere on the rear third of a hive would mean something about the queen; on the central third, always something in regard to the stores; and one on the front third, always something in regard to bees or brood; and the absence of a brick from any of these places would signify that all is right, and no particular attention is needed.

Again, we might generalize and simplify our system by having the brick standing on end always mean immediate attention, and its position on the hive indicate in what particular point the attention is needed. Each bee-keeper can elaborate the system to suit his or her special needs.

Here is a figure of a hive-cover and its suggested divisions, which will make it clearer.



HATCH'S SYSTEM OF HIVE-RECORD BY BRICKS.

It might seem, at first glance, that one would need three bricks for every hive; but in practice it is not so; we have used a plan something like the above for years, although not so comprehensive, and find that one brick for each hive is usually ample. For keeping track of queens, our plan is to mark the date of her birth at the time of clipping, which is done only in the spring of each year, usually in May, on the front of the hive, in small figures; thus, "89" would indicate that the queen in the hive thus marked is clipped, and that she was raised in 1889. Next year, when time to clip comes around, and I find a clipped queen in a hive, I simply make a dash under the old mark. This shows that the queen has been found, and always shows how old she is. If a queen with unclipped wings is found, this shows she was raised after the spring clipping was done the year before, and therefore must be of last summer's raising. The old date is rubbed out, and the new one substituted, leaving off the 18, as that is always understood. When the clipped queen comes out with a swarm, the date is rubbed off the old hive and put on the hive in which the queen is put. The fact that the date is erased from a hive shows it has swarmed. If one wishes to know which the swarms are, some other mark is necessary. I have used this queen-record for years, and find it better than any other I have tried or seen in use.

As to keeping a record of each hive as to times of extracting, I have never found it practical, preferring rather to go over the hives with supers on, and removing some frames from those which are full, and substituting empty frames from those not full, putting the full ones in their places, thus getting all or nearly all ready to extract at once, which means economy of time and labor, and usually the honey is none the worse for the longer time on the hive. I speak from an extracted-honey producer's standpoint, for I have never done much with comb honey, twenty colonies in one season being the most I have ever run for comb.

Ithaca, Wis., Dec. 13. C. A. HATCH.

[Friend H., I like the idea of bricks, for several reasons. They are clean-looking, are not affected by the weather, uniform in size and shape, and stay securely where you place them. Something a little lighter, say half of an ordinary brick, would perhaps do as well; but as we have not got it, perhaps we had better use the brick. I have always felt that stones, from their awkward, ungainly shape, give the apiary a disorderly appearance; then when you lift off the cover they are almost sure to roll off. Thanks for your suggestion.]

EXPERIENCE IN CARP CULTURE.

ONE OF OUR BEE-FRIENDS TELLS OF HIS SUCCESS.

Friend Root:—When you first began to publish notes on carp culture I at once became interested, having a fine site for a small pond. I had long contemplated building a pond for raising some common fish, cat or perch; but now I turned to the carp. I built a pond by making a dam across the valley, and another at the upper end 100 ft. distant, thus turning the brook, which is kept running by a spring, around the pond; but a second and smaller one is pouring into the pond, just strong enough to keep it full, or nearly so. When full of water it was 3½ feet deep; but I soon learned that this was not sufficiently deep. In November, 1886, I introduced 10 carp, 18 months old. Shortly after this a severe winter set in, and I cut the ice to save the fish from suffocation; but I learned afterward that this was not necessary.

The spring of 1887 opened, and I kept a close watch upon my breeders, as I was anxious to have them lay; but I determined not to feed them, and that they should shift for themselves, just as I would have treated common fish. I would notice the fish only on rare occasions; but I found out that they were all alive later in the summer, as some boys while in bathing kicked up so much dirt that all came to the surface, and appeared to gasp for breath. But no sight of eggs or young fish could be found. Not draining the pond, I can not tell absolutely whether any fish were hatched in 1887, but I believe not.

The winter of 1887 was very severe, and I kept cutting the ice as before; but the pond began to leak. Fortunately the leak was stopped; and when the spring opened, the pond was full of water.

This time I decided to feed them, and coax them to lay. I accordingly fed about 2 qts. of corn at one time. I would drop it down in a certain place, and every day I rolled up my sleeves and felt down to the mess, and it would disappear in two or three days; but I could never see the carp play about the feeding-place; but when it was all gone I would replenish it. Thus I fed them for nearly four weeks, when I saw them spawn, May 11, 1888, and in a few days the pond was just thick with eggs. I had thrown some willow branches into the water, and these were all covered with eggs. I then discontinued feeding them, and have not fed any thing since. I began to think that these eggs might not be fertilized, and failed to hatch, so I broke off some of the branches with the eggs adhering, about enough to make a buttonhole bouquet, and placed them in a flat-shaped gallon jar filled with water, and set them out in the garden. In two days I found them all hatched. I counted about 40 fish; but they were so small, and had so much of a water color, that it was difficult to see them.

I left them in the jar, and in a few days they were all dead; but I had the satisfaction of knowing that the eggs in the pond were nearly all hatched, and no doubt the whole water was full of little fish. The cattle and hogs had access to the pond, and the latter would wallow in it to their hearts' content. I felt satisfied, for I wanted to test the carp in this way. The cows would stand in the water, and I was obliged to fence them off, as the water gave them sore legs. In August we began to notice young fish. I had the boys catch a few with hooks, and they were from five to six inches in length.

Late in October, 1888, we made an attempt to seine out some fish; but the seine was not long enough, and we happened to land a few of the spring hatch, 6 to 7 inches in length, and some of those I introduced in 1887. These fish (introduced in 1887), in the month of August, were stunted by their pond drying out. There were about 30 carp 5 inches in length, from the previous year's hatch. We also caught 5 of the larger ones, which we prepared for the table, and we thought them very palatable. Also a few very small perch were found. The winter of 1888 was very mild, and I watched for more eggs in May, but I did not find one. During these three years the pond had filled up with sediment so that but 18 inches of water remained, and I concluded that it was unsafe to let them winter in so shallow a water. I contracted with a neighbor to take all the carp that we might find. Dec. 4, 1889, we seined the pond, and landed, to our surprise, 180 young carp, of the 1888 hatch, measuring 10 to 12 inches in length, being very uniform in size. Also 5 of the old breeders, introduced in 1886, were caught, 22 inches in length, and weighing from 4 to 5 lbs.; and 24 of those introduced in 1887, weighing from 1½ to 3 lbs., and measuring from 14 to 20 inches, and a solitary one of the 1889 hatch, about 3 inches in length, thus showing that some eggs were laid and hatched. Six perch, about 6 inches in length, with 200 young, about 2 inches in length, were also landed. These six perch, I think, found their way to the pond by accident. They were only about 1 inch long in October, 1888. It is these in company with the carp that no doubt ate all the eggs or young carp if any hatched. But why did the 200 perch survive? I think they are somewhat more spry, and dodge the larger fish, and thus escape from the cannibals. Not feeding the breeders, and the chilly weather during May, may also have caused the shortage of eggs. You will notice that the growth of the carp does not approach that of many other breeders who take extra pains in feeding them and weeding out other fish.

The neighbor's ponds were very low during the latter part of 1890. Dec. 24 we seined one pond, which was too shallow to risk any fish in, and transferred them to another; and we find that the year's growth with all the different sizes is even smaller than it was with me. Along with the carp we found hundreds of perch and cat-fish, but could not find a single carp of this year's hatch. I believe if they had been undisturbed for years to come, with 270 breeders, no young carp would survive, even though some might hatch. Another neighbor introduced 30 carp 7 inches in length. In 1887 the pond was flooded. Later, and when we seined it in November, 1890, we found only 4 left. They weighed 7 lbs. each. Also several thousand common fish were found, but not a single young carp. No doubt these four carp lived on the wild fish, which accounts for their weight.

Mr. Root, I do wish you could have seen these four fish. They were as fat as hogs. After these careful observations I have come to the conclusion that the safest way for an ordinary farmer is to make a pond deep (7 feet or more), and proof against overflows. Then stock the pond with young fry in September. I think this by far the safest way to go into carp culture. I should be glad to hear from others who have experimented with carp. L. F. DINTELMANN.

Belleville, Ill., Jan., 1891.

[Friend D., we should also be glad to hear from others; but inasmuch as there is a journal devoted to carp culture, we think it best not to give very much space to it here. You bring out in your communication a fact of great interest to me; namely, that if the eggs be removed from the pond, and placed in a glass jar out in the sun, young carp may be hatched out by the million, perfectly secure from their voracious foes. My impression is, that the principal difficulty with carp-ponds in general is that common fish get in and eat the eggs and young fry. Our own pond has no communication with any other body of water; and yet common fish make their appearance as fast as we can get them out. They are probably brought in by the eggs adhering to the feet of wild water-fowl. Of course, drawing the pond off and sorting them out from time to time will keep these enemies in check. But it needs somebody with a good deal of enthusiasm in the business to follow it up.]

ERNEST'S NOTES OF TRAVEL.

AT DR. MILLER'S, CONTINUED; REVERSIBLE BOTTOM-BOARDS; MICE IN BEE-CELLARS, ETC.

The next morning, Monday, I arose, fully refreshed. The doctor wanted me to stop another day; but I told him I must take the train at noon.

"Well, then, we can not afford to waste any time," said the doctor.

I had a curiosity to know more about those deep bottom-boards he is using, and so down into the cellar we went. He had already put in some 25 or 30 colonies, and the rest were still out. The doctor had told me, if he could only get me into his cellar he could convince me that his reversible bottom-boards were a good thing, and when there I had to assent that they were; although, of course, I insisted that Boardman's plan of leaving bottom-boards off entirely was just as good, and cheaper.

"But," said the doctor, "*I* can not carry hives of bees into the cellar with no bottom-boards, without the bees dropping out and flying all over."

"If you select a rather cool day, I do not think you will have very much trouble; at least, I do not have. Still, I admit that there is a little trouble, occasionally, especially with the hybrids. Latterly we have carried the bees into the cellar with the bottom-boards on the hives. Our carrying - bail catches under the bottom-board, and hive and all is carried in. When there the hive is lifted off its bottom, and placed in position, and so we bring in each hive. The bottom-boards are piled up in one corner of the cellar, and the bodies of the hives are stacked up, *a la* Boardman. So you see, doctor, we have no trouble about bees flying out."

"Yes," said he, "but don't you have trouble by a lot of bees clinging to the bottom-board?"

"We should have," I replied, "if we carried the bees in on a warm day. We wait till the temperature goes down to 20 or 25, and then the cluster will have contracted enough so that, when the hive is lifted off its bottom, there will be no bees adhering. I will make an exception for hybrids. The least disturbance will make them expand their cluster, and boil all over the bottom-board. As we do not keep hybrids to any great extent, and do not propose to, this trouble does not figure very largely with us. I admit, doctor," I said, "that the reverisble boards are a splendid thing. As you do sometimes have a few hybrid colonies, your plan would have that advantage."

"But it won't do for me," said the doctor, "to pile the hives up *a la* Boardman. You may say it is not necessary to have mice in the cellar; but *I* have them, and can't very well keep them out. As I explained to you, I use this coarse-mesh wire cloth to close the entrance to all such vermin. It has a coarse mesh, you see, so the bees can easily pass out."

"Yes," I said, "circumstances do sometimes alter cases. My cellar is made entirely mouse-proof. Still, there was one little chap that crept in last winter. One Sunday evening while Mrs. Root and I were sitting before the grate fire, over the bee-cellar, we heard a peculiar sort of noise. The cat picked up her ears, and seemed interested, and cautiously crept to the point whence the noise proceeded. I said that would never do to have a mouse in the bee-cellar, so down I went with the lantern. I examined a number of bees on the floor, and found that the mouse had been eating at them. It was pretty dark in the cellar, but I ran my hand up, as well as I could, where I had heard the mouse. By holding the lantern up I discovered a sort of black hole. I thrust my hand into it, and was somewhat horrified to find that there had been a fire there at some time or other, though it was, evidently, from no fault of the rodent. This hole was directly under the grate tiling, and it was evident that the heat had been at some time so intense as to burn out the woodwork. I did not care any thing about the mouse; but I made up my mind that our comfortable grate should not run any more that winter. Although I was deeply grateful to the mouse for causing me to investigate the premises in the cellar. I set a trap and caught him. returning evil for good; so you see. doctor, if it hadn't been for the mouse I might have lost all the bees. No, sir; mice do good sometimes, even to bees."

I would say to our readers here. by way of parenthesis, that I had the grate repaired, and now Mrs. Root and I enjoy the comfort of sitting before it again evenings. Although open fire is warm and cheerful, we want it primarily for ventilation. It is well known that a grate is one of the best ventilators in the world: and our house, almost at all times, feels as fresh as a spring morning. As the grate is not sufficient to entirely heat all the rooms, we have independent heat besides. I drop this simply as a hint to some of our readers who may possibly have in mind the building of a new home or the reconstruction of an old one. If the grate is set by an experienced man there will be no trouble from fire. My first grate-setting was very poorly done; in fact, I might say, put up with criminal carelessness.

Well, to return. The doctor and I strolled about the bee-yard, talking about any thing and every thing. Our thoughts finally reverted to bee-conventions. As the air was chilly, we thought we could discuss this matter a little more comfortably in the house, before Dr. Miller's open-grate stove.

I will remark here, that, if I hadn't a grate, I would certainly have an open-grate stove. You will be surprised to see how it will freshen up the atmosphere in the house.

Well, when we had seated ourselves comfortbly, I said to the doctor:

"You have a big talent in helping to liven up a bee-convention. I have been wondering for some time whether we could not employ this gift in some way in Gleanings. In reading your articles, doctor, our readers do not get half a glimpse of your fund of good nature. Now, I have been thinking for some time that it would be a good scheme for you to have a department of short items, where you can give some of your little spurts of fun and friendly clips once in a while."

The doctor very modestly admitted that he did have a talent in that direction, and that he would be glad to use it if we could devise some way whereby he could. To make a long story short, the upshot was that we started a department in our journal, entitled, "Stray Straws." You know the rest, and of its merits and character you are to judge.

As it was approaching the hour of train time, after an early dinner I bade adieu to Dr. Miller, and took the train for Chicago.

A VISIT TO THE OFFICE OF THE AMERICAN BEE JOURNAL.

By looking at my railway guide I found that I had a little time in the city before my western train would take me home. On arriving at the city I made direct to the business place of T. G. Newman & Son, 246 Madison St. On reaching the place I took the elevator and forthwith was ushered to the top floor; and before I was hardly aware of it I was in the presence of the editor of the *American Bee Journal*. As usual he was hard at work at his post, and so likewise was his son, Alfred H., in his department. I wonder whether anybody ever found them other than busy. And being in the heart of the city, I wonder if they are not more or less pestered by visitors. Every thing had the appearance of that clock-work regularity and system that makes the old *American Bee Journal* always on time. They have very pleasant and commodious quarters, and occupy the whole top floor of a large building. After a pleasant chat with both the Newmans, we went back to the office, when, whom should I meet but our friend W. F. Clarke, of Guelph, Ontario, the former editor of the *American Bee Journal*? He was on his way to his home, Guelph, Ont., Can. I was obliged to make my stop shorter than I wished; and after a short visit of perhaps an hour, I took my leave.

DOES GLEANINGS UPHOLD TRUSTS, RINGS, AND MONOPOLIES?

A REPLY TO A DISSATISFIED SUBSCRIBER.

Please discontinue Gleanings, as I do not wish to take a journal that upholds trusts and rings and monopolies, as I see you did in Gleanings for Dec. 15. Alvin L. Potter.

Milan, N. H., Dec. 20.

[Friend P., we will discontinue your journal, of course; but you surely do not state it fairly or truly. Gleanings strives to avoid uncharitable extremes; and our country is certainly *suffering* because of the extreme views taken by some of our people in regard to this matter of labor and capital. The Bee-keepers' Union, which has been such a protection to more than one of us, might be called by a certain class a "trust." It is a combination of bee-keepers to maintain our rights, and to protect us from spite or prejudice. Where men of wealth combine together to wrest from any class of people their *just* rights, Gleanings would by no means uphold them; but when the laboring classes make grievous mistakes in rushing to the hasty conclusion that some of their best friends are enemies in disguise, Gleanings can not well do otherwise than to utter a voice of warning. One extreme is anarchy, and the other is plodding along and letting everybody who is so disposed run over you and help themselves to the fruits of your hard labor, without a protest. The farmers who sold their butter for 10 cents a pound when it was justly worth 25, are a fair illustration of this latter extreme; and small bee-keepers who take their honey to town and sell it for what anybody is pleased to offer them, also belong to this extreme. Just let me give you a point right here.

Most of the readers of Gleanings are acquainted with Dr. A. B. Mason. He is a man who has been largely a servant of the public. He is constantly called upon to preside over assemblies, and, in fact, to manage crowds of people when nobody else can manage them. He has wonderful ability in that line, as you well know; and yet Dr. Mason is a poor man. He makes his living by keeping bees, and by his daily toil in his business of dentistry. He is a devoted Christian, and a good man in every way. Well, at our Detroit convention somebody spoke of the piece of newspaper pleasantry that is going the rounds, to the effect that the poorest *crop* that America ever raised is her "crop" (?) of *millionaires*. Almost everybody says amen to this, and seems to think it is true. Why, I myself have often felt sad about it. Well, perhaps we ought to feel sad; but here is Dr. Mason's reply, as nearly as I can remember it. Said he, "I do not agree. I do not believe a word of it. I wish there were *ten times* more of them."

I protested by saying, "Why, Dr. Mason, I am astonished at you."

He replied, "I repeat it; I wish there were *ten times as many more of them*."

Now, I presume Dr. Mason means this: That it would be a blessing to America if there were ten times as many men with the brains and ability, judgment and wisdom, the skill and experience, to manage large enterprises so as to make them successful. It is these large business enterprises that give our American people work. Now, a man lacking in brains, or a man lacking in *virtue*, can not, as a general rule, manage such large enterprises. An *intemperate* man may manage people and capital a little while; but it can not be for long. The man who becomes a millionaire must be a temperate man, and, to some degree, *it seems to me*, a *liberal* and *honest* man, or he can not succeed. If men become millionaires by trickery and fraud, then all good men and women ought to combine in a ring, trust, or monopoly, and fight them to the bitter end. The fighting should, however, be done in a legitimate and orderly way. We must be law-abiding citizens, and we must have faith in each other, or we shall surely jump from the frying-pan into the fire.

Now, if any reader of GLEANINGS wishes it stopped because of the above position, we will stop it with the kindest and pleasantest feelings, and we will refund all money due. It is quite likely that GLEANINGS *will* lean strongly toward *charity* and faith in mankind, for it does seem to me that our greatest danger lies in too little faith in each other; and this faith and love should be broad enough to reach from the *poorest* day laborer to our *richest* millionaire.]

THE RAMBLER IN WARREN.

HE ENCOUNTERS A SEVERE CASE OF BEE-FEVER; MORE HOFFMAN FRAMES AND NO BURR-COMBS.

Rhode Island hospitality did not end under the roof of Bro. Miller. We rambled to the thriving town of Warren, and to the residence of Dr. J. M. Merchant. Mrs. Merchant desired expert counsel in relation to the doctor's malady, the bee-fever.

We found that the doctor had for many years been subject to feverish attacks, some longer some shorter, but none severe. For instance, the hen-fever had a very thorough run; but the usual appliances of pills, plasters, a sweat (or its equivalent, a little curtain admonition), had resulted in an effectual cure. But now the bee-fever had taken him with the utmost severity. The family supposed it would succumb to the usual remedies, and a little patience on their part. But old and tried remedies had no effect, and the fever was raging clear beyond all expectations, and now had developed the alarming stage of running in instead of out. After a thorough diagnosis of the malady we traced the germs to that enthusiastic Miller over in Barrington, and promptly advised that the doctor be not allowed to cross the river. This was as promptly decided to be out of the question, as the doctor had a very strong mind of his own. From careful observations we should judge that the fever has yet a long time to run.

HARD CASE OF BEE-FEVER.

DR. MERCHANT'S APIARY BY THE BAPTIST CHURCH.

Dr. Merchant is an active physician, with a large and lucrative practice. His apiary is located in his back yard, and it has a splendid backing in the form of a Baptist church. It is in the center of the town, and is not a nuisance to his neighbors or to the church-going people. The field here will sustain only about twenty colonies, and the doctor has accordingly a little less than that number. Like all down-east Yankees, Dr. M. is very ingenious; and every thing in the yard and in the hive is as near perfect in construction as possible. The hives and crates were of the cabinet-shop order in nicety, and many problems have been patiently worked out here. If the problem is found to be a hard one, he just thinks it out or goes over to Barrington and gets another addition to his bee-fever by thinking it out with Bro. Miller.

MR. MILLER AND DR. MERCHANT THINKING IT OUT.

The closed-end Hoffman frame is used with wide top-bars, and here we again saw the crates and honey-boards come off with not a brace-comb between. Aside from the frame, the hive was an invention of his own, and was provided with a side-opening feature, allowing the use of division-boards for contracting the brood-chamber, and allowing spaces on each side for the cork filling, which the doctor found an effective method for wintering. For summer use, the supers are provided with an extra cover, and the wintering cover is turned back against a proper support—in this case, a fence. This plan allows storifying to any extent. We find the practice here is to get one crate of sections nearly filled, then raise them and insert under a half-depth extracting-super. The photo of the hives by the church shows this plan of working, very clearly.

Dr. M. was quite enthusiastic over Alley's drone-trap. Being away from home at all hours of the day, dispensing pills and powders, traps are applied to every hive liable to swarm, and thus far they have been a success in preventing the loss of valuable queens.

Dr. M.'s crate was a little different from any we ever saw, and several points about it struck the Rambler very favorably. We were in hopes to give your readers a sketch of it in connection with this ramble, and will promise to do so as soon as we receive a sample crate from headquarters.

Prof. Cushman's large exhibit from the Experiment Station gave us a desire to visit him at Kingston; and though we were cordially invited to do so, our time was limited, and we had to refuse this and several other invitations.

While in Warren the Rambler had the pleasure of visiting with the doctor the town of Swansea, Mass., and the ancient home of our ancestors. The Rambler's grandfather emigrated from Swansea to York State about 1795; and the old homestead, about 185 years old, where four generations of our ancestors had lived, was still standing. Near by was the family burying-ground, now sadly neglected; and as we tried to decipher the moss-covered inscriptions, how forcibly the following lines came to mind!

> They died—ah! they died—and we things that are now,
> Who walk on the turf that lies over their brow,
> Who make in their dwellings a transient abode,
> Meet the changes they met on their pilgrimage road.
>
> 'Tis the wink of an eye; 'tis the draught of a breath
> From the blossom of health to the paleness of death;
> From the gilded saloon to the bier and the shroud—
> Oh! why should the spirit of mortal be proud?

Rambler.

FULL SHEETS OF FOUNDATION, ETC.

ARE WE USING THEM TO EXCESS? THICK TOP-BARS.

After reading a good deal about the thick (or heavy) top-bar, in which Ernest seemed to take considerable interest, and after using the light ones for some time and being bothered by their sagging down and getting frames and combs out of shape, I ordered 300 frames in the flat, ready to nail. The top-bars were to be ¾ inch thick, bottom-bars ½ inch thick, and the ends the same as the last named; and when they were nailed together they made a frame that was strong and durable, and hard to beat, in my estimation. Such a frame, made like the above, with a full sheet of foundation well wired in, when once drawn out by the bees makes a beauty of a comb. I consider foundation indispensable to the bee-keeper; and for the last few years I have used full sheets in all of the frames that I use, both for lower hives and surplus box (or extracting-box). These are well wired in, so there is no chance for sagging; and I am fully convinced that it well repays the bee-keeper to do so every time, although it costs him considerably more just then.

I really believe there is more benefit derived financially to the bee-keeper, from the excessive use of comb foundation, than any other thing he can use about the apiary. And I must say, I have not been so surprised in the last five or six years as I was to read what friend Hasty said in regard to foundation, page 33, where he says, "If the truth were generally known, the sale of foundation would be greatly reduced." Now, if such were the case (although I can't see it in that light) I should be very much obliged to friend Hasty if he would explain through Gleanings wherein there can be less used, and at the same time be as much of a benefit, in a financial way, to the bee-keeper, as though it were used still more extensively than at the present time. By using whole sheets of foundation the apiarist can control his brood-rearing mostly to his own liking (for there are not many of us who make it our business to raise drones), at the same time running for extracted honey. I would ask you all, What is there more perplexing to the bee-keeper, when he is running exclusively for extracted honey, than to now and then find combs filled with brood in the surplus boxes, where he expected them to be filled with honey? Now, if they are drone combs, the space so filled is worse than a dead loss. But, on the other hand, if all are worker combs so filled, they can be taken to some weaker swarm and put in their hive, and strengthened.

Some time ago, before I purchased some of A. I. Root's queen-excluding zinc that I used to keep the queen from going up in the upper story, I made some fine swarms artificially by having all worker combs in this way: My hive and surplus box hold 8 frames each; and when

I found in the surplus box from four to six combs well filled with brood I would set it off and remove the old hive to a new stand; then I would take a new hive (empty of course), and transfer the eight frames from the surplus box into it, and place it on the old stand, not caring which one retained the queen, for one *had* to be queenless.

There are very many more good points in favor of the excessive use of comb foundation; and it is a subject that is often brought up at our conventions, and fully discussed, and I for one have yet the first time to hear any one claim that we can get along just as well without it. BENJ. E. RICE.

Boscobel, Wis., Jan. 6.

BEE-KEEPING IN TUNIS.

ANOTHER LETTER FROM P. H. BALDENSPERGER.

When I first landed in Tunis I had to put aside the impression which I had always had in regard to "Afric's sunny fountains," for I had to put on every warm bit of clothing. It is true, it was the beginning of November; still, about the same time in Palestine we are generally suffering for want of rain, which was the case this year again, while in the North of Africa, Tunis and Algeria have had a great deal too much.

Owing to the want of vegetation in the immediate vicinity of Tunis (town), very few bees are kept. I have seen only a few flying about the sweetmeats one finds in all Oriental towns, put before the public on large trays, in front of the shops. Always accustomed to see the yellow Easterns, the sight of those black ones excite my curiosity. I had been told to look for bees on the other side of the gulf of Tunis. A small sailing vessel took me over in a couple of hours. On the point of the cape, and commanding the entrance, covered by divers destructions, lies the once mighty rival of Rome, so thoroughly destroyed. Seldom did ruins affect me so mightily as those of Carthage. Though in Palestine ruins abound, yet this ruler of the Mediterranean makes you feel that we are all but dust. The archbishops of Algiers and Carthage have built a beautiful cathedral on the ruin; and from the ruins in the excavations, beautiful marble statues and columns have been brought to daylight, showing the art of this ancient place. Thousands of olive-trees on the surrounding mountains make the scenery more beautiful.

The Tunisians keep numbers of bees out in the country, and they themselves also consume a good deal of honey, as the Mohammedans do not use any alcohol nor any preserved fruits in tins. They are fond of dark honey, and do not take very much to white or light-colored honey.

All over Algiers and Tunis the bees are kept in hives made of wickerwork, where willows, pomegranates, and such trees abound. The hives are long and square, made out of fennel-stems where those abound. These fennel-stems are about ten inches long, fastened together by passing a stick the whole length of the stems, placed sidewise together, and thus the four sides are again fastened together, the hive being about 3 feet long. They place them on a log of wood to keep them from the immediate dampness of the soil. The hives are smeared over with manure and sand, only one row at a time being placed beside another. The hives are again covered with straw, to keep them from the heat and the rain. The next row is placed in front, a few feet apart. They have generally one or two swarms from a good hive in April and May, and they take out the first honey chiefly from wild clover, etc. Later on, in favorable places they have a second crop of carob, thyme, and other aromatic plants. In some regions the rosemary abounds. There are also orange-groves; but up to this time they know nothing about orange-blossom honey, as the greater part of the apiarists are Arabs, going on in their primitive fashion. In Algeria they seldom or never move their hives expressly for pasture; but as the country people are all nomads they now and then are obliged to move the hives with the general move of the tribe.

The North African bee is about the same in color as the Maltese—black, with yellow fuzz. They seem to be a good honey-gathering bee, very prolific, and less inclined to sting than the Eastern bees. They are great robbers, but, as a rule, are not so active as the Easterns in attacking, and defending themselves and hives both against men and bees. We were transferring some hives a few days ago from a box hive into the bar frame; but no sooner had the bees smelled the honey than on they came, rushing, robbing away, and beginning to sting a little bit too. We could transfer only two hives at a time. The Palestines, though fierce robbers, would have left us in peace for at least four or five hives, but would have then been very ugly toward us too. The queens of this black race are not so easily found as our Easterns, as they differ much less in color. This queen is dark brown, and at this time of the year a good deal smaller than she is in spring when she is laying away with all her might.

Like all the Eastern nations they know very little about queens, drones, and workers. They believe that the bees gather the eggs from the flowers to produce young bees; or, again, that the queen is simply reigning and giving orders while the workers are really the mothers. They have a great veneration for bees, as the Koran tells them they are holy animals. On this belief a certain tradition is current among the Algerians. A young barbarian, Joussef Ben-Taschefin, succeeded, in 1036, to the throne of the last fatimite khalif of the Maghreb Abu Bekr. This Joussef was the founder of the Almoravides (European corruption of the word *Almorabith*—the priests—now corrupted into French as Marabut.) The father of Joussef was a potter, and was wandering about in the gorges of the Atlas Mountains to sell his wares. His wife followed him everywhere, carrying Joussef on her shoulder, as is the custom. A swarm of bees settled on the head of the boy. Astonished at this, the parents set to counting the bees, and found a hundred. They immediately knew it was some extraordinary event, and asked a divine (*talebu*) of great renown. The divine now explained to them that the will of God very clearly manifested itself, and that this child would become great, and reign from the Occident to the Levant; that he would have a glorious and long reign, and that each bee represented a people, and the swarm the whole of the nations united into one under his hand to form one large empire. He became lieutenant of Abu Bekr, who confided to him the command of the *Lamptunes*, a mighty tribe. Joussef took Fez and Mequinaz, the khalifat of the Edrissites, at the head of 80,000 horsemen, then marched toward Themcen, and subdued all to Beni-Mezegrena, in Algeria. After his return he founded Maraquesh (Morocco), and was thus prince of Morocco and the greater part of Algeria; but, unsatisfied with this, he succeeded in subduing all the north of Africa to Egypt. He then took the title of "Prince of the Musselmans and Defender of the Religion." Arab chroniclers say he built a vast bridge from Africa to Europe across Gibraltar, and took Mohammed-ben-Abd, ruler of

Mohammedan Spain, prisoner, without one single lost battle. Joussef died at the age of a hundred years, exactly the number of bees that were counted in the swarm.

The Arabs are very fond of honey, and this is a great cause why Algeria does not export a great deal. Here, also, they have manure to make the hives. The only time they visit the bees is to take out the honey, which they put in earthenware trays, and then press out the honey, simply by forming a ball out of the honeycombs and squeezing it out as fast as possible. Comb honey is never kept for sale. Some fine comb may be had if ordered beforehand. The wax is purified and brought to the market. In the Kabyly Mountains are the Kabyles (a different race altogether from the Arabs, for they are fair, and have a different language). They are very likely descendants of the Vandals, and may even have been Christians before Mohammedanism reigned here. The women of this tribe have a cross tatooed on the forehead, some also on the cheeks or chin—an old tradition they have probably carried through for centuries. These Kabyles are a good deal more industrious than the Arabs; have divers arts, as soap-making, pottery, and others. They live in stone houses in their wild mountains. Their women are unveiled, and they have a kind of shoes or boots made of cloth, resembling very much the old Germanic warrior's or Roman's foot clothing. They move their bees, too, to better regions when they find a good place of pasturage. Their land is better cultivated than the Arabs', and they raise a good many olive and fig trees. They are as fanatic Mohammedans as the Arabs, and in 1871 they were the fiercest rioters against the French, massacring all Europeans they could get hold of till the regiments coming back from Prussian captivity immediately checked the insurrection. The punishment has been very severe, but they learned to support the easy French yoke, and are even glad to call themselves French as soon as they are away from home.

PH. J. BALDENSPERGER.

Algiers, Africa, Dec. 18.

[Friend B., your legend about the little swarm of bees (just 100) reminds me vividly of my early days in queen-rearing. I had a great number of little hives with three or four combs three or four inches square. Well, when these little nuclei got their hives full they would swarm out; and swarms of bees, about as large as a goose-egg, got to be such a common occurrence during the height of the honey-yield that they were the sport of the neighborhood; and a queen with perhaps a hundred bees was likely to alight almost anywhere or on almost anybody, so that it is quite likely that so much of the legend was absolutely true.]

KEGS INSTEAD OF SQUARE CANS.

WHY A COMMISSION HOUSE PREFERS THE FORMER.

We note the discussion regarding the 60-lb. can, and the use of the same for extracted honey. As a rule, they are used exclusively in California; and all the honey we receive from there is put up in these cans, two cans in a case. This fact is generally known among the trade; and when they order California honey they expect to get it in these cans. For basswood, clover, and buckwheat honey, we have always advocated and advised the use of kegs holding about 150 to 200 lbs., or half-barrels holding about 300 to 350 lbs. We believe these packages are generally used in this State, Michigan, Wisconsin, Ohio, and Illinois. We receive large quantities from these States, and have always received it in kegs or half-barrels, and sometimes in barrels, holding 500 lbs. For our market we favor the use of kegs, half-barrels, or even barrels, because these packages find ready sale, and our trade prefers them. Besides they are less expensive, and cheaper for the producer than the tins. We can not advise the use of them when there is absolutely nothing gained. Honey in kegs, half-barrels, or barrels, will sell just as readily, and at as good a price, as when packed in tins. The same may be said for Southern honey. Kegs, half-barrels, and barrels, are the packages our market demands for extracted honey, with the exception of California.

HILDRETH BROS. & SEGELKEN.

New York, Jan. 10.

[Square cans *must* be used in California because the climate there will shrink the wooden packages; in fact, kegs would be utterly useless with them. We have always advocated the tin cans for *all* sections of the country, but perhaps there are good reasons why kegs should be used instead in this part of the U. S. They are easier handled, and, in some cases, can be shipped on a lower classification. While square cans will not shrink they are liable to spring a leak if the boxes in which they are put are too roughly handled. Kegs are stronger, but they also take more storage room, and, worst of all, they are very apt to give the honey a slight taint of the wood, which clean tin cans never do. In fact, the principal reason why we have abandoned the use of barrels and kegs is, we have so many times had a very fine article of honey so tainted by the barrel as to make it second or third quality. We should be glad to have bee-keepers and other commission-houses give us a little more light on this subject.]

CLOSED-END AND HOFFMAN FRAMES.

A WORD ON THE OTHER SIDE.

Friend Root:—As closed-ends, thick top-bars, and burr-combs seem to hold first place in the bee-journals at present, I feel it my duty to add a few words; first, because I fear some articles (written in good faith) are misleading; second, with so much testimony on one side, and little or nothing on the other, it may lead some to discard their convenient, well-proportioned frame for something they know little about. Of course, one who has had experience in bee culture will not be easily lead into changes; but the beginner, who is reading, and being guided by the teachings of the various bee-journals, often makes changes which his means will hardly allow.

I have had six years' experience with closed-end or one-half-closed-end frames (the original Hoffman frame), and have worked them nearly all out of the apiary. When I say six years, I mean I used the Hoffman frame exclusively that length of time. Exact spacing, by using a fixed distance or closed end, will work nicely so long as we take pains to have each frame in its original place and position. But we want our frames all interchangeable; and when we can get every comb perfectly straight and true, then we can use closed ends and be well pleased with them. But in our experience, combs *will differ.* We can not keep every hive exactly level at all times, and that of necessity throws our combs a little out of true; and I find that many combs, when changed from their original position, we have to change the bee-space at the top to get the right distance in the center of the brood-nest. Now, it will often happen that our ends are left $\frac{1}{16}$ of an inch apart, or we can't get them quite close enough. If left apart, the bees immediately fill the space with bee-glue; and after repeating this a few times, the apiarist will have to stop manipulations, and scrape bee-glue before his frames will fit and give the proper bee-space.

I have used the hanging frame, made of ⅞ lumber, top, sides, and bottom; and from actual experience I am fully satisfied they are far superior to a closed end in many respects. Before discarding (four years ago) the closed ends I experimented with colonies of equal strength and working qualities; also with the two frames in the same colony; and every time the hanging frame gave the best satisfaction. There are many reasons I might write why I favor the hanging frames, small in themselves; but bee-keeping is made up of small things; and he who overlooks the small things will come far short of being successful in this world, whether it be bee-keeping or other business matters.

In regard to burr-combs, I have used both thick and thin top-bars, and can see no difference. I am of the impression that burr-combs are due largely to the race of bees, and the right bee-space above the frames. I find with me that ¼ inch, scant, is about right, and with that bee-space I should prefer a frame just heavy enough to prevent sagging, as I like to get the sections just as near the brood-nest as possible.

A. E. Woodward.

Grooms Corners, N. Y., Jan. 12.

[I am glad to get your testimony, friend W.—not that it proves that the closed-end or Hoffman frames are impractical for the *majority* of bee-keepers, but because it shows that there are *some* bee-keepers like yourself, who, after trying them, would discard them for the hanging frames. Bee-men can not all be induced to use the same kind of frame, by a long way; and, if my judgment is worth any thing, I should say that neither the loose hanging nor fixed-distance frame will be used exclusively. Both will be used, and have their firm adherents. But your testimony, friend W., is diametrically opposed to that of a good many bee-keepers whom I know—those who have tested both the fixed and the unfixed, and have finally decided most emphatically in favor of fixed frames. I feel pretty sure that the difficulty you speak of, about combs not being interchangeable, must be due to some fault in your manipulation. Capt. Hetherington, Mr. Elwood, and Mr. Julius Hoffman, do not experience this trouble—to say nothing of the hosts of the smaller following. While I watched Mr. Elwood manipulate his frames, he alternated them as much as you and I would the loose hanging frames; and, remember that these gentlemen own something like an aggregate of 5000 colonies. There is a great deal in getting used to a thing. Although your article above shows that you have had considerable experience with fixed distances, there is possibly some factor that does not appear on the surface, and yet nevertheless is the cause of your trouble. Perhaps Mr. Elwood will enlighten us on this point a little, later on.

In regard to thick and thin top-bars, your experience is also diametrically opposite to our own, as well as to that of a good many others who have sent in reports. It is one of the *strange* things in bee culture, why good competent bee-keepers should have experiences so different, and it is not much wonder that it does confuse beginners. Mr. A. says he has had such and such experiences with a certain device. Mr. B. has had just the opposite. But that does not prove that the article in question is valueless.

You are correct about the right bee-space. It should be a scant quarter inch, and, by the by, this *may* explain why you say you see no difference between the thick and thin top-bars. This small bee-space, I know from experience and observation, makes a good deal of difference in the matter of burr-combs.] E. R.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

WHY THE QUEENS WERE CARRIED OUT.

I introduced two queens into hives in October. In about a month after they had been introduced I found them both in front of their respective hives, almost lifeless. They were straight and plump, but their bodies were not distended. The colonies had natural stores and granulated-sugar syrup. The queens were reared elsewhere. What could have been the trouble? J. C. Atkinson.

Nelsonville, O., Nov. 28.

[No one can give the reason, any more than to conjecture; but my impression is, there was a queen already in the hive when you introduced one; and if you are only a novice, friend A., I should not wonder if they were not queens at all, but simply bees with elongated bodies. I once mailed such a bee to father Langstroth, saying that I had lost my twenty-dollar queen. But I was greatly rejoiced when he wrote back that it was not a queen at all, but only the body of a distended bee. I found it outside of the hive, as you did, and warmed it up, and it came to life a little.]

SECTIONS SOLD BY THE PIECE; WIDE AND THICK TOP-BARS A SUCCESS.

I have been back East through York State and Connecticut. I have read about selling sections of honey by the piece. Now I will tell you about what I know. I sent 823 lbs. to Connecticut. I had one crate of 15 boxes, of 12 lbs. each. It was hard work to get rid of them, as they wanted about 10 lbs. to 12 sections. I did not find one man that sold honey by net weight, always by the section.

I have tried seven different kinds of brood-frames. The best I have tried is with top-bars 1⅛ in. wide and ⅞ inch thick. They give the best results, for there are no burr-combs between frames. I space just 1⅜ inches from center to center. I will take wide and thick top-bars every time. A. N. Whitlock.

Dover, Mich., Dec. 15.

WINTERING IN AN OUTER CASE A SUCCESS; A DEAD-AIR SPACE SATISFACTORY.

I never could see why burlap or cushions were better above the brood-nest than a board that the bees could seal down air-tight, or why sawdust-packed hives were better than double-walled hives with a dead-air space. I winter on summer stands, and still have five different hives for experiment. The hive I principally use is the Heddon (for want of a better) with an outer case of ⅞ lumber. In these hives I rarely lose a colony (I lost one out of twenty in three years). If I should happen to loosen the cover after being glued, I use a paste to make it tight. My bees breed up fast in the spring, and are ready for business when the honey-flow comes, and I always get the best-ripened honey from those hives, selling my honey as fast as taken from the hives, in my town.

In experimenting with double-walled hives, a hive with a one-inch dead-air space all around it is warmer inside than a hive with space packed. The same is cooler in summer. What has become of the ventilation theory? I settled this theory in a few words. Why do bees seal down the cover air-tight if they should have ventilation? J. T. FLETCHER.

Clarion, Pa., Dec. 8.

DO DARK COMBS AFFECT THE COLOR AND QUALITY OF THE HONEY?

The question, "Do dark combs affect injuriously the color of honey they contain?" was, I believe, answered in the negative at the Keokuk convention. I believe this answer to be correct, if the honey is allowed to remain in the combs but a short time. But if allowed to remain in such combs a few months, its color and flavor are both very perceptibly impaired.

A year ago last March I warmed up and extracted several gallons of Spanish-needle honey for a neighbor from combs that he had taken out of upper stories in the fall and stored away in his house until he could get some one to extract them, as he had no extractor. The combs were not particularly dark, yet the honey was decidedly off in flavor and color when compared with my own honey gathered on the same range, but extracted as soon as well ripened. T. P. ANDREWS.

Farina, Ill., Dec. 20.

OUTSIDE SHOW, WITH THE INSIDE NOT IN KEEPING.

Friend Root:—I have seen a little of the same kind of work you speak of, putting the best on the outside, or on top. You are doubtless aware that Utah has had a good reputation for the quality of *potatoes* produced, but perhaps you are *not* aware that her good name has been greatly injured by this outside-show business. Now, I will omit names; but Mr. B. being a business man, and in the shipping business, and having a reputation for square dealing, receives numerous applications for those noted potatoes. Mr. B. goes among the (honest) farmers and tells them what he wants, and will pay so much a bushel for them, sacked and loaded on the cars. Now, probably there are half a dozen men loading a couple of cars. A few of the sacks are opened in the hurry, and fine potatoes are seen on top, and very likely five of the six men have been honest, and put just as good ones all the way through; but the sixth one is the Judas; and as the sacks are loaded promiscuously, without being marked, all must bear the blame of those small and some frozen and inferior potatoes. The shipper, of course, is held responsible; and when he has trusted too much to the honesty of the producer he "gets left." Can anybody say this is right? I for one am not sorry that friend Root is starting in to let the blame fall on the shoulders where it rightfully belongs, and not on the innocent, notwithstanding it may "cut close." And I think ninety-nine out of every hundred of your ten thousand subscribers will be willing to stand by you; for when a man or woman has labored diligently for a good reputation it is not pleasant to have it tarnished by Iscariot.

I think you are right when you think each package of honey must have its producer's name on it. Although we are a brotherhood of bee-keepers, and could, and perhaps should, work more for each other's interest than we do, still, until we become a little more perfect, we shall have to look to ourselves for a good name. In fact, that same little individual self is one that we must keep watch of, for he is probably as liable to go wrong as any one.

Taylorsville, Utah, Dec. 9. HOMER BROWN.

A KIND WORD—ROAD-MAKING, ETC.

Mr. Root:—I have read with great appreciation your article under the head of "Myself and My Neighbors," in your Dec. 15th issue. In this new country I see so much shiftless management, and hear so much complaining about railroads and banks and monopolies, and big crops and low prices, and big prices and no crops, to all of which your remarks are so pat, that I feel like responding, as I once heard an earnest listener in a Methodist church. He sat close up under the pulpit; and as the minister clinched every argument he was ready with a response, as is quite usual in that denomination. Finally, as a still more profound truth was uttered, he shouted out, "A—men! true as preaching!"

Apropos of your illustration about the way road work is done, don't you think that people who work, particularly farmers, need, above every thing, to learn and act up to the old maxim, "Whatever is worth doing at all is worth doing well"? To use a current slang expression, it makes me "tired;" yes, very tired, to see the way, when a low piece of ground is to be piked, they will go into the very lowest spot and plow deep holes on each side of the road in order to get dirt out of which to make the embankment. There is an old saying, "Let well enough alone." I could never see any sense in it; but too many interpret it in this fashion—that, when a thing is done so as to answer for the time being, it is done well enough. As you say, what a vast amount of time, labor, and money is wasted by doing things over year after year! Every one seems to be striving, not to do as well as he can, but to do as *much* as he can. The other day a man came to me and asked if I knew of a farm to rent. I suggested a place, a good farm containing eighty acres. No, that wouldn't do—there wasn't land enough. Just think, of it! only himself, no boys to help him, one team of horses, and eighty acres wasn't enough. He must have one hundred and sixty acres to scurry over. Yes, indeed it does make one "tired." HORACE N. JONES.

Clay Center, Neb., Dec. 22.

BOARDS OR QUILTS: WHICH ARE BEST TO COVER SUPERS?

Until the present season I have always used quilts placed directly on top of the sections in the super. More and more I became dissatisfied with them, because of the great masses of propolis put between the sections and quilt. Sometimes the quilt was shoved up enough to let the bees pass over the sections, and the whole top of the sections was smeared with glue.

This season I handled 125 colonies in two apiaries, run for comb honey only, and all in ten-frame Simplicity hives, slatted honey-board, and Miller T super. On about half the colonies we used the quilt to cover the supers. The rest we covered with board covers, just a plain ⅜ board cleated on top to prevent warping.

With the super holding 28 sections we have on top 32 openings, every one of which will be lined with propolis, making 16 ft. of line propolized; but with the board we have about 12 ft. of line propolized; viz., the outline of the super, 5 lines across between row and row, and row and super, and a little at the corners of the sections, where they touch the super on the side of the super. The board being rigid, it is simply glued down; but the quilt, being flexible, is crowded up, consequently receives two to four times as much glue, and is stuck right on top of the sections, which, when scraped off, have a streaked, motley appearance, while those covered with a board will be somewhat discolored all over the top, and have just a small line of glue on each upper corner, to knock off. The whole top of the section being slightly discolored, it looks better than the spotted one. The heat will rise to the board, and equalize much better than with quilt.

COMB HONEY SOILED BY PROPOLIS.

We seldom had less than two supers on each hive, and sometimes four and five, and had frequent occasion to interchange, putting the top super down, or else putting a new one on top of those already on. Now, those, being covered with quilts, when placed below, must have those great piles of propolis scraped off, which takes up much valuable time, and, when done, will have to be smoothed down by the bees. This extra glue that the bees smooth off must go somewhere, and much of it goes into the cappings of the honey near its location in the super. Some will think it is only travel-stains. Even if it were, we don't want so much glue tramped in our nice white combs. But careful observation, in many instances, showed great spats of this extra glue placed right on the combs.

Fort Collins, Col., Dec. 24. R. C. Aikin.

SPRING DWINDLING—A GOOD SUGGESTION AS TO ITS CAUSE.

I have not seen the subject of spring dwindling explained as it has occurred under my observations, which are these: Once in three or four years we have a late flow of honey, mostly from aster; and the bees that should (and, under ordinary circumstances, would) live until others appeared on the stage in the spring turn out and work early and late after the weather has become so cool that one is surprised to see them out, in consequence of which many die through the winter, whether wintered in the cellar or outdoors; and when commencing work in the spring they die off like "old sheep" before others can be raised to take their places. The result, many know to their sorrow. Well, what is the remedy? I wish I knew. Feeding to keep up brood-rearing after the close of the surplus season would be all wrong when the late honey failed to come. Some stocks with young queens keep up brood-rearing late, and get through all right, when, if the late flow had not come, they would require heavy feeding sometimes, while the others would be in much the best shape.

Bartlett, O., Dec. 15. E. S. Fowler.

[It is well known that spring dwindling does not come every spring; and as it appears irregularly, your suggestion is a good one—as good as any that have been given. Has any one else observed that a late honey-flow is apt to be followed by more or less spring dwindling?]

AN EXPERIMENT WITH HAIR FOR PACKING.

I am trying an experiment this winter with four chaff cushions filled with hair, such as is used for plastering. Our folks run a tannery, and they are troubled with bumble-bees building nests in the hair-house, and I think honey-bees will not be offended if we fill their side-walls with good dry hair. Of course, there is some lime in it, but that will absorb some of the moisture from the hive, and become dry again without rotting, as chaff will. I will send you free samples, large enough so you can fill four side cushions. We use the Falcon chaff hives.

Mrs. J. W. Brodie.

Warsaw, N. Y., Dec. 1.

DOUBLE-WALLED AHEAD OF SINGLE-WALLED HIVES; THICK TOP-BARS A SUCCESS.

We got some honey from all of our chaff hives, but there was not a pound of surplus from the single-walled hives. We used heavy top-bars this year, $\frac{7}{8}$x$1\frac{1}{16}$, and there was not a spoonful of wax on the top of about 200. I like them much better than the light ones. We used the T super over them without any honey-board—put a strip under each end of the super, and there was no wax nor brace-combs to bother.

F. L. Hankins.

Blandinsville, Ill., Dec. 8.

A GOOD REPORT FROM THE HOFFMAN FRAME.

The past season was entirely too wet to be very favorable to the bee-keepers of New Jersey. My honey crop this year is slightly over 1600 lbs., all but 150 of which is comb, from 60 colonies, spring count. Clover sold at 17 cts., and buckwheat at 15—better prices than for some years past.

In speaking of the Hoffman frame, when, in 1885, I bought the apiary of my brother, John B. Case, now of Port Orange, Fla., he was using both kinds of frames, the Hoffman for experiment, with gratifying results. Now, if any one will use both styles, Hoffman and common, not only in the same yard, but in the same hive, as I have done, I think he will very soon discard all but the Hoffman. They can be handled just as rapidly as the common, and spaced in a flash. A good way to test the matter is to put, in a hive, half of each kind of frames. There are but few other kinds of frames used in this section at present, and they are imported from New York, Ohio, and other foreign parts. I should almost as soon think of going back to the old box hive as to give up the Hoffman frame.

There is a hive manufactured not more than a thousand miles from here, in which the frames are permanently spaced; i. e., nailed in fast and tight; and some declare, after using them, that they can not see much difference between a frame hive and a box hive. Strange, isn't it? W. W. Case.

Baptisttown, N. J., Dec. 29.

[Thanks for your very valuable testimony. Comparative tests are what we want. In only one instance that I know of was the Hoffman frame adopted and afterward discarded. In this case it was not for the hanging frames, but for a frame still more fixed—the closed-end Quinby. I feel morally certain, that, where a fair comparative test is made, like the one referred to above, the Hoffman will come out ahead in nine cases out of ten. The man who shuts his eyes to these improvements, and won't try them, is the one who will be the loser in the race, in the long run.] E. R.

WHY L. FRAMES ARE PUT LENGTHWISE OF THE HIVE.

Friend Root:—Why do you and most of the bee-men, so to speak, advise the frames being hung lengthwise instead of across the hive? I ask for information. It can't be so warm in winter, and I should think they would be more difficult to handle. C. H. Peabody.

Providence, R. I., Dec. 18.

[This matter has been pretty thoroughly discussed in times past, friend P. The L. frame is always used running from front to rear, or pretty nearly always. Where the entrance is the whole length of the front, a bee coming in from the field can go between any two frames in the hive, without passing over any. In very hot weather, the air coming in at the entrance can also go between all of the combs. In handling the combs, the operator naturally stands at one side or the other of the hive, and never in front, so as to cut off bees from getting in any of the entrances. If we wish to divide the hive by a division-board, so as to make two or more colonies for queen-rearing, the entrance is readily divided, without the necessity of cutting new entrances in any of the hives. Other reasons may, perhaps, be given. Very likely there are other reasons besides the one you mention for having the frames go crosswise.]

OBJECTIONS TO BENT-POINT WIRE NAILS FOR WIRING.

Last season I tried the wire nails in wiring brood-frames. I don't like the plan of bending the points, as they do not make a neat job, and it takes considerable time also. I have a plan that seems good if we can get the nails made that way. It is, one-inch wire nails with eyes punched through about ¼ or ⅜ inch back from the points. Iron wire nails would do, or nails somewhat flat; or, how would nails with beards cut a little way back from the point do? What would the first-named cost per lb.?

Nye, Ind., Dec. 29. C. A. Bunch.

[Friend B., the only way to get a nail with an eye in it would be to get up the machinery and make them. The nail companies would not take it unless an immense order were given them. There is no nail in the market with a barb long enough to catch the wire securely. A barb would be much handier than an eye, for the wire could be hooked over it. I am inclined to think that hooking over the point would be the cheapest way at present. If you use a very slender nail, and have the right kind of round-nose pliers, it need not take very much time.]

CLOSE SPACING A DECIDED ADVANTAGE.

I have read Mr. Boardman's suggestions in December 1st Gleanings. Our hives are the same kind as those used by Mr. B. Three years ago next spring I put an extra frame in the few hives we then had, and have continued to do so. Our bees have done splendidly, wintered well, and we are scarcely troubled with burr-combs. I think Mr. B. will find the extra frame quite a help to him. We had a good yield of surplus honey the past season, and the hives were very heavy when we put them in the cellar for winter, about Dec. 1st.

JAPANESE BUCKWHEAT—50 BUSHELS PER ACRE.

In regard to Japanese buckwheat, here the past season it has shown its superiority over the old black variety. While many pieces of the black were badly blasted by three or four hot windy days, the Japanese was scarcely affected at all. We had fifty bushels to the acre. Several of our neighbors who came to look at it said it was the nicest piece they ever saw. B. T. Scothan.

Rogersville, Mich., Dec. 24.

[These are the kind of facts we like to get. Close spacing has only to be carefully tried to prove its advantages.]

THE MODIFIED HOFFMAN FRAME—A GOOD REPORT OF IT.

I acted at once on Ernest's suggestion (page 780), and changed the hanging frames of one hive into Hoffman frames. It did not seem to work right. I could not lift even two frames at once, so I pulled the spacers off and cut the top ends square, as on page 425; nailed them on, and they did better. I can lift three or four frames easily, and they work nicely so far. I also found there has to be a spacer nailed in one corner of the hive, and one on one corner of the follower.

My bees have done well this fall, and are in good fix for winter. The spruce pine has been in bloom over a month, and the bees are working on it every day. They are bringing great loads of pollen and some honey. I know they get pollen from the pine bloom; but do they get the honey from it too? J. H. Hill.

Venice, Manatee Co., Fla., Dec. 27.

[If you like extemporized Hoffman frames—that is, those made from common frames, you certainly will like the Hoffman made exactly as the inventor recommends. The regular Hoffmans are easier and more satisfactory than something fixed over.]

WHAT FRAME TO ADOPT—THE VAN DEUSEN OR HOFFMAN.

I have decided to adopt a fixed frame, and can not decide between the Van Deusen reversible and Hoffman. I suppose you have thoroughly tested both by this time, and I should like to know your preference. I think I should prefer the Hoffman if it were reversible. Do you think this much advantage, or enough to adopt the Van Deusen in preference to the Hoffman, regardless of cost? C. E. Layman.

Troutville, Va., Dec. 11.

[Both frames have their points of advantage. For a fixed frame we prefer the Hoffman. If you want the reversing feature this will not do, and you had better select the Van Deusen. The safer way is to try a few of each.]

JAPANESE BUCKWHEAT TOO LARGE TO GO THROUGH ORDINARY SIEVES.

What will you give for 30 bushels of Japanese buckwheat? The miller here thinks he can not well grind it, on account of its size.

Miss Libbie Williams.

Delavan, Wis., Dec. 24.

[The above and similar letters indicate unmistakably that the Japanese buckwheat is larger than the common. Tell your miller, that, if he wants to be up with the times, he should get a sieve that would accommodate the new buckwheat.]

HONEY LIKE WET SUGAR.

Our bees in this settlement this fall made honey like wet sugar. What is the cause? It never was so before. We have had the driest summer and fall we ever had.

Aumsville, Or., Dec. 12. W. W. Brooks.

[Friend B., such honey has been several times reported, and it almost always comes during a dry season or fall. We have had several reports from candied honey-dew from your locality—the kind that makes little balls of candy on the twigs of the fir-trees. As this candies on the trees, it would be nothing strange to see it candied in the combs.]

SPANISH NEEDLE.

I was visiting in Iowa during August and September, and I saw the large flowering Spanish needle for the first time. It is different from what we have here. Some of the flowers are two inches across the petals, and of a beautiful yellow color. I saw the bees at work on them. They are a different kind from what we have in Ohio. W. S. Imlay.

Zanesville, O., Dec. 8.

[Friend I., we are glad of what you tell us. One of the first things for bee-keepers to do during this coming season is to work up this great field along the Illinois and Mississippi Rivers.]

SUCCESS BY THE A B C OF BEE CULTURE.

I must tell you how well I succeeded with my bees with the help of your A B C book. Last fall I bought three ordinary hives, and did not know a queen from a drone. I studied the A B C all winter and this summer. I increased my bees to 16 good hives, and extracted 40 lbs. of honey, besides learning a great deal that I wouldn't take money for. I have bought enough to increase my number to 30 hives, and expect to do wonders next year in the bee-business. We have thousands of acres of alfalfa for pasturage; and although we live at an altitude of 7500 feet, our bees flourish.

Mancos, Colo., Nov. 10. **MRS. A. J. BARBER.**

THE NEW DOVETAILED HIVE WITH A FOLLOWER AND CLOSED-END FRAMES JUST THE THING FOR OREGON.

In the Dovetailed hive you have struck a keynote in adding the "follower and wedge" to key up the frames and sections. This keyboard (as I have called it) and wedge have been in use in my apiary for ten years, and are considered indispensable. I have used a section-holder during this time, made by nailing these same "inset slats" to ¼ x ½-inch strips, the same resting on tins as in the dovetailed super, but without the end pieces. This gives a vacant space of an inch or so at one end, which gives easy room for handling sections, and the follower holds all snug.

The Dovetailed hive, if wide enough to admit of, say, a half-inch division-board on each side, with closed-end frames, virtually making a double-walled hive, is just the hive for our Oregon and Washington climate, where it is never extremely cold, but where we have dampness to contend with. The heat from the bees will drive the moisture through this half-inch wall to the open-air space, where it will condense and run down out of the hive, leaving the bees dry—a most favorable condition for wintering successfully. **E. S. BROOKS.**

Silverton, Ore., Jan. 13.

FAIR RENTAL FOR AN OUT-APIARY.

As I have more bees than I think I should keep at home, I intend starting an out-apiary this season; and having had no experience myself, and as there is no one here to consult, I write to ask you what is customary or right compensation to pay the parties owning location, as rent, etc., for privilege. In other words, what arrangement is usual between the bee-keeper and the owner of the land?

Florence, Kan., Jan. 5. **T. J. CONRY.**

[Rental for grounds on which out-apiaries stand is usually rated at $10.00 per year. It is just as you can agree. A good many pay no rent: they make gifts of honey.]

MORE ABOUT THE NEW IDEA.

Friend Root:—I see, by the way you headed my article on page 25, that my New Idea was not well understood by you. It is not a wire-cloth cage in front of the hive, for wire is hard for bees to fly against—also a conductor of caloric, therefore not good, besides too expensive and cumbersome; neither is it mosquito-bar, as might be inferred, as the feet of the bees will entangle in it.

My bees are doing grandly under this treatment, and are less restless than those in the dark cellar. Among those placed upstairs, under protection of the new idea, was a colony, robbed on the last of September. I feed them in the New Idea, and every two or three days they have a grand festival and carry some stores into the hive. They well know where to find their rations; but it is wonderful how they assemble to enjoy their festivities.

During the month and twenty days that I have had these colonies upstairs, the dwindle is next to nothing, while those in the cellar can be gathered up by the quart. From present indications I am confident that the New Idea solves the enigma of wintering without loss; and if success attends until they reach the summer stand, upstairs will supplant down cellar, universally, in less than one decade.

The character of this device is a riddle not easy to guess, and I retain the knowledge to myself until success attends it, at which time I will send you a sample one, whereby the fraternity will be made to wonder at its simplicity.

Nirvana, Mich., Jan. 19. **F. D. LACY.**

AGAINST INCORPORATING THE BEE-KEEPERS' UNION WITH THE N. A. B. K. A.

On page 894, Dec. 15, Dr. Miller makes a proposition to merge the N. A. B. K. A. into the Bee-keepers' Union. I think that should not be done without the consent of a majority of the members of the Union; and as a member I wish to hand in "no" to the plan. I do not see where it would benefit the Union in any way, so I object to it. **E. D. HOWELL.**

New Hampton, N. Y., Dec. 15.

REPORT OF THE YEAR.

In the spring of 1889 we set out 80 stands of bees. During the year we increased the number to 200, which were all alive in the spring of 1890, but some of them were weak. There were 185 when the fruit-trees blossomed, and we were highly pleased with the prospect for the last year. We received over 7000 lbs. of honey from 80 swarms. For 1890 we received only about 700 lbs., and have only about 175 stands left. **R. H. RANDALL.**

Big Rock, Iowa, Dec. 20.

CALIFORNIA HONEY IN OLD OIL-CANS.

The honey is very rich, but I don't like it in oil-cans, for it spoils the flavor, for it tastes so strongly of the oil. I would rather pay a cent a pound more to have it in new cans.

FREDERICK HUND.

Casco, St. Clair Co., Mich., Nov. 30.

---

150 LBS. OF HONEY FROM THE BEST COLONY.

My bees have done fairly well this summer, my best colony giving 150 lbs. extracted honey. I had 12 colonies, spring count; increased to 22; sold one, and took 400 lbs. comb and 400 lbs. extracted honey from them, and left plenty for winter stores. **A. E. SNELGROVE.**

Camborne, Ont., Can., Dec. 13.

ALFALFA-ROOTS—HOW DEEP DO THEY GO?

On page 401, A B C, you intimate that the cut of the alfalfa-root is probably exaggerated. From an extended visit to Kern Co., Cal., this season, I can testify that the statement, that the roots reach a depth of 20 feet, is correct; and for feed for stock, it has no equal.

Maroa, Ill., Dec. 4. **F. D. LOWE.**

A REMEDY FOR BLACK ANTS.

My hives were covered with ants, and now I don't see them at all. The bottoms of my chaff hives are painted with coal tar. It cost 10 cents a gallon. One quart warmed and spread on quite thick, with a brush-broom, will paint the bottoms of 10 hives. The mice do not trouble them either. It is cheaper than tarred paper; besides, it preserves the wood. **R. A. TOBEY.**

Caton, N. Y., Jan. 6.

OUR QUESTION-BOX,

With Replies from our best Authorities on Bees.

QUESTION 177. 1. *When a cellar gets too cold, is artificial heat, such as that from a stove in the cellar, injurious? 2. If you think it advisable to use a stove, would you try to keep a steady heat, or warm up by spells?*

Warm up by spells.
Illinois. N. W. C. MRS. L. HARRISON.

I will let the cellar men answer this.
Wisconsin. S. W. E. FRANCE.

1. No. 2. Bring the temperature up to 40, or about, and then close the cellar and try to keep it at that.
Illinois. N. W. DADANT & SON.

1. Not if you are careful. 2. A steady heat, with facilities for turning it off in warm spells, would probably be best.
New York. C. P. H. ELWOOD.

1. I think that artificial heat may be used to advantage. 2. Warm up by spells, and then let the bees become quiet.
Ohio. N. W. H. R. BOARDMAN.

It is claimed by some, I believe, that the temperature of a bee-cellar should be between 45 and 50. The steadier your temperature, the better.
Ohio. S. W. C. F. MUTH.

1. No, but I'd try hard not to have it get too cold. 2. I would keep an even temperature; and a cellar that is fit to winter bees in may easily be kept warm enough with an oil-stove.
Ohio. N. W. A. B. MASON.

1. No. At least, it won't do as much harm as too much cold. 2. I don't know. I suspect it doesn't make much difference. If you could keep them just right, the steady is probably better. The occasional is easier.
Illinois. N. C. C. MILLER.

1. The temperature in a cellar should be maintained at 45°, as nearly as possible. I should prefer a good oil-lamp, rather than a stove, to warm the cellar, by coloring the chimney with smoke, or using a tin chimney, in order to exclude the light. 2. Keep up the heat, *a steady heat.*
Vermont. N. W. A. E. MANUM.

Not if very carefully managed; but great caution is imperative. I should prefer a uniform heat, so as to keep the cellar just about right; but I have no hesitation, as the temperature goes down toward freezing, in putting in a fire; but I carefully watch, and remove as soon as the temperature gets to 45°, or even up to 50°, if the weather is very cold.
Michigan. C. A. J. COOK.

From my practice I can readily answer that stove heat is not injurious; and the best way to do is to warm up by spells, unless you have a very large cellar, say under a building as large as a store. I divided my cellar with a board partition, putting the bees in the big part and the stove in the small one. The stove heat radiates through the board partition after making the little room and stone wall around it very hot. In this way I avoid excessive immediate heating of the bees.
Michigan. S. W. JAMES HEDDON.

My bee-cave needs no artificial heat. If I had a cellar which was too cold I would experiment with artificial heat to see if I could better it thereby. So much depends on the *man*, and his thorough or shiftless ways, that what might be a success with one might prove only a failure with others.
New York. C. G. M. DOOLITTLE.

1. While I have never tried warming a bee-cellar by artificial heat, I feel very sure it would do no harm, provided proper care were taken not to excite the bees by too much noise or light in caring for the fire; or if a smoking stove or an uneven temperature were guarded against. 1. By all means keep a steady, uniform heat when heat is needed.
Illinois. N. C. J. A. GREEN.

If a cellar had the habit of getting down to the freezing-point, I would first try to remedy the defect in the cellar. If I could not do this I would partition off an ante-room, and put in a coal-stove. The ante-room, though small, would shield the bees from direct heat and light, and secure an even diffusion of heat. I would keep a steady heat during the cold term, or during zero weather. The rise and fall of temperature would cause uneasiness.
New York. E. RAMBLER.

I have had very little experience with indoor wintering. Those who have tried it, I believe, mostly say artificial heat won't work. Not having tried it, it is easy for me to suspect it might be made to work if one would get at it just right. An uneasy owner might easily imagine his bees were suffering greatly from cold when a quiet letting-alone would bring them through all right. 2. Nothing succeeds like success; and nothing fails so miserably as failure. I suspect success could be had on either line; and failure on either line, I am pretty sure, could be had.
Ohio. N. W. E. E. HASTY.

1. Hard to tell. It has not been satisfactory with me. The trouble is to get the heat evenly distributed and keep it so. To do this it would require something in the furnace, steam, or hot-water plan of heating, and would require more of an outlay for fixtures than one would wish to incur, and more skill and patience to tend the plant than most of us possess. 2. I have a stove in my bee-cellar, and I have found it handy to dry out moisture before putting bees in, and to heat up honey to feed or extract where some is left late in the fall. What we should aim at in the construction of cellars is to construct them so that the heat of the earth and bees will keep them warm enough without resorting to fire heat.
Wisconsin. S. W. S. I. FREEBORN.

[I am glad to see so much of an agreement in regard to the above. In our locality—at least, as our winters have been for a good many years back—I feel certain that it does not pay to winter bees in cellars, all things considered; and if I lived where it is cold enough to warrant cellar wintering, I think I should follow friend Freeborn's concluding remark. In fact, I did it years ago, and brought them out in good condition. Now, then, comes the question, "Would they not have come out in good condition had they been left entirely alone?" I rather think they would, in the majority of cases. There are times, however, say when the bees have poor stores to winter on, when, by warming up the cellar occasionally by the aid of a stove, we get them through until they can be put out in the spring, where they would not have come through otherwise.]

MYSELF AND MY NEIGHBORS.

Your adversary the devil, as a roaring lion, walketh about, seeking whom he may devour.—I. PETER 5: 8.

We read in the Holy Scriptures, that "the fool saith in his heart, there is no God;" and I believe that all mankind, as a rule, assent to this proposition. It is only the foolish, or those who are stubborn and contrary, who absolutely *deny* the existence of any overruling power; and the attitude of the leading minds of the present age, if I am correct, is toward a more general belief in God than they ever have had before in any age. I believe the tendency is greater, also, to respect and reverence the Maker of all things in a way the world has never done before. It is true, there are those who take God's name in vain; and one is often pained to hear men of culture and learning use profane oaths. But I believe a reform is coming, and that speedily, right along in this line. Well, I have been thinking that it is not only wise to accept the Bible statement in regard to God, but that it is also wise and well for us to recognize and believe in one who "goes about as a roaring lion, seeking whom he may devour." The world is fully aroused in regard to dangers of different kinds that threaten humanity. Societies without number array themselves against intemperance; and some who declare they do not believe in the Scriptures at all are still energetic workers in the cause. It seems to me, however, through it all we should recognize that *sin* is really the one thing to fight against. The Bible is peculiar, inasmuch as it lumps all sorts of evil and iniquity under the one term—*sin*—and plainly designates Satan himself as the *father* of sin. I believe it is a good thing to recognize Satan as *the* adversary. I believe it is a good thing to recognize at once, when some friend or neighbor has gone to the bad, that he has come under the dominion of Satan. Like the rest of you I often hear certain ones vehemently denounced for their vile conduct. Sometimes I try to check those harsh words that come forth; and I then suggest:

"My friend, are you not *sorry* for this neighbor of ours?"

"Sorry? Why, no; I am not a bit sorry for him. He did it of his own accord with his eyes open."

"But he is under the power of Satan—he is not himself. He has been lead astray, and has yielded. While he may be greatly to blame, in considering how we may do him most good is it not best to recognize that it is *Satan's* work?"

"Satan! fiddlesticks! When one deliberately acts as he does, I do not think it is worth while to waste pity on him."

Now, these friends who reject my way of putting it (that it is just simply Satan's work), it seems to me are not in an attitude to do the most good; and we as *Christian people* often entertain this wrong attitude. Satan gets hold of somebody else, and leads him astray. In our indignation with the brother or sister, we let a wrong spirit get into *our* hearts, and Satan gets hold of us all if we do not look out. If he can get us to fighting intemperance or gambling, or lying and theft, he is much better satisfied than when he finds out that we recognize the *cloven hoof* in the whole matter, and denounce *him* as the father and author of *all* sin.

Only a few hours ago a good friend of mine, and a devoted Christian, dictated an answer to some one who showed a wrong spirit in discussing accounts. I carried the letter back to her and said:

"You know this good friend of ours who writes this letter, do you not?"

She assented.

"Well, you do not wish this answer sent to her, do you?"

"But indeed I do. It is just exactly what she *deserves*."

"But is it the kind of answer that will do her the most good, and be most likely to get her out of the wrong position she seems to have taken?"

"No, Mr. Root," hesitatingly, "I do not suppose it is. I *do* know that the best way in answering anybody is to strive to use such words as will do them the most good."

An answer was then dictated in quite a different spirit.

Now, instead of blaming and censuring these neighbors of ours when they do wrong things, will it not be far better to lay at least a *part* of the blame on Satan, the author of all mischief? And if we do this, will it not be easier for us to make such a reply or take such action as will be most likely to bring them to Christ Jesus? for is it not true that our greatest work here on earth—the most important work that any of us have to do—is to get our friends and neighbors out from under the dominion and control of the evil one, and to bring them, by gentle words and mild measures, under the power of Christ Jesus, "the Lamb of God that taketh away the sin of the world?"

There is one special line of sin in which Satan is constantly at work. We seldom hear much of it, however, until it bursts on us and startles community with the suddenness of a thunderclap or an earthquake; and yet the steps that Satan takes to bring these victims to ruin and despair are very simple, and of such a nature that one might almost be excused for not thinking or even suspecting that a cloven hoof was anywhere concealed. It is a matter about which we seldom hear much said, or of which much gets into print, unless it is among the sensational news of the newspapers. It has often been said, that we, as a body of bee-keepers, are especially upright and moral in character and standing. While this is true, I feel that it were well that a danger-signal were raised aloft now and then, especially since, within a short time, two prominent brothers have fallen. When the papers came out with the sad story of friend Betsinger, I thought best to have as little said about the matter as possible. But our silence in the matter has troubled me some ever since. It troubled me because he was a prominent official in one of our universally recognized orthodox churches. In fact, his awful crime became possible because he was a *deacon* in the church. Now, by keeping silence we give scoffers good grounds for saying *because* he was a member of the church it was hushed up. I do not believe that any thing should ever be hushed up—that is, any thing in this line—because the guilty person is a church-member. On the contrary, church-members should be made to feel and to pay the awful penalty and consequence of taking such a fearful step across the wide gulf between Christ Jesus and the evil one. If anybody thinks that, because he is a church-member, or even a member of parliament, he can overstep God's holy command, the sooner he discovers his mistake the better; and I rejoice that the world at large decided quickly on the proper thing to do in the case of Parnell. Our friend Betsinger went to an orphan-asylum, and became constituted guardian of a poor homeless, friendless, and defenseless child, because he *was* a deacon in the church; and the first offense was long kept from an unsuspecting public, simply because he was a professor of religion, and he was allowed to go on and *repeat* a thing that fairly makes one shiver to think of. No, all this, friends, was simply the work of the adversary. Satan, little by little, got hold of him. Perhaps he may have struggled, and I think there is no question but that he did, for months and may be years, as the poor fly fights and struggles in the spider's web. Probably no human being knew of those struggles. I have told you before, that I think it is exceedingly bad for us to try to fight evil *alone*. Go to your wife; go to your pastor; go to your best friend, and tell him that Satan is striving hard for your soul. Ask them to pray for you or with you, and just see how the scales will fall from your eyes. When an intemperate man can confide his struggles to some good Christian friend, he is, for the time being, freed from the toils of the spoiler.

The second sad case is of recent occurrence. The following from the Boston *Herald* tells the sad story from Lewiston, Me., dated Dec. 30:

> The neighboring village of Mechanic Falls is excited over an alleged elopement. For years a neat sign bearing the inscription, "Home of the Honey Bee," has pointed out the entrance to a cozy cottage, which has of late been transformed into somewhat of a hornet's nest. It is the home of J. B. Mason, editor of the *Bee-Keepers' Advance*, the only paper in Maine devoted exclusively to apiarian interests.
>
> Mr. Mason is 53 years of age, and has been prominently connected with the Second Advent Church since his youth. He has four sons, two of whom are ship carpenters in South Boston, and two small boys at home; also a daughter, Mrs. Lizzie Bray, a widow who is stopping at home on a visit from Boston. Mrs. Mason is a genial woman, and their home has been a pleasant one, at least until within six months ago. Then it was that Charles H. Cotton, wife, and two small children went to board with the Mason family. From that time Mr. Cotton alleges his wife and Mr. Mason were too intimate.
>
> About five weeks ago Mr. Mason and his wife went to Boston to visit their sons, and Cotton claims that his wife received a letter from Mason, asking her to meet him at the Boston & Maine depot in Boston. On the afternoon of Dec. 22 Mrs. Cotton took her little girl and started for South Paris, telling her husband she was going to visit her sister. Mr. Cotton, being suspicious, harnessed up his team and followed her, only to learn that she had started toward Boston on the express train.
>
> The next afternoon, he says, Mason left Boston, and has been heard from since only by a letter postmarked White River Junction, Vt., addressed to Mrs. Mason in Boston, in which he said she might have his bee business, but that he would never return until he could pay his debts. Mrs. Mason is now in Boston.

The *Bee-Keepers' Advance* has already absorbed five other bee-papers, the last one being the *Bee-Keepers' Magazine*, which was long published in New York. Notwithstanding these consolidations, the paper does not seem to have prospered very well. We have been in frequent communication with friend Mason, and have felt more or less acquainted. He, too, was a church-member, and had been from his youth. However, this does not necessarily reflect on our churches, even though the world may think it does, more or less. It indicates this: That a man may be a member of a church, and at the same time not be a Christian. He may be a professor, but not a possessor. The promise is, "He that *endureth* to the *end* shall be saved. In our last issue we spoke about the celestial crown that stands just over our heads, as a promised reward to those who fight the good fight and overcome all of Satan's allurements. When our poor friend decided to let go of his religion, and to bid adieu to his Savior, to desert his wife and children, to give up his standing among men, his all and every thing, he deliberately agreed to forfeit all prospect of gaining that immortal crown. There is an old hymn that reads,

Jesus, I my cross have taken,
All to leave and follow thee.

This tells us what a Christian must do to follow Christ. *All the world* and all it has to offer must be dropped and given up for Christ. The thought has been an inspiring one to many a poor soul, since old Dr. Watts gave us the hymn. It rings out like the fife and drum to the fainting soldier.

Now, just for a minute take a glimpse of the awful contrast between one who leaves all for *Christ* and one who gives up all, as did friend Mason, for——what? Yes, let us pause a minute. What did the adversary hold out to our poor misguided, infatuated, and crazy brother, to induce him to leave friends and home, and all thoughts of eternal life? He probably deliberated long and earnestly in regard to his bee-friends and his bee-journal. Perhaps he said within himself, more than once, "O my God! I can't do it! I *can't* do it! I CAN'T do it!" Perhaps he added my own little prayer, "Lord, help! Lord, help!" Some of you may ask why the Lord did not help. Alas, my friend, God has made us free agents. While life lasts we have the power of choosing. In talking a few days ago with a prominent minister, a man of large experience, we were lead to speak of a case something like the above; and he added, "Perhaps the poor man was suddenly overcome by such terrible temptation that he could not help himself."

I stopped and raised my hands in horror.

"Why, Bro. P., you are surely jesting. No man was ever yet, since the days of Adam, overtaken by a temptation that he *could not* resist. In fact, we have Bible statements to the contrary. See what Paul says:"

> There hath no temptation taken you but such as is common to man; but God is faithful, who will not suffer you to be tempted above that ye are able; but will with the temptation also make a way to escape, that ye may be able to bear it.—I. COR. 10: 13.

It is possible, perhaps, that one who has given way to Satan (as an intemperate man does) again and again, may find his will power so impaired that he can not of himself resist any more. The trouble is, in this case, away back. One who prays for help, and then does not *help himself*, must expect to be lost.

It is possible that these words I am dictating may meet the eye of friend Mason, somewhere in the wide world. As the matter now stands, what is to be done? Can any thing be done? O ye of little faith, who ask such a question! While there is life something can *always* be done. What shall he do? Why, go back home and take that guilty companion back home. Undo all the evil, so far as human power can undo it, then commence a pure, honest, upright life at the foot of the cross. Satan's greatest hold is in making his victims believe there is neither help nor remedy. Just as soon as he gets one a little way into the meshes of sin, he commences making great capital of the point that there is no turning back. A boy in his teens is now in our county jail, with the penitentiary before him. He went with a lot of other boys to a neighboring town, and bought a bottle of whisky. Under the influence of the stimulant he stole his employer's horse. Before he had got away many miles, however, the effects of the liquor wore off, and he began to suffer the terrible pangs of conscience and remorse. It would have been a very simple matter to go back and confess the whole thing to his employer. Satan persuaded him that he would surely be arrested if he did. So he turned the horse loose, and went to his home, quite a few miles away, and for three or four days he suffered as no one can suffer who has not been through the same trial. Common sense should have told him that he would certainly be arrested, unless he went to his employer and confessed at the very earliest moment. But he was crazy and foolish. So is every one foolish and crazy who gets into the toils of Satan. Almost every one who commits crime loses his good common sense, and insists that he can not stay at home and live it down. Although it is the blackest lie that Satan ever got up, poor humanity insists on listening to Satan and not to good common sense. Perhaps friend Mason would not be *allowed* to set foot again in his own home. Well, even if this be true he should make the attempt, and do the best he can to undo the mischief. It takes only a *little* while, comparatively, for the worst criminal to regain the confidence of the friends he has lost, and to regain the confidence of the whole world. I have sometimes thought that mankind are only *too* ready to forget and to forgive, and to take back every truly penitent sinner. The first requisite, however, to being thus taken back, is to own up and confess. An attempt to evade or slip out, or to make believe that the thing is not so very bad after all, does not answer. A discriminating public detects the difference between *true* penitence and make believe, with a keen and unerring judgment.

I well know, however, how *loth* those who have fallen into crime are to *believe* what I say. May God in his infinite mercy and goodness bear me out in it. May the Holy Spirit *attest* the truthfulness of what I say. There are no exceptions; there are no possible conditions that should prevent the prodigal from going back at once. Christ Jesus himself, the Lamb of God that taketh away the sin of the world, has left a standing invitation, and the promise of pardon. He says, "Come unto me, all ye that are bowed down by the burden of sin and crime. Come unto *me*, and I will give you rest. My yoke is easy, and my burden is light." Oh that the penitent sinner could know *how* light and *how* easy, compared to carrying through life those burdens that are not only a *sin* against *God* but a *crime* against *humanity!*

SPECIAL DEPARTMENT FOR A. I. ROOT, AND HIS FRIENDS WHO LOVE TO RAISE CROPS.

GARDENING FOR FEBRUARY.

I presume that many of our readers think there is not much to be done in the month of February; but where the heart is full of love for working in the soil, I tell you there can be found plenty to do. In the first place, you can do underdraining; and it is not often that the market-gardener has nothing to do in that line. Just across the street from where I am writing is an acre of ground newly purchased. It was bought with the view of putting on buildings, and for use as a lumber-yard; but the boys say they are not ready to use it yet, and may not for a year or more; therefore I am going to make garden on it—yes, even though the land cost me more than $3000 an acre. Of course, some may say, "Why, can you make it pay to garden in land that cost so much as that?" My reply is, "How can we afford to let ground *lie idle* that cost so much as that?" Peter Henderson tells us of gardening close to the city of New York, where they pay more than this amount *every year* for *rent*. This is close to the highway, right where there is a large amount of traffic. Some beautiful beds of cabbage, tomato, and celery plants, right where crowds of people are obliged to see them, will make a better advertisement of our plants and garden-stuff than the most expensive sign—yes, or advertisement in the papers. My friend, if you wish to sell garden-stuff, remember there is no sign or advertisement equal to the stuff itself. If you put it in front of the groceries, without care, it will be wilted in a few hours; but in neat beds, growing right by the highway, especially if you have water in abundance, as we have, you can make an advertisement that will not only be a thing of beauty and a joy for ever, but it will pay you in dollars and cents.

Well, the first thing to be done is to underdrain this piece of ground. We are putting the drains 30 inches deep, and only 20 feet apart. They are to run up and down the slope the steepest way. All the books and agricultural papers teach that the quickest way to get water off from ground is to take it straight down hill; and I guess they are right, although I have felt like objecting a good deal. I am willing that the underdrains shall go straight down hill, but the surface drains must go diagonally to the slope. The *Rural New-Yorker* recently had a series of articles, in regard to which way the furrows should run on a sidehill. I was deeply interested in those letters; and I believe the general decision was, that straight up and down the hill is not the best way for the furrows, neither is it best to have them at right angles across the slope. The furrows should have fall enough to carry off the water when there is a great excess of rain, and no more. They ought to run so as to carry the water with a very slow current off the land, when it is fully saturated. At the same time, there should be no hollows where water will stand, even for a few hours, in a low place in the furrows. If it is left this way during a very heavy rainstorm, it will be likely to break through and cut gullies across the furrows. Underdrains running at right angles, or nearly at right angles to the furrows, would be likely to take the water off unless the amount of rain were very great. I think we may learn a lesson in this matter from our friends in the far West, in the way they work for irrigation. When in California I set out a thousand strawberry-plants for my brother. I was going to set the rows up and down the slope.

"Oh, no, Ame!" said my brother Jess; "that won't do at all. The ground lies too steep. The water will run right straight down the hill, and not wet the roots of the plants at all."

As the soil was a good deal sandy and quite porous, I was inclined to think that I knew better than he did; and you ought to have seen the laugh they had at my expense, to think that a "tender-foot," who hadn't been in California two weeks, should attempt to teach them any thing about irrigation. Now, their strawberry-beds, gardens, and every thing else, are so laid out that the water has just enough fall to run slowly. If the fall is not enough, it would soak into the ground before coming to the end of the furrow; if too great, the water would run off the ground and get away without soaking down to the roots of the plants. The golden mean of fall must be arranged according to the porosity of the soil. Well, in fixing our grounds so as to avoid the disastrous effect of drenching rains, we want to have our furrows run on just the same kind of plan we have them run for irrigation. Last season we had our furrows up by the windmill run straight up and down the hill. During a very heavy rain I watched how it worked. The ground had just been cultivated and worked up fine, and the rain was needed. For an hour or two it seemed to work just right; and while the water was coming down the sides of the road like a small millrace, every particle disappeared in the *freshly worked soil*, to my great satisfaction. Finally, however, the shower closed with a tremendous dash. The underdrains and the soft loose ground took it all for a while, but finally every thing was saturated and soaked, and the water commenced going down the furrows where there was a hollow. In fifteen minutes more, dark inky streams were coming down almost every furrow, showing that the strength of the manure that had been put on so lavishly was going down to the roadside, and mingling with the torrent which was fast hastening on to Champion Brook. Not only did the dark water go down to the roadside, but several loads of my finest and richest composted soil were piled up in the ditch; so you can understand why I do not want my furrows to run straight down hill any more. With the furrows arranged so as to cross the underdrains at nearly right angles, with just a gentle slope, I believe I can avoid wash and losing the strength of my manure, unless the rain should be so excessive that the manure-water should come out at the mouth of the underdrains. Where these drains are not less than 30 inches deep, however, and a deep loose soil over them, I do not believe that the water that comes out will be colored by the manure. I am going to watch carefully, however, and see.

REDUCING THE NUMBER OF VARIETIES OF GARDEN SEEDS, ETC.

Friend Root:—In GLEANINGS for Jan. 15, a person whose name is not given, but who, for convenience' sake, I will call "Seedsman," gives the other side of the question of reducing the number of vegetables in a seed list. I can agree with him in nearly all he says; but I think that he has made a mistake as to the effect of cutting down the list or varieties in a seed catalogue. While he does not say so in so many words, yet it is plain to be seen that he thinks the object in the seedsman in not reducing the number of kinds of seeds in the list is because it will reduce his sales—that is, the object of the seedsman in cataloguing a large number of varieties is to sell the greatest amount of seed and thereby put the greatest amount of money in his own pocket. I do not think that Seedsman will dispute me in this point; and if he did, a glance at the seed catalogues would convince one of the fact. Take the point of locality, which Seedsman makes a good point, and look in the catalogues and see whether you can find it mentioned; and yet he says that "seedsmen are constantly receiving reports from different parts of the country, that certain varieties do well there." But, now, Seedsman, if you'll look at GLEANINGS for Aug. 15, 1890, you will see that A. I. Root as a *buyer* and *user* of seeds sees the profit and pleasure, the economy and satisfaction, of planting and selling fewer varieties of vegetables; and then, as a seller of seed, he is trying to have his customers do the same thing, not to increase his sales of seeds, but for the benefit of the customer. This, perhaps, may seem to some a rather unbusinesslike way of doing things; but if more business were done on this plan, the world would be better; and it may, and I sincerely hope will, largely increase the sales of seeds by Mr. Root.

I can see many reasons why a catalogue can not be cut down to the extent that has been suggested, especially for the good of the seller; but for the buyer, the reduction would be a great saving.

Now, the objection that Seedsman makes to my saying that "the new kinds and sorts are mostly made by the seedsmen in order to have a novelty to introduce." I will say that I said what I meant in that, and still hold to it, and hope that during the coming season I shall have proof of my assertion, for the garden department of the Experiment Station will make special tests of varieties, and perhaps issue a bulletin on them.

But to think that Seedsman thinks that, for a seedsman to send out a novelty that was an old thing, would hurt his reputation, makes me laugh. Why, bless your soul, that is the very way *some* of them take to make a reputation, taking for their motto the oft-repeated saying of Barnum, that "Americans like to be humbugged." If all of the seedsmen who have sent out a novelty that was *not* a novelty should have their reputation blasted, we should have a sorry set of seedsellers. And it sometimes happens that the introduction of an old thing for a novelty is not a bad thing, for some of our older varieties are overlooked, and are good things in their place; as, for instance, Henderson's bush lima bean, or Maule's Prizetaker onion. E. C. GREEN.

Columbus, O.

[Friend G., the point you make, about seedsmen not saying in their catalogues what things are suitable for certain localities, is one that ought to be emphasized. We are continually testing things that may do somewhere, but they will not for us—John Lewis Childs' Pepino, or Melon pear, for instance. Thepicture and description are exceedingly taking, especially when he says it is as easily grown as a tomato. When he first announced it I sent 50 cents at once for a plant. I gave it the very best cultivation I knew how, but never got even a blossom. The next year I tried again; and as I got a larger plant I succeeded in getting blossoms, but not a sign of fruit. And now somebody tells us that they do not bear fruit *anywhere*, except in *Florida* or some tropical climate. Notwithstanding this, the advertisement in the catalogue reads just as it has for the past three years—"As easily grown as a tomato." Last season we had a watermelon that really "astonished the natives." It was so large I could hardly carry it, and it readily found a purchaser at a good figure. When he came to cut it, however, it was so green that it hardly had *seeds* inside, and yet it was growing the whole season, and we covered it with a carpet until after one or two frosts. It was a California watermelon, and not adapted to our season and climate. I wonder how many others have paid out money for the Melon pear. Now, in regard to bringing out old and well-known varieties under a new name: Among the catalogues before us I find *seven* different names for the Shoepeg corn, and two or three different catalogues picture it and describe it as a wonderful "novelty." If the Experiment Stations will tell us just how many of the things advertised in our seed catalogues are *real* novelties, and what are old things under new names, they will save our people who love gardening, thousands of dollars. Just another point: Some new thing is so near like something well known, that nine out of ten people pronounce it exactly the same thing. Where something is brought out with a difference so very trifling from some old well-known vegetable or fruit, is it right to coax people to buy it without telling them that it is almost like the well-known so and so? The Ontario strawberry was advertised and scattered far and wide until the universal decision was that it was just our old well-known *Sharpless* under a *new name*. Our real honest and upright seedsmen not only have no objection to allowing the Experiment Stations to do this work, but many of them furnish the seeds gladly, and free of charge, and offer them to the public only after the Experiment Stations have given them their recommend. May the Lord be praised for our Experiment Stations, and for the fearless, faithful, hard-working young men who have these matters in charge.]

EDITORIAL.

I will arise and go to my father, and will say unto him, Father, I have sinned against heaven and before thee.—LUKE 15:18.

RENEWALS are coming in fast. Thanks.

EIGHT VS. TEN FRAME HIVES.

IN the Question-box of the *American Bee Journal*, page 72, the respondents vote strongly for eight-frame hives, although a few favor the ten-frame.

SUBSCRIPTION RECEIPTS.

WE never send a receipt for money received for renewals. After you send the money, watch the little label on the wrapper of your journal; and if the date has been changed a year ahead, that means that your dollar has been received. At this time of the year, however, it sometimes takes a month or more before the dates on the labels are changed.

HOPEFUL.

OUR subscription clerk informs us that several who have written, requesting GLEANINGS to stop, have repented of doing so, and asked to have it kept going again. In fact, I have noticed quite a few such letters myself. You see, there is a delicate compliment. They began to feel lonesome, even at the *prospect* of bidding adieu to an old friend. Thank you.

PREMIUMS FOR NEW SUBSCRIBERS.

ANY subscriber who will take the pains to secure a *new* name besides his own for GLEANINGS may retain 25 cents and send us 75, providing he agrees not to take any subscriptions for less than the advertised price, $1.00. If he obtains more than one name besides his own, a part may be renewals and part new names; but at least half of the names must be new.

LOOK OUT FOR THEM.

OUR friends Miller Bros., of Bluffton, Mo., wish us to caution bee-keepers in regard to the Indiana Paint and Roofing Co. We have written the above firm at two different times; and although they replied, they certainly do not seem disposed to make good their warrant on their roofing. And, by the way, is there any sort of roofing that is really reliable, and worthy of notice, unless they use shingles, slate, tin, or iron? I have seen so much dissatisfaction from all kinds of cement, paint, and paper roofing, that I confess I am a good deal incredulous.

DEATH OF MR. ALFRED NEIGHBOUR.

WE learn from the *British Bee Journal*, that Mr. Alfred Neighbour, of London, England, died on the 19th of last December, after an illness of considerable duration. Mr. Neighbour was a prominent bee-keeper in England, and the oldest of the appliance-makers. He wrote a bee-book, entitled *The Apiary*. It passed through several editions. The *B. B. J.* says, "He was extremely affable, and always ready to assist one in bee-keeping. His strict integrity caused him to be trusted by all who knew him."

THE DOVETAILING IN HIVES IN DEMAND.

WE have just received a letter from a correspondent in Utah, Mr. Willard Bishop, of Kaysville, Davis Co., to the effect that a dovetailed corner on hives will be a great advantage in their climate. He says that ordinary nailed joints are not strong enough to stand their climate; that the nails of an ordinary lap joint do draw because of the drying out and warping of the boards in the sun. The dovetailed joint is not only cheaper, but there is a demand for it in several of the Western States, where the climate is such as to make the ordinary box joint insufficient.

HONEY FROM THE SANDWICH ISLANDS.

ONE of our old acquaintances, Mr. Chauncey N. Pond, of Oberlin, O., has just returned from a visit to the Sandwich Islands, and has left with us a sample of honey from that part of the world. We expected to find something dark-colored and poor in flavor, as the honey from the islands of the sea usually is. We were agreeably surprised to find, however, that it is not only of a beautiful color but of exquisite flavor. It reminds us very strongly of alfalfa, which is so popular at our house. We should be very much pleased to have one of our subscribers in the Sandwich Islands tell us more about it, and of the progress of apiculture as it is on those islands.

HOW TO WINTER BEES.

ON page 36 of our catalogue, for the benefit of beginners and others we have given the very latest there is in regard to wintering, in doors and out; how to pack in chaff on summer stands; how to carry bees into the cellar, and how to stack them up there. In fact, they are the same instructions as are given in the A B C book, boiled down. We have also given instructions on how to feed and how to do a great many other things. Our new catalogue is not only a price list and description of implements, but it contains a good deal of instruction for the benefit of bee-keepers. It will be cheerfully sent on application.

THE NUMBER OF QUEENS WE IMPORT FROM ITALY.

I SEE it is reported in one of the bee-journals that we import annually about 200 queens from Italy. If this figure were split in two it would be more nearly correct. We do not know how the mistake occurred, but perhaps through our fault in some way. In 1885 we imported 130; and during successive years our importations went down to nearly nothing while we had foul brood. In 1889 we imported 50; in 1890, 98. The fact is, one imported queen can be the mother of hundreds of daughters; and as they will live on an average about three years it does not take many queens to supply the prominent breeders, to say nothing of the importations that are made by other parties.

WHAT A VISITOR SAYS OF THE HOME OF THE HONEY-BEES.

WE have just had a very pleasant call from a couple of bee-keepers, one of them an Iowa man and the other a native of our own State. Said Mr. Firman, the gentleman from Iowa, after we had shown him about our premises, "Why, I had no idea you had such an *immense* plant. We get glimpses, occasionally, of some of the improvements in GLEANINGS, but there are few subscribers who realize the number and size of your buildings." This remark has been uttered so many times by visitors that we thought possibly some of our customers and other subscribers might like to get this bit of news. Our plant has been very much enlarged of late, and we are always glad to welcome our bee-friends; and while we can not always take the time to show them around, we want them to feel perfectly at home, and free to go through all the departments, and ask all the questions they wish. Our establishment is open from half-past six in the morning till seven at night, every day in the week except Sunday, and some times it is open and running night and day.

Our list of subscribers now numbers 10,054.

NEW YORK STATE BEE-KEEPERS' ASSOCIATION.

E. R. has just returned from a meeting of the said association, in Albany. We will try to give a report of it in our next issue. Although an off year, there was a good attendance, and the discussions were practical and to the point.

BEE-KEEPING IN DIXIE.

We have just printed a 60-page catalogue, with tinted cover, for Jenkins & Parker (formerly J. M. Jenkins), Wetumpka, Ala. This is not only a catalogue of implements, but it is quite a little text-book besides. Over half of it is descriptive, and is especially designed for the instruction of the Southern bee-keeper. Apply to the address as above.

THE OHIO STATE BEE-KEEPERS' ASSOCIATION.

Remember the time and place of the meeting of the association above—Feb. 10, 11, Toledo, at the Merchants' Hotel. It is expected that quite a number of Michigan bee-keepers will be present, and, altogether, we shall probably have one of the most profitable meetings ever held in the history of the association. The program is given elsewhere. Dr. A. B. Mason will be the presiding officer, and that bespeaks a good time, and lots of fun and profit for all who attend.

ADVERTISEMENTS THAT SAVOR OF LOTTERY SCHEMES.

We can not accept any advertisement that gives one purchaser any advantage over another by any scheme of luck or chance. Of course, this would not include special prices to those who made their orders early before the rush of business. But we must refuse to accept any thing that even indirectly encourages a taste for getting money by chance or luck. This sort of craze gets hold of people fast enough without any encouragement on the part of respectable journals and periodicals.

TEMPERATURE FOR CELLARS.

The temperature for our bee-cellar this winter has been in the neighborhood of 40. Last year it was from 45 to 50. The bees are in very much better condition than they were a year ago. Prof. Cook said, at the late Detroit convention, that he now prefers from 38 to 40. E. R. believes he is right. The old standard has has been all along about 45. Is it not possible that we have been mistaken? Last winter I noticed that, when the cellar went down to 40, the bees were quieter. Because the books said 45, I made efforts to raise it to that point, and keep it so, as nearly as I could. Last year at this time there was about an inch of dead bees on the floor; but now there are not more than 200 or 300. After all, are bees doing well in the cellar when there is an inch or so dead ones on the floor?

GIVE YOUR POSTOFFICE.

When you are renewing, be sure to sign your name and give your *postoffice* address. Every year, about this time, we receive a lot of renewals, with the mere signature, and nothing else. Most of them, with a great deal of trouble, we can hunt out on our books, and the rest have to lie until the subscriber "growls." Sometimes a subscriber will write from a postoffice other than the one to which his journal is sent. Another big hunt has to be started to find out where his journal goes. If our friends would be a little more careful it would save us a great deal of work. We have scolded about this so much that it sounds like a mere repetition; but it is one of the things that publishers are obliged to harp about more or less all the time. Remember, our subscription list is indexed according to *postoffices*, and not according to *names*.

REDUCED RATES TO THE OHIO STATE BEE-KEEPERS' CONVENTION.

The following, from Dr. A. B. Mason, will be of interest to Ohio, Indiana, and Michigan bee-keepers:

> *Friend Root:*—Please say in next Gleanings that a 1⅓ rate of fare has been secured for the round trip on railroads in Ohio and Indiana, to attend the Ohio State Bee-keepers' convention, to be held in Toledo, at the Merchants' Hotel, on the 10th and 11th of Feb. Rates at good hotels vary from one dollar up. In order to secure reduced rates of fare, let all buy certificates of their railroad agent, to attend the Ohio Republican League convention and banquet, and I will fix them so they will be good for one-third return fare. Tickets can be bought on the 10th, 11th, and 12th, and will be good for return up to and including the 14th. For parties coming from Michigan, the rate is two cents a mile each way, when parties of ten or more come and return together on one ticket, which must be bought as above for the Republican League convention and banquet. Write me for any further information that may be desired.
>
> Auburndale, O., Jan. 22. A. B. Mason.

LIFE-MEMBERSHIP IN THE N. A. B. K. A.

Since our last mention of the number of names that were already enrolled as life-members only one has been added. What's the matter? To make the association a power for good we need many more substantial life-members. One of our correspondents writes, that, if we "will merge the Bee-keepers' Union into the N. A. B. K. A., here is $10.00 for life-membership." We have scarcely given this matter a thought as yet, and consequently are unable to express any opinion as to the wisdom of such a course. We rather prefer to see what the General Manager thinks. If he and the other officers approve, it might be advisable to consider it in convention at the next session of the N. A. B. K. A. in Albany, but Manager Newman should still be at the head of the present Union. The following is the list of life-members:

D. A. Jones, Beeton, Ont.
Thomas G. Newman, Chicago, Ill.
A. I. Root, Medina, O.
E. R. Root, Medina. O.
J. T. Calvert, Medina, O.
Charles Dadant, Hamilton, Ill.
C. P. Dadant, Hamilton, Ill.
Eugene Secor, Forest City, Ia.
Dr. C. C. Miller, Marengo, Ill.
O. R. Coe, Windham, N. Y.
C. F. Muth, Cincinnati, Ohio.

HOW TO GET GLEANINGS FOR LESS THAN A DOLLAR A YEAR.

A large part of our subscribers are those who have been with us for years, and who, no doubt, expect to continue with us for years to come. To favor these and others who will liberally patronize us we have decided to make them this offer: We will send Gleanings for one year for $1.00; two years for $1.80; three years for $2.50; five years for $3.75; but to do this we must have cash in *advance*. If you have been so far pleased with it and the improvements it has inaugurated from time to time, you will probably wish to remain a subscriber; and the best thing for you to do, if you want to save money and do away with the bother and machinery of renewing annually, is to send $3.75 and we will make you a subscriber for *five years*. If your address is right, the journal will go to you uninterruptedly for that length of time. We propose to make this a standing offer. Any subscriber, new or old, can take advantage of it. Now, perchance you have just sent in your dollar for renewal, and you wish to take advantage of this offer. If you will send the balance *at once*, say $2.75, we will send it four years longer; or $1.50 two years longer; or 80 cts. one year longer.

RECESS AT BEE-CONVENTIONS.

WE attend conventions to hear the essays and subsequent discussions, it is said; but after a session has been held for a couple of hours, it is a great rest and pleasure to have the president announce a short recess. How pleasant it is to feel the warm grip of one whom we have long known through the printed page, and whom, for the first time, we now meet face to face! No, we do not attend conventions simply to hear the essays and discussions. We go to see, hear, and feel the personality of the good brothers and sisters who attend. Some of the most valuable ideas gleaned, oftentimes, are in the between sessions; and our presiding officers should give ample opportunity for hand-shaking, and this dual exchange of ideas.

A VISIT TO THE HOME OF THE HONEY-BEES, FROM DR. G. L. TINKER.

WE had a very pleasant call last week from our genial friend Dr. G. L. Tinker, of New Philadelphia, O. Many of our readers will remember him as the very fine workman who makes such perfect queen-excluding zinc, and such beautiful four-piece white-poplar sections. He was kind enough to give our saw-filer some hints in filing, to do smooth work rapidly—a secret he had heretofore kept to himself. He seemed to enjoy his visit very much, being agreeably surprised at the size and equipment of the Home of the Honey-bees, and many times complimented us on our work by the remark that it was much better than we used to do. He was on his way to Ashtabula to visit his brother and bring home a new zinc-perforating machine by which he would be able to make sheets of his zinc as large as 24 by 36 inches.

MORE UNCHARITABLENESS.

THIS time it comes from the Philadelphia *Cash Grocer*, of Jan. 12. This journal purports to be devoted to the best interests of retail merchants and country storekeepers; but I do not see how their best interests are subserved by statements like the following:

"The profit in teas is simply great. The tea sold by retail tea-dealers at 60 cents costs them 18 cents a pound; and other teas sold at 50 and 55 cents per pound cost 20 cents. There is big money in the tea business, if the trade can be had."

And here is another:

"The explanation of the great amount of maple syrup and honey in the market is found in the enormous product of the glucose factories, amounting to a million pounds per day. There are not trees and bees enough to produce the syrup and honey in the hands of the trade."

I wonder whether the *Grocer* folks judge other people by themselves when they say that the retail dealers charge 60 cents for what costs them only 18, and a staple article besides. They should be ashamed of themselves. In regard to honey and maple syrup, there may be some adulteration; but the statement that there are not trees and bees enough is not true. Perhaps it will astonish them somewhat to know that there are bee-keepers nowadays who raise honey by the carload; and I imagine that there are maple-trees enough too. If there is really any adulteration in syrup going on, as well as in honey, which is to some extent true, why not say so in moderate terms, and then let us all join and fight it, without flings like the above, against large classes of honest tradesmen?

HOW TO MAKE THE GARDEN PAY.

THIS is the title of a bright new book just published by Wm. Henry Maule, written by T. Greiner, author of the new onion-book, mentioned just below. This is certainly the ablest book, clear up to the present time, before the world. The description and comparison of the variety of methods of gardening under glass, commencing with cold-frames, then taking up cold-forcing-houses, next forcing-houses with steam-pipes or flues, and finally discussing the respective merits of steam and hot water, is worth to me a ten-dollar bill, to say nothing about the rest of the book. The engravings are beautiful; the print is second to none; and, best of all, the author is a practical gardener—one who loves the dirt, especially when it is enriched up to its highest capacity, and who evidently loves every tool used in the garden. He is not only conversant with all the new seeds, plants, and fertilizers, but he evidently has read up almost every thing written in the agricultural papers on the subject of market-gardening. The book is 6 inches wide, 10 inches long, ¾ inch thick, and contains 272 pages, and ever so many pictures. I have not had time to count them yet. If you have any notion of building a greenhouse, either for flowers or vegetables, or even if you want to make a hot-bed or cold-frame, it will pay you to have the book. We can furnish it postpaid for $2.00; or you can have it with GLEANINGS for $2.50 for the two.

THE NEW ONION CULTURE.

This is the title of another good book by our good friend T. Greiner, better known through the agricultural papers as "Joseph." It gives almost exactly the plan of raising onions described in our last issue. The book is finely illustrated, and is written in one of Joseph's happiest veins. In fact, the story is so taking that almost anybody might read it from beginning to end without a thought of being weary; and to one who loves gardening it is a gem among books. The only fault or criticism any one could make is, I think, that there is not enough of it, especially for the price, 50 cents. There are only 62 pages in the book; the type is large, and the work very open. The paper, however, is heavy and fine, and the print beautiful. If bound in cloth instead of paper covers, the price would not be an objection. The author admits that the price may seem high, but he thinks the discovery or secret really cheap at the price. This latter is true; but we should remember that the whole thing is given in our Ohio Experiment Station Bulletin for October, 1890. The Bulletin, however, does not go into the minutiæ in regard to every point of the work that the book does. We can furnish the book postpaid for 50 cents. If wanted by freight or express with other goods, 5 cents less. Or we will club it with GLEANINGS for $1.40. The Bulletin is furnished free of charge to all Ohio people; and I presume it will be furnished to those outside of this State for a very small sum. I think it will pay many times the cost for every one who sows a paper of onion seed, to use these helps. Joseph recommends that we start with an ounce of onion seed; and you *may* make enough on this single ounce to pay the cost of the book *fifty times over*. This seems like pretty strong language; but those who have tried starting large onions under glass will, I think, bear me out.

Illustrated HOME JOURNAL

3o Quarto pages—50 **cents** a year.

AN Elegant Monthly for the **FAMILY and FIRESIDE.** Printed in the highest style of the art, and embellished with magnificent Engravings. Sample FREE. Agents Wanted.

HONEY COLUMN.

CITY MARKETS.

KANSAS CITY.—*Honey.*—The demand for comb honey is more liberal. Receipts and supply are very light. We quote 1-lb. comb, white, 16@18; dark, 12@14; 2-lb. California, white, 14@15; same, dark, 12@13. Extracted, 6@7. *Beeswax*, 22@25.

CLEMONS, MASON & CO.,
Feb. 11. Kansas City, Mo.

ST. LOUIS.—*Honey.*—No extracted honey in market. It would bring, if bright, 6½@7c. Comb in light demand at 13 for dark, 16@17 for bright. *Beeswax*, prime, 26@27c. D. G. TUTT GRO. CO.,
Feb. 11. St. Louis, Mo.

CINCINNATI.—*Honey*.—Demand is good for extracted, with a liberal supply on the market of all but Southern honey, which is still scarce. It brings 6@8 cts. a lb. on arrival There is a fair demand for choice comb honey at 16@17c a lb. in the jobbing way. No sale at all for dark comb honey. *Beeswax* is in good demand at 24@26c a lb. for good to choice yellow on arrival. CHAS. F. MUTH & SON,
Feb. 14. Cincinnati, O.

CHICAGO.—*Honey.*—Market continues to be weak in tone, only small lots being taken by the trade, and that which falls below a choice article is very slow of sale. Best grades bring 17@18c; fair, 15@16c; dark, 12@13c. Extracted, steady at 7@8c, and in fair demand. *Beeswax* is selling at 28c for yellow to mixed.

R. A. BURNETT, 161 S. Water St.,
Feb. 10. Chicago, Ill.

ALBANY.—*Honey.*—The demand for comb honey is good for this season of the year, and stock on the market is small. Extracted buckwheat in good demand. No change in prices.

CHAS. MCCULLOCH & CO.,
Feb. 11. Albany, N. Y.

NEW YORK.—*Honey.*—Extracted dark in good demand at 7@7½c per lb. California light amber, 7¼; white, 7½. Comb honey all sold. *Beeswax*, 29c; supply small. F. G. STROHMEYER & CO.,
Feb. 11. New York City.

BOSTON.—*Honey.*—Fair demand for honey; supply very short. Fancy 1-lb. combs, 19@20c; fair to good, 18@19c; 2-lb. combs, 16@17c. Extracted, 8@9c. No *beeswax* on hand. BLAKE & RIPLEY,
Feb. 11. Boston, Mas.

SAN FRANCISCO.—*Honey* remains firm and in good demand, and we quote: Extracted, 5½@6½; comb, 12@15. *Beeswax*, 25c, and in good demand.

SCHACHT, LEMCKE & STEINER,
Jan. 22. San Francisco, Cal.

DETROIT.—*Honey.*—Comb honey is selling slowly at 14@15c per lb. Extracted, 7@8c. *Beeswax*, 27@28c.
Bell Branch, Mich., Feb. 11. M. H. HUNT.

FOR SALE.—Choice white-clover extracted honey, in 120-lb. cases; per case, $12.00. Autumn honey, per case, $9.00. J. A. GREEN, Dayton, Ill.

FOR SALE.—700 lbs. of clover honey in home-made kegs holding 55 lbs., for 8½ cts., delivered on cars at Farley. Can ship by I. C. R. R., or Chicago, St. Paul & Kansas City, or the M. & S. P. R. R.
4d JAS. SCOTT, Farley, Ia.

FOR SALE.—Six 60-lb. 5-gallon tin cans of clover extracted honey, at $5 per can. F. O. B. cars at Otsego. CALVIN LOVETT, Otsego, Allegan Co., Mich.

FOR SALE.—2000 lbs. comb honey in 12 and 24 lb. crates. L. WERNER, Edwardsville, Ill.

FOR SALE.—500 lbs. choice extracted honey, at 10c here, pkg. included. W. H. S. GROUT,
Kennedy, Chautauqua Co., N. Y.

FOR SALE.—Extracted honey, in 70-lb. tin cans, at 10 cts. per lb. f. o. b. LEWIS HAINES,
4d Moons, Fay. Co., O.

FOR SALE.—1200 lbs. extracted white-clover honey in barrels or 60-lb. cans, as desired.
1tfdb E. J. BAXTER, Nauvoo, Ill.

FOR SALE.—Choice honey in sections, cans, and C. pails. Send for price list to OLIVER FOSTER,
12-tfdb. Mt. Vernon, Ia.

PRICE LISTS RECEIVED.

Since our last issue we have received price lists of bees, hives, and apiarian supplies in general, from the following parties:

Leahy Manufacturing Co., Higginsville, Mo.
W. A. Chrysler, Chatham, Ont.
D. A. Jones Co., Beeton, Ont.
G. M. Doolittle, Borodino, N. Y.
A. A. Byard, West Chesterfield, N. H.
J. W. Rouse & Co., Mexico, Mo.
Luther & Horton, Redlands, Cal.
E. Kretchmer, Red Oak, Ia.
A. L. Kildow, Sheffield, Ill.
B. Davidson, Uxbridge, Ont.
Jacob T. Timpe, Grand Ledge, Mich.
W. J. Row, Greensburg, Pa. Queens only.
Burdsall Apiary & Supply Co., Lebanon, O.

The following are from our press:

J. D. Goodrich, East Hardwick, Vt.
Levering Bros., Wiota, Ia.
E. J. Shay, Thornton, W. Va.
J. F. Michael, German, O.
J. E. Stewart, Prophetstown, Ill.

THROUGH AN ERROR,

My advertisement in GLEANINGS, Feb. 1st, **inside back cover** (which please see), failed to say: For $2.00 I will send 1 lb. each of Timpe's Seedlings Nos. 1, 2, and 4, postpaid; or for $2.25 I will send 1 lb. each of Nos. 1 and 2, and 2 lbs. of No. 4, prepaid (give your express office). Remember, I am giving **one full colony** and **seventeen** 3-frame nuclei of my **five-banded Italians,** for largest yields, largest potato, and best names suggested. And to every order received within 30 days **from this ad't** I will give from **2** to **5 packets** of choice **garden-seeds** (novelties) **free.**

Order now, before the stock is exhausted. Potatoes and seeds will be sent the last of March or first part of April, **all charges paid.** If possible, send express or postoffice money order. Catalogue now ready, mailed for 1-cent stamp.

Jacob T. Timpe, Grand Ledge, Mich.

ROOT'S COMB-FOUNDATION MILLS.

We wish to say that we are handling Root mills this season, and can furnish them to the bee-keepers of Canada less than you can buy a single mill from Ohio. All mills warranted. Write us if you want to buy. You will save money by doing so. We shall sell comb foundation, brood, at 40 cts. per lb.; section comb at 45 cts. All wax will be bought from Eckermann & Will, Syracuse, N. Y., and every pound warranted pure wax, or $5.00 will be given for every pound that is not right. **R. E. Smith,**
Box 72. **Tilbury Center, Can.**

FOR SALE. The walls and water power of an abandoned gristmill, 10 acres land in a good location for a bee-supply business. No factory near, and large apiaries in every direction, or will take partner. Address GEO. W. RANDALL,
4-5d Big Rock, Iowa.

FOR SALE. Three or four S. C. B. Leghorn cockerels, as good stock as can be found in the world. Come and see them. Write for prices with your address on postal, and you will receive by return mail my new descriptive circular, free.
4-5-6d ROBT. C. SMITH, Swissvale, Pa.

WANTED FOR CASH. From 50 to 75 colonies of Italians or hybrid bees, to be delivered about first of May. Langstroth hives preferred.

GLEANINGS IN BEE CULTURE

A JOURNAL DEVOTED TO BEES AND HONEY AND HOME INTERESTS.

Published by A. I. Root, Medina, O.

Vol. XIX. FEB. 15, 1891. No. 4.

STRAY STRAWS

FROM DR. C. C. MILLER.

A State society is beginning to be talked of in Illinois.

Hutchinson calls me a "gossiper." Wait till I catch him away from home.

A trade-mark for a body of bee-keepers is talked of. It might be a good thing. It might be a bad thing. I don't know.

Drones, Prof. Cook thinks, depend on the nurse-bees for their albuminous food—an additional argument against tolerating them.

Illinois doesn't propose to be left in the rear. She has a bee-keeper in her legislature—J. M. Hambaugh, Spring, Ill., a good square man.

Fire in bee-cellars is needed if too cold. I use it oftener for ventilation. Heat the air, and the cold outside pure air will rush in to take its place.

Heddon says the black bee is most amiable of all, but stings more, because it takes wing more readily. I'd rather have bees that don't take wing so readily.

The editorial "we" has been banished from the columns of the *Review*, and Hutchinson slings around his I's as easily and gracefully as if he had *always* talked good English.

I swept out the shop cellar for the first time, Jan. 13. I got about two quarts dead bees—not many from 112 hives after 66 days' confinement; time enough for bushels, though, before spring.

Painted muslin is not advisable for hive-covers unless it is better than oil cloth. I tried 200 covers of extra good oil cloth, and they lasted so short a time that tin is much cheaper.

No fire in my bee-cellars this winter till Jan. 10. Then I saw some mold on dead bees on cellar bottom; didn't smell just the best. Temperature 42°; raised it to 53°. This was in shop cellar.

A small bee-space between top-bars and sections was considered, at the Northern Illinois convention, of as much or more consequence, in preventing brace-combs, as thick top-bars.

Poison for mice is thus daintily served up by E. C. Eaglesfield (*A. B. J.*). He says, "I take a cooky and moisten one side, then place the crystals of strychnine all over it, and lay it where nothing can get at it but rats and mice."

"Observer," in *C. B. J.*, wonders what I'll think when I hear that "steps are being taken to put a stop to the importation of bees by the pound from Uncle Sam's, unless they have passed through quarantine." I think that Canadians will show good sense to take any steps to make the danger from foul brood less. If I had smallpox at my house. I shouldn't want any of the family to go to a neighbor's.

Lamps and oil-stoves have been used to warm cellars, but I never tried any thing of the kind till this winter. Then I put a gasoline-stove in the shop-cellar. It's better than none, but I don't like it. The combustion fouls the air.

"Bees visit only one kind of flower on the same trip." That's old but not always true. When forage is plentiful it may be true; but when scarce they'll change from one kind to another several times on the same trip. I've seen 'em do it.

A honey house or shop, a number of writers in the *Review* agree, should be at the *side* of the apiary, never in the center. Heddon makes a good point in preferring it at the south side, that you needn't look against the sun in watching for swarms.

Taylor's secret is out. The *Review* says he keeps his honey in a warm honey-house, with fire in winter. Of course, it's a good plan. More than that, I suspect if the place is kept hot enough long enough in the fall it will do with little or no fire through the winter.

"Do bees eat eggs?" That's the question up now, and I hope we'll learn when they do and when they don't. I know I've had bees starve to death, leaving eggs in the hive; and I know if I remove a queen from a hive, I expect nearly all the eggs to disappear within 24 hours.

The Review is getting down to business, reviewing. Hutchinson knows how. Now that I've had my fling at him, I must own up that he has furnished plenty of material from which good cream could be had. He did a good job of skimming, too, on the new books that were published last year.

Another idol fallen. I've always had such faith in Prof. Cook, but I've found him out at last. Friend Root tells (p. 61) about a man being hasty, and imagining evil of others, and then says Prof. Cook has done much to bring about this state of affairs. And to think that I had loved the professor as a brother!

Manager Newman says: "Suppose now, that in America it were once established by law, that, to wantonly kill bees, were a punishable crime! How quickly the owners of the deadly cider-press and sugar-refineries would have to *screen out* the bees—or the Union would be after them!" Well, "suppose now" the Union gets such laws made.

Legislation is coming to the front as one of the needs of bee-keepers. Daniel Wyss, in *American Bee Journal*, calls for laws forbidding poisonous spraying when trees are in bloom. Different States are asking legislative aid to help the honey show at the World's Fair. Prof. Cook, in his president's address at the Michigan convention, urged a law against spraying fruit-trees in bloom. About three-fourths of the convention were with him. They appointed a permanent committee on legislation.

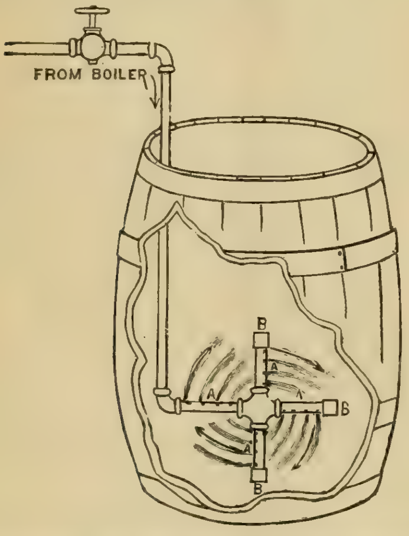
GENERAL CORRESPONDENCE.

RENDERING COMBS WITH SULPHURIC ACID.

HOW TO GET THE MOST WAX POSSIBLE OUT OF OLD COMB.

After reading E. France's article on rendering old combs into wax, on page 15, I thought I could give you a better plan, and one which would take that dark-colored wax and make it into as nice wax as any you ever saw. It will be so clear, that, when melted, you can see to the bottom of a dipperful, looking like wine. By this plan you can take the refuse of cakes of wax, that which is scraped off the bottom after cooling, and looks like sand, and make it into as nice wax as can be made. This last season we had a barrel of this dark stuff, which looked like dirt, and you would have said it was not worth the trouble; but I put it through the process, and got from it 60 lbs. of yellow wax, worth at least $15.



APPARATUS FOR RENDERING REFUSE WAX WITH SULPHURIC ACID.

I know that iron or galvanized iron will turn wax a dark color. I went to quite a little expense rigging up steam-pipes, and tanks of galvanized iron for my foundation business. The first melting did not show much, but after melting the scraps over three times I stopped making and tried to find out what was the matter. I knew the wax at first was all right, and concluded, after a while, it was either the galvanized iron or steam of too high pressure. I then went to work, tore down all the fixtures, and went back to melting in a large wooden tub. This wax, which was almost a dark green, I put through my process of melting, and had yellow wax again. My plan, whereby I can render 100 lbs. of wax from old combs in three hours, is as follows: Get a barrel that is good and strong, and ⅜ steam-pipe, long enough to reach from a steam-boiler to the bottom of the barrel. Copper pipe would be better, but I find the small surface of the pipe touching the wax does not make any appreciable difference. You want a valve to shut off the steam, four pieces of pipe five inches long, an elbow, a cross, and three caps. In the pieces of pipe five inches long drill three 1/16-inch holes, spaced about two inches apart; screw an elbow on the bottom of the pipe coming from the steam-boiler; then one of the short pieces of pipe in the elbow; now screw on the cross, then the three pieces of pipe, and put a cap on the end of each. Turn the pipes until the small holes point all one way, so the steam in issuing will set the water whirling. Now fill the barrel one-fourth full of clear water. Put in one pound of sulphuric acid; turn on the steam, and when boiling put in the old combs. Let all boil until heated thoroughly, and stir with a large stick at the same time.

Now you will want a press. Mine is simply a box made large enough to hold three racks, made of ⅜x½-inch square sticks 15 inches long, nailed to two end pieces 15 inches long, so there will be ⅛ inch between the slats. In the bottom of the box I have a tin dish one inch deep, and it just slips down inside nicely. At one side the tin is turned down, and a hole is made in the bottom of the box for the wax and water to run out. Get a rim two inches wide and twelve inches square made from ⅜-inch stuff, and three pieces of burlap three feet square. Lay one of the racks in the tin dish in the bottom of the box; on this the two-inch rim; over this one of the pieces of burlap. Press the burlaps down in the rim, and dip the melted wax over into it until full to the top of the rim. Bring the burlaps over the top; take out the rim; lay another rack on top of this, and so proceed until you have the three filled; then place a follower on top of all, and a common jack-screw on top of the follower. Make a frame out of 2x4 scantling to go under the box and come to the top of the jack-screw. You will want two bolts to go through the top and bottom pieces of the frame. Have them of ⅝ round iron, and screw the nuts up tight. Put the top piece of the frame over the jack-screw, and turn the screw slowly so as to give a chance for the wax to run out. After it has stopped running, take out the refuse, and you will find the wax nearly out. You could not get out of a barrel of comb, after pressing, if it were possible to get it out, over a teacupful of wax. We have tried a number of ways, but the above is the best.

I tried an arrangement inside of a barrel to continually stir the comb; and over the comb, under water six inches, I had a screen to keep refuse from rising. I thought all the wax would in time rise to the top, but more stayed under the screen than came to the top. I also tried keeping two barrels of comb, that was thoroughly broken up, moist with water for two years, to see if I could not rot the cocoons and pollen so it would be like dirt. If I could rot it, I could get out all the wax, and not make me a press, but simply melt it in water, and the dirt would settle. This was a failure. The smell of the stuff when melting would fairly knock a man down at ten rods. I was very sick with malaria shortly after. Some thought I caught it from that bad-smelling boiling mixture. The wax I did get out of it was all right. I had to use the press to finish up. No more jobs like that for me. I can take cakes of wax that come to me dark, and, after rendering, they will be a nice yellow color. You simply want to melt them in the acidulated water, cover the barrel over tight, and throw an old horse-blanket over the whole; let it stand five hours, and then dip out in pans carefully, so as not to disturb the dirt at the bottom. Save all the refuse from scraping the bottom of cakes, and put through the same process.

F. A. SALISBURY.

Syracuse, N. Y., Dec. 5, 1890.

[Thanks for your valuable article. When I visited the Dadants a few weeks ago I learned that they treated their refuse, that would not refine by ordinary methods, with sulphuric acid. I do not remember just exactly the proportion of sulphuric acid they use with the water, but I think their method and plan was very similar to the one you describe. If I am wrong they will please correct. Mr. Dadant told me when they first used sulphuric acid, the man who used it earned for them $75 the first day, and a smaller amount the second day, until all the cast-away wax refuse which could not be refined by ordinary methods was used up. The price at which wax now sells renders this a very important matter. Mr. C. P. Dadant told me not to throw away old refuse; that a great deal of first quality of wax can be gotten from it by the use of the solar wax-extractor and sulphuric acid. The action of the acid seems to be to rot or disintegrate the cocoons and other matter, so as to free the wax.] E. R.

MANUM'S VILLAGE APIARY.

HOW FRIEND MANUM MANAGES TO AVOID HAVING HIS BEES TROUBLE HIS NEIGHBORS.

Mr. Editor:—Having often been asked by bee-keepers and others whether my bees in the village were troublesome to my neighbors, I will give you a little of my experience in this respect, as related to my friend J. H. Larrabee, in answer to his questions while visiting me.

"Manum, do your neighbors ever complain that your bees are troublesome here in the village?" asked Mr. Larrabee.

"No, not very much. In fact, nearly all seem to be interested in the success of my business, and they show a very friendly disposition toward the bees. There are times, however, when I have to be on my guard to prevent any annoyance to my nearest neighbors. For instance, in the spring of the year, when the bees have their first flight, if it happens to be on a washing-day, the ladies in the vicinity of the apiary scold a little if their clothes get spotted, as they most certainly will if put out to dry when bees are flying; but many of them have learned to wait until the bees have had their flight, before putting out their clothes, especially those who have had their clothes soiled once to the extent that they were obliged to wash over again."

"Suppose they are thoughtless, and do put out their clothes, and they get spotted; how do you manage an amicable settlement?" asks Mr. L.

"Oh! that is quite a simple matter. Whenever I learn that my bees have soiled my neighbors' clothes, or annoyed them in any way, I just present them with a few boxes of honey, which has never as yet failed to sweeten and harmonize their natures."

"I notice one of your neighbors has a nice lot of fruit-trees just over the fence from your apiary. Does he ever complain that the bees annoy him?"

"No: he has never complained of being annoyed; but when I first started in the business, and when an occasional swarm would cluster on some of his fruit-trees, he would watch—from a distance—and request me not to cut limbs unnecessarily; but when he found that I never cut a limb nor branch he became quite interested in the bees; and now, whenever he finds a swarm clustered he notifies me of the fact, but I never fail to present him with honey in such a case."

"Do your neighbors ever complain that your bees injure fruit, especially grapes?"

"Yes, a few years ago I had two neighbors who had a nice lot of grapes; and it being a very dry season, the grapes cracked open when ripening; and there being a dearth of honey at the time, the bees visited the grapes in large numbers, and were really a great annoyance. One of these men once spoke to me about it, asking me if I could not fasten my bees in their hives until after his grapes ripened and were gathered; but a few words of explanation convinced him that it would not be best for me to do so. He thought the bees punctured the grapes; and all I could say on that subject failed to convince him that they did not. I finally went with him into his grapery, where we watched; and by much watching and experimenting, I succeeded in convincing him that the bees worked on only such grapes as were already punctured or cracked open, caused by the severe drouth. I told him that if we could only have a shower, the trouble would be ended; and it so happened that it did rain the very next day, and sure enough the bees did not visit the grapes any more that season. This man is now a friend of the bees, and has never been troubled that way since, owing to the fact that we have not since happened to have a drought at that season of the year. The other neighbor, who, by the way, is of a very different temperament, said nothing to me about the bees working on his grapes, but tried to get even with the bees by destroying them. One morning he called to his nearest neighbor, 'Hill, come over here; I want to show you something. There. See those boards there? Well, now, you just keep quiet and I will show you how I fix Manum's bees that are eating up my grapes.' He had two boards, each four feet long, arranged fly-trap fashion, the inside of which was covered with syrup to attract the bees; and, slam went the boards; and then with a shingle he scraped off the bees. 'There,' he says to Hill, I shall keep that trap at work till I kill every bee Manum has got, unless they let my grapes alone.' It happened that Hill knew something about bees, and he laughed at this good man for his folly, telling him that, instead of doing me an injury, he was doing me a good service; because, as the honey season was over, I had many more bees in each hive than I wanted, and that those he was killing were the old ones that I wanted to get rid of, and, besides, that young bees were hatching much faster than he could kill the old ones. He advised him to talk with me on the subject. That day I chanced to meet Mr. Hill, when he told me what he had witnessed, and we had a good laugh over it. But I called on my good friend and tried to settle with him for the damage the bees had done, but he would take nothing. I explained to him as well as I could the condition of things, and related my experiment with the other neighbor that very morning.

This good man seemed to have gained new knowledge of things, and admitted that he had acted a little hasty. That evening I presented his wife a few boxes of honey, and in return he sent me a fine selection of choice grapes. Since then all has been peace and harmony between the bees and fruit-men in this place, so far as I know."

"Do the ladies near you ever complain that the bees trouble them while they are canning fruit, making pickles, etc.?"

"No particular complaints have come to me, and yet some of my neighbors have mentioned that, on such occasions, the bees would enter the house; but, surmising the cause of their intrusion, they closed the doors. But these instances are now very rare, as nearly every house is provided with screens, which prevent the bees from entering, as well as flies. Let me tell you, Mr. Larrabee, that I believe that I am in an exceedingly favorable locality so far as regards kind and sympathetic neighbors, for I have not, to my knowledge, a neighbor who is not interested in my success, for there is hardly a person of my acquaintance but that, when I meet him, inquires after the bees, and expresses a wish that I may be successful. I will give you the experience of one day with my neighbors, as I noted it down. In the morning I went to the office to mail a few queens, when I met a neighbor, who asked, 'Manum, how are your bees doing this season?' My answer, of course, was, 'Not very well yet.' 'Well,' says my friend, 'I am sorry. I hope they will yet make you a lot of honey. I have been thinking of you for some time, and wondered whether you were getting much honey.' In a few moments I met another neighbor who asked, 'Manum, are your bees doing any thing this summer?' 'Well, Mr. Wright, they are doing just about nothing.' 'Well, what is the matter? You have had several poor years now in succession, and I did hope they would do well this year. Do you salt them enough? I remember when I was a boy my grandfather used to salt his bees, and he said they worked better when salted.' The next person who hailed me was a lady. 'Mr. Manum, your bees must be making lots of honey now, for I see so many clover-blossoms everywhere; and yesterday there was a lot of bees getting honey from the clover on our lawn, and I forbade the children from playing there for fear they might disturb the bees, for I am so anxious that your bees do well for you this year, you have had such bad luck for a few years past.' On my return from the office, I harnessed a horse and started for one of my out-apiaries. I had gone but a short distance when I met a farmer who inquired about the bees much as the others had, and asked whether I thought bees would get as much honey from Japanese buckwheat as from the other varieties, and remarked that, if they could, he would sow five acres instead of one, as was his custom, and said that he thought that, inasmuch as my bees were a benefit to buckwheat, farmers ought to sow more and reap the benefit from the bees, and at the same time help me.

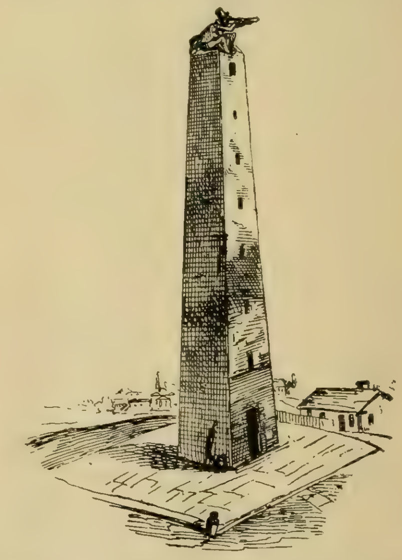
"I soon met another farmer who asked, like all the others, how the bees were doing, and then asked whether it would be any damage to me if he should cut his alsike clover, which I had induced him to sow, while it was in blossom. I told him, that undoubtedly it would rob the bees of so much pasturage, and, besides, it would damage him; for, unlike the red variety, alsike clover makes better hay if allowed to stand until nearly all the blossoms turn brown, because it is finer than red, and of such a nature that it is much hardier when allowed to mature; and, again, that, unlike red clover, it seeds with the first crop; hence, if allowed to nearly mature, the seed furnishes much additional nutriment; whereupon he decided to let it mature. On that day I met 11 persons who manifested a similar interest in my welfare and success, as did those whom I have mentioned. In fact, I do not know of a person of my acquaintance who is not friendly to the bee-business; hence, I say, that, judging from an occasional article that appears in the bee-papers regarding the enemies of the business, I feel that I have a favored locality in that respect, for I have most excellent neighbors."

Bristol, Vt. A. E. MANUM.

RAMBLE NO. 37.

THE BAY STATE APIARY.

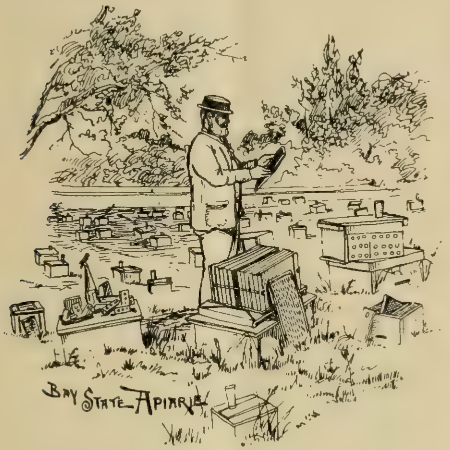
We reluctantly bade our Rhode Island friends good-by, and sped on our way toward the Bay State Apiary. Our route conducted us through the city of Boston, and here our patriotic blood became so stirred up that we lost our reckoning. But Boston people have erected a massive stone tower on Bunker Hill, where the traveler can climb up 294 steps and get a wide view. This view enabled us to get our reckoning again in a manner highly satisfactory. We immediately ran downstairs and followed our reckoning, and were safely landed in Wenham, about 11 o'clock. A street-car was standing near, and an inquiry elicited the information that Mr. Alley lived half a mile from the depot. We journeyed by street-car until the conductor pointed out the residence of our friend, and we were soon exchanging our identity with Bro. Alley. Our identity seemed to be satisfactory, and we were invited to rest a while in his den, and we gratefully accepted a rocking-chair. We found Bro. A. just giving the finishing touches to the October issue of the *Apiculturist*, and his letters and MSS. were in a rather promiscuous heap upon the table. We also noticed a large pile of "Thirty Years Among the Bees," ready to mail, besides quite a number of *Apiculturists*. There were also several crates of



BUNKER HILL MONUMENT; THE RAMBLER GETTING HIS EYE ON HENRY ALLEY.

fine comb honey and cans of extracted honey which had just been brought from a local fair which Mr. A. had just been attending. Both quantity and quality showed that Eastern Massachusetts had enjoyed a good honey-yield.

A call to dinner transferred our talk to the dining-room. While engaged in doing justice to Bay State substantials, who should come to share them with us but Bro. Pratt, of Beverly, Mass.? After dinner we all felt remarkably well and good-natured, and we adjourned to the bee-yard. Bro. A. had just put up his last shipment of queens; and as they were piled up nicely on the cover of a Bay State hive we brought our camera to bear upon them, Bro. A., and the queen-rearing portion of the Bay State apiary. He is manipulating a Bay State hive, and we caught a very good view. Forty full colonies are in the home yard, besides over two hundred queen-rearing hives. The little hives and tin feeders were scattered promiscuously, with entrances toward all points of the compass.



LAST SHIPMENT OF QUEENS FROM THE BAY STATE APIARY, SEPT., 1890.

We expressed a desire to see the yellow Carniolans, and were immediately shown a colony that would ordinarily pass for very good Italians. But these bees, when the hive was opened, showed all the traits of the dark Carniolans. No veil nor smoke was used. Quick motions near the comb or over the hive were not resented. As to honey-gathering qualities, we should think that Eastern Massachusetts is not the locality to test them for prodigious yields; but Bros. Alley and Pratt both have great confidence in the superiority of this strain over all others.

We were next shown the colony in which was installed the celebrated $100 queen. This colony had thrown off a swarm quite early, and during the season sixty frames of brood had been drawn from the parent colony alone for queen-rearing. But whatever prodigies the colony had done, we noticed that they were very active; and though it was during the last days of September, they were busy at work; and, allowing the Rambler to judge, it was the best colony in the Bay State apiary.

HOW ALLEY INTRODUCES A FERTILE QUEEN WITHOUT CAGING.

While talking about introducing queens, Bro. A. said he would show us how to do it. Taking a fine large fertile queen from a nucleus he stepped to a full colony, removed the cover, and dropped her, in an unceremonious manner, among the bees. We watched her a few moments. The bees were friendly, and she marched straight down between the combs, the reigning majesty. The colony had been queenless three days, and it was *just the proper time* to introduce her. Much earlier or much later than 72 hours would have resulted differently.

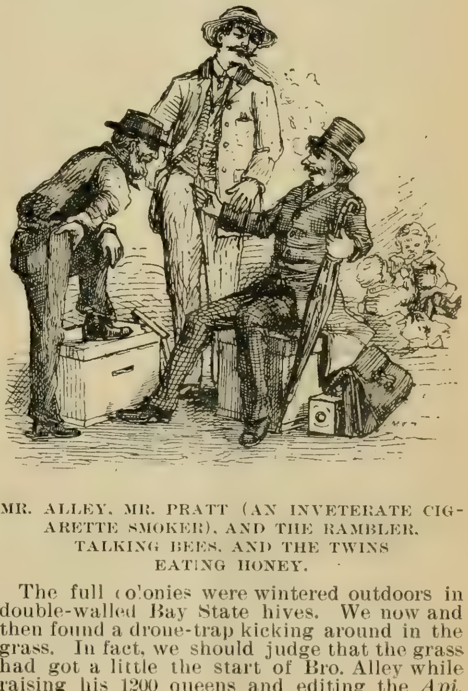
HOW TO INTRODUCE A VIRGIN.

We will now go with Bro. A. and introduce a virgin queen to a nucleus. The tobacco smoker is lighted, and the caged queen, perhaps just from the nursery, is taken to the queenless nucleus. A green plantain leaf is inserted in the entrance, the cover removed, and a couple of whiffs of tobacco smoke, and another as the queen is dropped, and the cover is replaced. We thought that was doing things quite rapidly, and removed the cover to look a little longer. Bro. A. says, "Wait a few minutes, and we will examine them again." He keeps a record of the condition of the nucleus, with a shoetack system. The Rambler will not undertake to describe the various positions, slants, and angles, and what they mean.

About this time we returned to the nucleus, and found every bee in the bottom of the nucleus in a stupefied condition; and when their senses returned, the virgin queen was accepted. The plantain leaf soon wilted, and the bees could pass to their work. It struck the Rambler all of a sudden that these 200 nuclei, so well stocked with bees, would make several good colonies, and we asked what was to be done with them.

"Oh," said he, "some frosty morning I will brush the bees off into the grass. It doesn't pay to unite and feed up. The bees usually die during the winter, and they might as well die now, and save all of the bother. I purchase bees in the spring to supply the waste."

The little combs are packed away in barrels, and securely headed up to keep mice away from them.



MR. ALLEY, MR. PRATT (AN INVETERATE CIGARETTE SMOKER), AND THE RAMBLER, TALKING BEES, AND THE TWINS EATING HONEY.

The full colonies were wintered outdoors in double-walled Bay State hives. We now and then found a drone-trap kicking around in the grass. In fact, we should judge that the grass had got a little the start of Bro. Alley while raising his 1200 queens and editing the *Api.*

His apiary was, however, about as tidy as the average run of bee-yards where there is much work done. We have noticed that these gilt-edged apiaries are the ones that do not bring in a large amount of surplus cash.

While in the Bay State apiary we did not talk so fast and get so absorbed as to fail to notice a very pleasant feature in the apiary. Two wee bits of granddaughters were upon his lap or following his steps when at a safe distance from the bees. They were indulged with sauce-plates, and spoons and honey; and while we were talking bees, the honey was distributed in various directions. Bro. A. is positive in his views, and believes his method of queen-rearing is *the* method. His claim, that queens should be reared from the egg, though not much discussed at the time, had the effect of setting the Rambler to thinking about the matter, and the results of our cogitations will be given in our next. Rambler.

[Now, look here, old friend; while we are greatly rejoiced at this pleasant glimpse of friend Alley's place of abode, when you tell us you "ran downstairs" on Bunker Hill monument we think you are getting decidedly in the way of skipping along almost too fast. I have been up and down those "stairs," as you call them, myself, and I did not feel very much like running. In fact, I sat down and blowed several times between the top and bottom. I am very glad if you can see friend Alley's ranch from the top; but when I was there I did not know of friend Alley's place nor about bees either. In my next visit I will be sure to hunt him up—yes, even if he does, as I have heard, manage to get a good deal of tobacco out of the way. While we are in the open air, I suppose I should not mind it very much. That idea of a plantain leaf for closing an entrance is certainly unique. By the way, didn't I have a little hand in that discovery? You know I told you that Dr. Miller threw some green leaves on the top of any hive that needed attention. If they forget to remove the leaves when they go away, the leaves dry up and blow away. In any case, they know at a glance (by the looks of the leaves) about how long ago the mark was made. Now, then, if we wish to close an entrance, say for a few hours, a green leaf will fill the bill. In regard to introducing a queen by just letting her loose, I suppose some of you know you can do this at almost any time, about three times out of four. When honey is coming briskly, and the colony has been queenless long enough to start queen-cells, we can do it certainly nine times out of ten. I hope friend Alley will excuse me for remonstrating against brushing the bees off on the grass. Brush them into a hive, give them a comb or two, and some sort of queen, and let them be happy while they live. Keep them, like the old horse, for the good they *have* done. We do not like your reflections on gilt-edged apiaries, exactly, friend R. It is true, there are apiaries where the gilt-edged feature is carried to extremes. I have seen some of them myself—some of those professional men, for instance, who have lots of money. A real nice attractive apiary wants to be the work of somebody who has to scratch and scrape, just a little, to make both ends meet. This will keep out of sight superfluities (just for show), and yet have things neat and in order, arranged so as to give the greatest facilities for rapid work. I am very glad of that glimpse you give of the twins. We would not have missed them for any thing. By the way, we wonder how *many* of the veterans have arrived at the dignity of being called "grandpa" by some little "new edition." Friend Alley, we lift our cap and extend our congratulations.]

HOW TO BIND A VOLUME OF GLEANINGS.

PLAIN DIRECTIONS, AND HOW TO DO IT SUBSTANTIALLY AND NEATLY.

I have just finished binding the last volume of Gleanings; and the thought comes to my mind, "What do its ten thousand readers do with the back numbers?" To many of them it is no doubt as interesting, entertaining, and instructive, as it is to me; and I wonder how many preserve them as carefully as I do, and how they do it. Some, no doubt, take them to a book-binder, have them bound substantially, and then give them a good corner of the book-case or library. Another way is to lay them aside, on a shelf, or in a drawer, where they will be handy to re-read, or for reference. But we all know what becomes of unbound journals and magazines—or, rather, we *don't* know. They are mislaid, borrowed, and never returned—disappear mysteriously during some house-cleaning raid, or are carried out of sight and out of mind to the garret or lumber room. Another method, *my* way, and so I think it a good one, is to bind them in tough paper covers at home; and, with your permission, I will tell your readers how to do it neatly, cheaply, and well.

You will need some brass wire, as heavy as or a little heavier than a stout pin; a hammer, an awl, a file, or a pair of snips to cut the wire; pliers to bend it; paste, and some heavy tough paper.

Gleanings is ten inches long. Get a piece of soft wood that length, an inch or more wide, and a quarter of an inch thick. An inch and a half from the end, and one-fourth inch from the edge, make a hole through this stick with a small gimlet, or with the awl; and, a half-inch further on, another. Make a like pair at the other end, and another pair at the middle. Now take the cover and advertising pages, and the little wires that hold the leaves together, from the issue for Dec. 15. Lay it, last page up, on a soft board; lay the stick on it, the edge with the holes in it parallel with the back of the magazine; and, putting the awl in the holes in the stick, punch similar holes in the paper. Lay it off, last page down, and treat Dec. 1st in the same manner, and so on to July 1st. Twelve numbers make a handy volume to bind or to read. Now cut three pieces of the wire, three or four inches long, and bend them in the shape of a double-pointed tack, the points half an inch apart and an inch and a half long. Cut two pieces of the heavy paper about 7½x10½; and, three-fourths of an inch from one edge, punch holes like those in the journals. Put the bent wires in the holes in one piece, and lay it on the table, wire points up. Then take the issue for Dec. 15th and put the wires through the holes in it, and so on until you have as many numbers as you wish to bind in one volume. Put the other piece of heavy paper on top of these, and hammer the whole down around the wires.

Don't be afraid to strike hard; get it solid, and then cut the wires down to within one-fourth inch of the book, and clinch them, bending the points toward each other. Now paste the extra half-inch of the covers over the back of the book, first one; and when that sticks well, the other; and across the back, and extending an inch or two on the covers, paste a strip of thin linen. Take the cover pages of Gleanings for July 1st, and cut off the last leaf close to the print, and another cover cut close to the print of the first page, and paste these over all, putting on the back cover first. Now put it under a press of some kind until dry; then if you want to trim the edges, and can't get to some printing-office where they always have machines to do this work, clamp the edge tightly in a vise, with a smooth straight-edged board between the jaws and the paper, and with a sharp draw-knife you can shave the solid paper almost as easily as wood. But remember that I said, a *sharp* draw-knife.

If you have handy fingers, and follow these directions carefully, I am sure you will turn out a job you will be proud of; in any event, you will have your favorite GLEANINGS in a shape to make reading and reference easy.

A good paste is gum tragacanth, softened in pure water, with a few drops of spirits of camphor or carbolic acid added, to keep it from molding. It should have only enough water to thoroughly soften it. E. J. BAIRD.

Orlando, Fla., Jan. 10.

[The method you describe is the same as that used by professional book-binders on books bound in paper, with the exception that they employ machinery, and you make use of common simple tools in the possession of most bee-keepers.]

PLANNING.

STUDYING OUT PROBLEMS IN BEE CULTURE WHILE YOU SHOULD BE LISTENING TO THE SERMON.

I hardly know whether to say that planning is one of the inalienable rights or one of the essential requisites of a bee-keeper. I have sometimes thought I should like to have every thing settled, so that I could know just what was best to do in every thing, and have no more studying or planning to do than a teamster hauling cordwood. But I don't know that I'd be happy then. I'm afraid I'd be planning how to have something else to plan about.

When do you do the most of your planning? I think a great deal, if not the most of the planning of bee-keepers, is done in bed. I judge so from so often hearing them talk about lying awake nights figuring over something, and also from the amount of night planning I have done myself. When is your best time for planning? that is, when do you seem to do the quickest and clearest work at making plans? I don't think I can answer that question so well for others; but for myself, to be entirely candid about it, my mind seems to be in the best shape for it when sitting in church trying to listen to a sermon. Please don't understand me as recommending that time for you to do your planning, nor even as saying that I ever deliberately sit and consciously spend my time planning through a whole sermon. Ordinarily I give the sermon my whole attention; and I think my pastor, if asked, would say that I was one of his helpers by keeping my eyes steadily fixed upon him. But suppose some bee-keeping problem has been in my mind for several days. I've been working hard upon it, sometimes thinking the answer just within reach, then finding myself overcome by some new difficulty. Saturday night finds me still working on it; and after going to bed I keep turning it over in my mind until I drop asleep. Perhaps I wake up in the night, and the first thing that comes in my thoughts is that problem. Just then the question comes, is it before or after 12 o'clock? in other words, is it Saturday or Sunday? If the clock doesn't happen to strike about that time to settle the question, I conclude it's better for me to go to sleep anyhow—if I can. If I wake in the morning before it is time to rise, up comes that problem; and after making an effort for some time to think of something else I arise in self-defense and take to some good reading. Then I get along perhaps all right until I get to church and get settled to listen to the sermon. Directly some word switches my mind off upon a track that leads directly to that problem, and, before I know it, I am chasing it up full speed, and am surprised to see how easily I can get over some of the difficulties that before seemed insurmountable. In a minute I recollect myself with "Hold up, there! I thought you were listening to the sermon!" and the reply comes, "Well, isn't it too bad not to follow it up when following it up a little further would finish it up, I feel pretty sure, in nice shape?" But I bring myself up with a round turn, and, with perhaps an occasional slip, let the problem alone till Monday morning, when I am likely to find myself in pretty good shape to handle it.

Now, I have a word of advice for the younger members of the fraternity. You are likely to do a great deal of planning, and more depends on the quality than on the quantity of such work. Don't decide, from what I have said, that Sunday is a better day for planning than any other. It isn't. Why, then, did it seem so in my case? Simply because for a time my mind had been kept free from that kind of work, and was rested. If I should keep to work right on through Sunday, the same result would not follow. The point I wish to make is, that you are not wise to hold your mind too closely to any plan till it is too tired to work well. Many a night I have lain thinking till too tired and drowsy to think very much about any thing, and then, having a sort of feeling that the thing must be settled then and there, have roused myself by a strong effort, only to find that I was then simply wakeful, without the power to do any good headwork.

On the whole, I think you will be the gainer to refuse resolutely to do any sort of planning after you go to bed. Just for the time, you may seem to lose by it, but not in the long run. When you find your mind tired, stop, and go at it some time again. Don't try to be too abstract in your planning. If you are planning to do something with a hive, don't tire yourself trying to imagine how such and such things will look when you have placed them so and so. Get the things right before you and it will be easier and better for you.

Before you do a great deal of planning, read up what has been done by others in the past. Not long ago a beginner showed me a house which he had built for wintering bees, and asked my opinion about it. It was nicely built, costing about $70.00; but if he had possessed himself of the books a bee-keeper ought to have, and also the back numbers of the leading bee-journals, he would have seen that he had nothing new or approved. C. C. MILLER.

Marengo, Ill., Jan. 17.

[Well, well, old friend: and is it really true that you are fighting temptation so exactly along the same line that I have been for some time past? It has been one of the mysteries to me, why my mind (or, rather, my "planning machinery") should always start with such tremendous energy just as soon as Sunday morning comes, and especially when the sermon commences. I have a great many times noticed that, when older people want to talk, say at the breakfast-table, it is just the time when the little ones, and perhaps the baby who can not talk at all, begin their prattle; and I have seen canary birds that would be as quiet as you wish until somebody commenced conversation, then they would almost split their little throats in the effort, as it appeared, to drown the conversation. The business of talking seems to be infectious. Well, in studying the matter over it has occurred to me that this involuntary thinking machinery is like the canaries and the little household prattlers. Just as soon as something of importance is going on, it just puts in its level best to be heard; and in this matter of the worship of God I am sure that *Satan* makes an effort to divert our attention and to draw us away, if possible, from holy things. *He* can not bear to see us take up the Bible. He will keep us away from church if he possibly can; and he will help us to make all manner of excuses, and he does not give it up even then. If he finds we are bound to go to church *any way*, he follows up, keeps close at hand, and just as soon as the man of God commences something that is really spiritual and elevating, then he pushes in week-day traffic. He holds up a thousand and one allurements to draw us away, if it be a possible thing, from the subject in hand, and to make us lose the great spiritual truths that have been so carefully prepared to do us good. Many and many a time I have with resolute will put away greenhouses and schemes for gardening during the Sabbath. I have said to this planning machinery, "Now, look here, you just shut up and keep still. When it comes Monday morning we will have a good time in working out these problems, and perhaps have a good time in putting them in practice; but not *another word* of it on God's holy day." Why, I have sometimes even longed for Monday morning, that I might plan and build with a clear conscience. When Monday morning came, however, the thing that looked so enticing during the sermon had little or no attractions at all, and possibly it was all dropped until *another* Sunday morning, when it was sure to start out anew. Sometimes I have been foolish enough to follow these plans out, at least somewhat on Sunday; but they never turned out well. If we are to enjoy God's spiritual gifts to the fullest extent, we must obey his holy command, and forbear not only physical but *mental* work on the Sabbath. I confess that I feel more encouraged to fight these battles when I know that somebody else has had temptations along the same line; and who knows but there are others besides Dr. Miller and myself among the readers of GLEANINGS who have like trials and temptations? Let me say to such, "Be not weary." In the 7th chapter of Revelation we have the following words: "These are they which came out of great tribulation, and have washed their robes, and made them white in the blood of the Lamb. Therefore are they before the throne of God, and serve him day and night in his temple."]

MORE ABOUT THE HONEY FROM THE CACTI.

CACTI-BLOSSOMS AS LARGE AS COWBELLS, AND HONEY BY THE SPOONFUL.

In the Dec. 1st issue of GLEANINGS, p. 858, under the heading of "One of the Cacti," Prof. Cook asks, "Who will inform us in the matter?" The readers of GLEANINGS would not, as a whole, be any more than amused were I to write up the cacti (the 31 varieties) of Arizona, and the amount of honey secreted in the flowers, from the fact that a true statement would simply be taken as a wonderful exaggeration. B. F. Johnson, of Tempe, now a resident of Mexico, tells me that the cacti in Mexico have more honey than ours in Arizona. Mr. Editor, you have long been acquainted with the pen of Mr. Johnson; and as to his truth and veracity, I leave the readers of GLEANINGS to judge, when he tells us that in Mexico some of those cacti have a bloom as large as a cowbell, and honey lying in that bloom till you can gather it up with a teaspoon. It won't be long before the readers of GLEANINGS will read, "Pure cacti honey, from the deserts of Arizona," on the eastern market. But we expect trouble in getting it on the markets, as it grains in the bloom. It grains in the hive too; and when you people strike it in the condition of Yankee maple sugar in the can, you will cry out, "Adulteration !" But, buy just a little; try it; and next time you will hunt the market for Arizona cacti honey. GEO. K. MILLER.

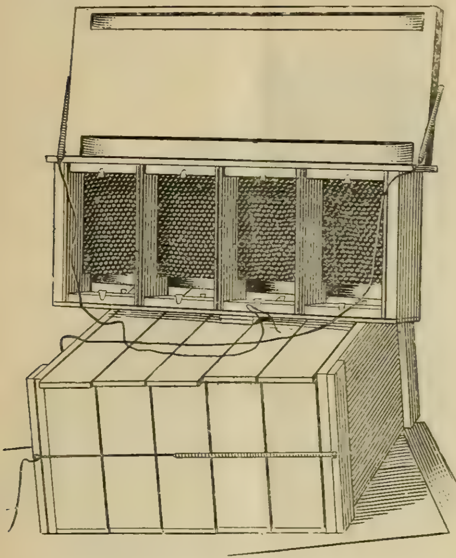
Tempe, Ariz., Jan. 11.

[Thank you, friend M. In passing through Arizona, nothing, perhaps, interested me more than the wonderful class of vegetation you have mentioned. It was not the time of flowers when I was there, but the fruits not only interested me but refreshed me greatly. I looked over in the direction of Mexico, and longed for liberty to go down and investigate. Providence permitting, may be I shall some time have that pleasure.]

SURPLUS ARRANGEMENT.

DOOLITTLE'S METHOD OF SECURING COMB HONEY.

As we go back over the past in memory, we can not help seeing the great strides made in bee-keeping during the last thirty years. We have many new things to-day that were hardly thought of at that time, such as comb foundation, the honey-extractor, queen-excluding metal, etc., which are often mentioned as the "great advancements;" but it seems to me that the improvements regarding some of the things that were used thirty years ago should call forth our admiration fully as much as do the many new things. I think, in no other one thing has the advancement been any greater than in our mode of taking comb honey. Thirty years ago the smallest section, or honey-box, as it was then called, held six pounds of honey, or thereabouts, the same having three combs. Soon followed the two-comb box, then the one-comb box, next the two-pound section, the 2½-pound section, the one-pound, and finally from the half-pound down to the Harmer two-ounce package, all coming in rapid succession, when a want for any or all of these was felt. Well, with the advent of sections came the want of something to hold them, keep them clean, etc.; and many have been the inventions for this purpose, such as wide frames, single and double tier; honey-racks, crates, T supers, etc., all of which have had their advocates. After testing many of these different arrangements I decided on the one-tier wide frames as being the best; and in using them I adopted the plan known as "side and top storage combined," with which I was very successful for many years. I never did like the tiering-up plan, used so successfully by many, for the reason that, in this locality, it so often happened that the season would close before many if any of the sections were finished, leaving me with a large lot of unfinished sections on hand, with few if any completed for market. With the side and top storage plan I could take the sections off the top as fast as finished, raise the partly finished ones from the sides to the top, and, by putting in empty sections at the sides, keep the bees on new work there and finishing it on top. When the season drew toward a close, no more was put in at the sides, and thus I had nearly all the sections which were used during the season finished at the end of the honey harvest. In this way remarkable results can be secured; in fact, I do not believe there is any other plan known whereby as much nice white comb honey can be obtained as by the above, where any one has the time to carry it out; but it requires time and close attention to all of the minute details connected with it.



DOOLITTLE'S SURPLUS ARRANGEMENT.

While I sometimes think that enough more honey can be obtained to pay for all this extra trouble, yet of late I have adopted a somewhat different plan whereby nearly if not quite as much honey can be obtained with much less work; and for want of a better name I have called it "the lateral plan." Before adopting this lateral plan I obtained and tried nearly all of the different cases and supers in use, and, after a careful testing of the whole, I came to the conclusion that, taking all things into consideration, this had more advantages and fewer disadvantages than any of the others. That the reader may know just how the wide frames are used by this plan I have had an engraving of them made, so as to save the talk necessary in telling them what I wish to.

My hives are all chaff hives, and I use on each, when working for surplus honey, a queen-excluding honey-board, which extends out over the chaff at either side of the brood-chamber, so that I can put on from three to ten of these wide frames, just as I wish. On most of my hives I place five wide frames at the beginning of the season, fixed and held together as shown in the lower part of the cut. The center wide frame contains sections with combs left over from the previous season, used as "bait" sections; and as these go directly over the center of the brood-nest, the bees go to work in them at once as soon as there is any honey coming in from the fields. As soon as the bees get well to work in these five wide frames I load my wheelbarrow with wide frames, having sections filled with foundation, as shown in the center of the engraving, and, arriving at a hive, I unwind the string from around the flat-headed nail, shown at the left of the lower part of the engraving, which allows the coil-wire spring to assume the shape you see them at the top part of the cut, when the wide frames can be handled as I please. Instead of handling them as some do, putting the added wide frames between the others, I simply take off the side board and add wide frames to each side to the amount needed, when the side boards are placed back, the springs drawn to a strong tension, the strings wound a little more than one turn around the nail-heads to hold them, when I am ready to move on to the next hive. In a week or so I start out in the same way again. I now find from one to five frames of sections finished, out of those put on at first, which are taken off and the bees shaken off the four sections by taking hold of the projecting ends of the wide frames, the same as they are shaken off from a brood comb. The remaining wide frames of unfinished sections are now drawn together over the center of the brood-nest, when the necessary number of wide frames of sections is added to each side. In this way I keep working till the season begins to draw toward a close, when, instead of adding more sections at the side, the unfinished ones are drawn together, so that at the end of the season I have no more unfinished sections than I wish as bait-sections to commence the next year with. In this way the bees are kept at work in a natural manner, building their comb outward all the while, and finishing their work at the center, which has a tendency to reduce swarming, and give a greater yield of finished honey than by any other method with which I am acquainted. The plan also allows of adjusting the amount of surplus room to the wants or size of the colony, so that no colony is discouraged by too much surplus room being given at first, and none are crowded for want of room. It also keeps the wide frames drawn tight together at all times, so that, as the lumps of propolis soften with heat, which may be on the wide frames or sections, the slack is always taken up; and they can be tiered up by those who wish to tier up, by simply making suitable slots in the tops of the wide frames, like those in the bottom—reversed or handled as a whole, cost little if any more than any good arrangement for surplus comb honey; and as a whole it takes no more time to prepare and manipulate them and the sections than it does any other *first-class* arrangement; while the sections are kept almost entirely free from propolis. If the reader will refer to the upper part of the cut he will see how the propolis trouble is obviated on the outside of the outside tier of sections, where the greatest annoyance comes by way of propolis, where the outside sections are clamped against any flat surface. A rubber band or a wire, or even a string, can be made to answer in place of the springs; but as they cost only 25 cents per dozen, and are so much better than any thing else, they are much the cheapest in the end. I still use 1¼-pound sections, the same being two inches wide, and glass all my sections. This will help the reader to understand the cut better. As long as these 1¼-lb. glassed sections find a ready sale in our Eastern markets at the same price as one-pound sections unglassed, I shall continue to use them; but I am always ready to accept any real improvement as soon as I find it out.

G. M. DOOLITTLE.

Borodino, N. Y., Feb., 1891.

[Friend D., you will, by your plan of working, get nicer honey than by the usual way of letting the cases remain on the hive until they are all sealed. But you will also have more labor, I think, than by some of the other methods that do not give as nice a product. Then the question is, "Does the extra price received pay for the extra amount of work?" For a market that wants nice glassed sections, I am inclined to think it does; and if you can arrange things so as to make your way of taking out all sections, as soon as finished, but little if any expense, more than the other way, you certainly are ahead. I believe the best results will also be obtained by having a spring, or some equivalent, to constantly pull the sections (and wide frames if they are used) tight up against each other.]

THE SPIDER-PLANT.

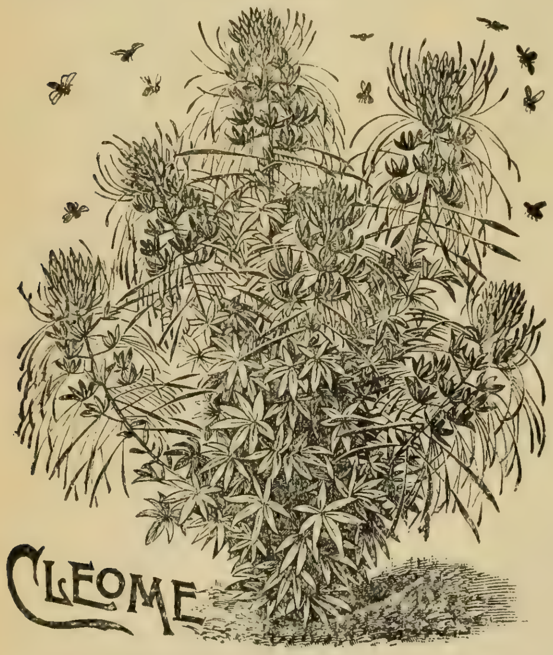
NEW ENGRAVINGS FOR THE A B C OF BEE CULTURE.

By Ernest R. Root.

While looking over the seed catalogue of one of the prominent seedsmen, W. Atlee Burpee, we ran across a very accurate engraving of the spider-plant—the best representation that has ever been made, so far as I know. As we are now revising the A B C of Bee Culture, making new engravings and such other improvements as will make the work more valuable, we concluded to re-engrave it; and for the benefit of our journal readers I here submit it.

The bees on the wing, going to and from the blossom, is characteristic of their behavior toward the plant. But there is just *one* thing that the cut does not show, and that is the little drop of honey sparkling in the blossom, but which the reduced size makes it impossible to show.

Aside from being a honey-plant, spider-plant is one of the most ornamental shrubs ever placed in a flower-garden, and so advertised in Burpee's catalogue. As we state in the A B C book, it is not of sufficient value to a bee-keeper, however, to warrant planting them on a large scale. But a few of them will adorn the dooryard, and give you a chance to see how the bees fairly swarm upon the blossoms. Those large crystal drops of nectar and the greed of the bees in the early morn, is a sight to behold.

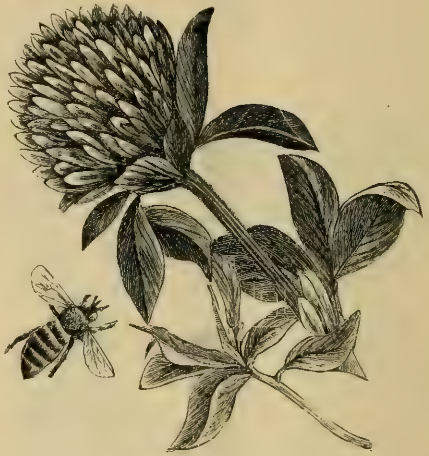


CLEOME PUNGENS, OR SPIDER-PLANT.

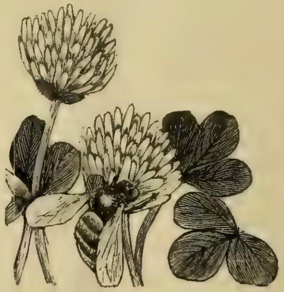
RED AND WHITE CLOVER.

☞ While I am about it, I might as well present you with two engravings that we have adapted for the A B C book.

If we could give the appropriate colors to the blossom and stem, we should have a well-nigh perfect representation of our common red clover. The stem has the usual characteristic fringe of hairs, and the shape of the leaves is also characteristic. It may seem to some of our readers almost unnecessary to represent any thing so common; but there are places where even red clover does not grow; and for the benefit of the bee-keepers who are unacquainted with it, I am glad to show them what it looks like. Perhaps I should remark that peavine clover is just the same, only the stems are much longer.



COMMON RED CLOVER.



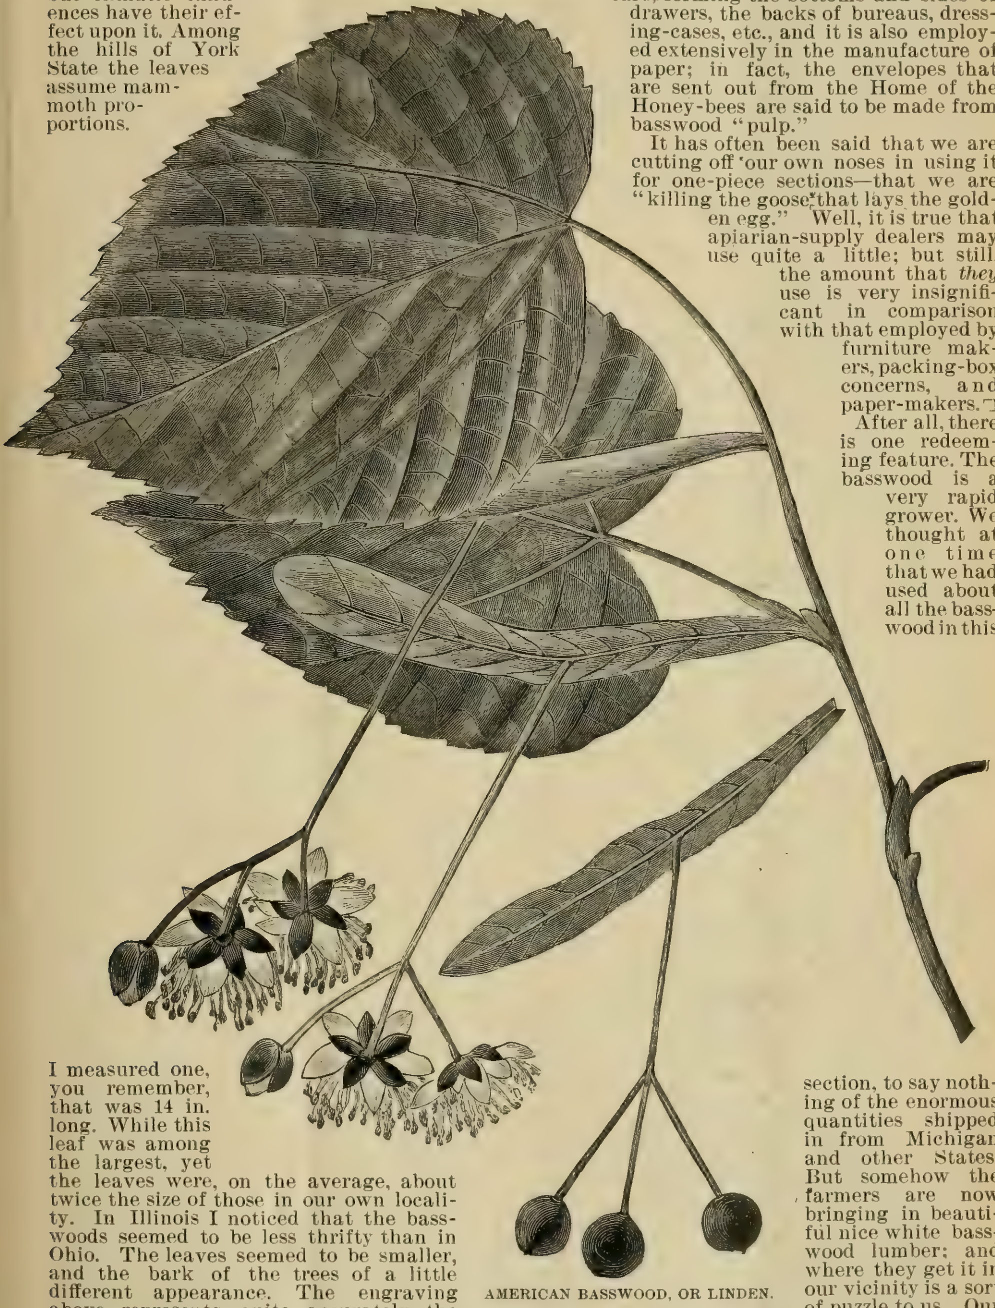
WHITE CLOVER.

☞ This engraving shows the most valuable of all honey-plants to the bee-keeper. Without it, bee-keeping in the United States and Canada would assume hardly half its present proportions; and but for it we should be without one of the finest honeys in the world—the very finest, if we except the alfalfa. Our artist, it seems, caught a bee while in the act of appropriating the delicious nectar.

BASSWOOD, OR LINDEN.

By the by, we have also had another engraving of basswood made expressly for the A B C book; and its importance as a honey-plant is second only to the white clover as above.

Our artist, who was looking over some beautiful plates in a standard work in one of our public libraries, accidentally ran across a representation of basswood. It was so accurate that we instructed him to copy it, as faithfully as he could, by a wood engraving, and we give the result below.



AMERICAN BASSWOOD, OR LINDEN.

The same thing is what the Canadians call "linden," and we across the line, as a general rule, term it *basswood.* There is no difference, but climatic influences have their effect upon it. Among the hills of York State the leaves assume mammoth proportions. I measured one, you remember, that was 14 in. long. While this leaf was among the largest, yet the leaves were, on the average, about twice the size of those in our own locality. In Illinois I noticed that the basswoods seemed to be less thrifty than in Ohio. The leaves seemed to be smaller, and the bark of the trees of a little different appearance. The engraving above represents quite accurately the typical forms, however. The European variety has smaller leaves, and differs from *Tilia Americana* in a few other minor respects.

It is rather to be regretted that this tree is not more plentiful than it is. It is one of the main stays, where it grows, of the honey-producer, and one of the most valuable woods in manufacture. It will hardly do for outside exposure to the weather; but it is admirably adapted for packing-boxes, and is used in *immense* quantities in the manufacture of furniture, forming the bottoms and sides of drawers, the backs of bureaus, dressing-cases, etc., and it is also employed extensively in the manufacture of paper; in fact, the envelopes that are sent out from the Home of the Honey-bees are said to be made from basswood "pulp."

It has often been said that we are cutting off our own noses in using it for one-piece sections—that we are "killing the goose that lays the golden egg." Well, it is true that apiarian-supply dealers may use quite a little; but still, the amount that *they* use is very insignificant in comparison with that employed by furniture makers, packing-box concerns, and paper-makers.

After all, there is one redeeming feature. The basswood is a very rapid grower. We thought at one time that we had used about all the basswood in this section, to say nothing of the enormous quantities shipped in from Michigan and other States. But somehow the farmers are now bringing in beautiful nice white basswood lumber; and where they get it in our vicinity is a sort of puzzle to us. Our superintendent, Mr. Warner, assures me that at least some of this lumber is from a second growth of trees that sprouted ten years ago from the stumps of old trees—said trees having been cut for us ten years ago. *If* basswood will replace itself in ten or even twenty years, so that it can be used again for lumber, there is yet hope that it may continue to bless the bee-keeper.

There is one thing certain—that basswoods do not do nearly as well away from the shade of other trees. In our basswood orchard there are trees that are protected by some large oaks, that made a growth from three to four times as large as those out in the open field. Those trees that are in the shade of our factory are much more thrifty than those along the road-side without the shade of buildings or of other trees.

THE NEW YORK STATE BEE-KEEPERS' CONVENTION.

NOTES, BY ERNEST.

On the morning of the first day it rained furiously, and the streets of Albany were literally puddles and streams of water—so much so that it was very difficult for a pedestrian to make his way from one point to another without getting wet feet. When I registered at the Globe Hotel I looked to see whether I could find the names of any bee-keepers I knew which were recorded before mine, but nary a one. I was afraid the large amount of rain the night previous would dampen the spirits of a great many who possibly had thought of coming. In fact, after breakfast I sat down in the hotel and waited for the bee-keepers to come in.

While thus employed, my thoughts reverted to the time when, last fall, I had arrived at this very same hotel after a bicycle run of 50 miles. I came in, I remember, muddy, wet, and tired, and my clothing was somewhat torn by the effects of that bulldog encounter, an account of which I have already given. For curiosity I thought I would ascertain whether the clerk remembered me. "Oh, yes!" said he; "you are the chap who came in so dilapidated from that fifty-mile run through the mud from Durham. I could not forget that."

He was very glad to see that I had survived the journey, and inquired whether I expected to take a similar run again.

"Never," I replied, "over such roads, nor through such mud, and, much less, by the house of the box-hive bee-keeper who owned that ferocious bulldog."

After a pleasant chat with the clerk I asked where to take the electric motor over to Troy. "Just a couple of blocks down the street." A ride on the electric car brought me to Troy. I made a short visit with relatives, and then returned to Albany and thence to Agricultural Hall. I inquired of the janitor where the bee-keepers' convention was. *He* hadn't seen any bee-keepers. He was told that they were to occupy *that* hall, pointing to an unoccupied room on the second floor. As I looked out on the streets running with water, I concluded that York State bee-keepers had become discouraged—even the president and secretary. Pretty soon, in came a gentleman, and after a little I began to inquire whether *he* knew any thing about a *bee*-convention in that building. No. He had been looking for the same thing all the afternoon. We "exchanged our identity," as the Rambler puts it, and fell to talking about bees, as to how they would winter, etc. I am such a poor hand to remember names that I can not now even remember who he was. "At any rate, I wonder what is going on in that room down there," I said, pointing downstairs. "I saw a couple of men go in a moment ago." I inquired of the janitor, who said it was an *agricultural* meeting. "I don't care very much about agriculture," said I, turning to my friend, "but let's go in and see what they are doing." Cautiously I opened the door, and, presto! there sat President Elwood in the chair, the secretary at his table, and a whole convention of *bee-keepers*. In various parts of the room were familiar faces whom I first met on my bicycle tour. My first thought was, "Why in the world didn't you people have a sign out and let folks know where you were?" I learned afterward that the place of meeting had been changed to another room—a room that had previously been occupied by an agricultural meeting; hence the janitor's mistake.

ARTIFICIAL PASTURAGE.

I arrived just in time to hear the discussion in regard to artificial pasturage. Among the plants discussed were the Chapman honey-plant, alfalfa, and sweet clover. The reports in regard to the first named were not very favorable. It seemed to be remarkable as a yielder of nectar, but its difficult propagation renders it impracticable for bee-keepers at large. George H. Ashmead had sown the Chapman honey-plant seed broadcast by moonlight.

"Why did you do it after dark?" some one asked.

"Oh! I did not want everybody to know what I was doing. It has not been called a bad weed; but some folks, if they had seen me sowing it, would have declared that I was sowing something that would work mischief to the farmers. But there was not one of those seeds that ever came up."

Mr. Thomas Pierce, of Gansevort, had tried sowing sweet clover, but none of it came up. Referring to the moonlight sowing, he banteringly said he would have some compunctions of conscience. That did not distress our friend Mr. Ashmead at all. He sowed upon waste places. He knew that the plant was not a bad weed, and he was not going to give his neighbors even a *chance* to think so. In regard to sweet clover, he had seen dirt thrown from the bottom of a well 30 feet deep, and sweet clover and mustard started from it.

The discussion then turned to alsike. In some parts of York State the farmers were introducing it, at the advice and suggestion of bee-keepers. In some cases they like it, and in some they don't. Where they did not take to it, it was ascertained that it grew up rank, and then rotted and died. It was recommended by some that it be sown with timothy or red clover. It is then not apt to lodge, and it makes a fine growth. Testimony was not wanting, to the effect that it is a splendid honey-plant—superior to ordinary white clover; and, as somebody said, "Bees work on it immense."

George H. Ashmead said that the farmers were going back on alsike in his locality. They complain that there is no after, or second growth. He thought that, if he could get them to sow it early enough, they would have two crops. Another thing, farmers complain that alsike turned their butter white. They had tried it, pasturing their cows two weeks on alsike and two weeks on white clover. The alsike, every time, they reported, would turn the butter white. When cows were pastured on common red clover the butter resumed its natural color. But there was one strong point; and that was, that alsike hay will not give horses the heaves as does red clover. Alsike has no fine fuzz that rattles down through the hay.

J. C. Stewart sells alsike seed to farmers, and distributed Mr. Newman's alsike pamphlets; and he discovered that the pamphlets helped to sell for him a good deal of the seed, besides giving him a little larger percentage of honey.

It was generally agreed, that, where farmers do use it, they regard it as the finest hay in the world. Mr. West said that his cattle would paw through the snow to get at it—a thing they would not do for any other clover or vegetation.

Referring to the scattering of seeds by the roadside or upon other waste places, President Elwood thought, as a matter of expediency and abstract right, we should be careful not to scatter upon the lands of others. We have a perfect right to do it on our own ground.

Somebody asked why clover seemed to yield honey at some times and not at others. Mr. W. L. Coggshall said that, if the atmosphere is right, we get honey; but if not, we do not, that's all.

Evening Session, First Day.

The matter of the use and abuse of foundation was brought up. Some argued that we were using too much, and that only starters, even in the brood-frames, were more profitable. There were not wanting others who insisted that they wanted full sheets every time. Mr. Ashmead thought that a good deal depends on how we work the bees, and the time of year in which the foundation was built out.

WIRING FOUNDATION.

As is usually the case, a good many wired their combs and they could not get along without it; and a good many did not wire, and could not see the need of it. The latter, as a general rule, seemed to be those who do not move their bees very much. W. E. Clark wired his frames horizontally. I asked him how it could be done, and not have the combs wavy. W. L. Coggshall replied by saying, "Don't stretch the wires too tight."

Our genial friend Mr. J. VanDeusen, of Sprout Brook, N. Y., who turns out that beautiful flat-bottomed foundation, was present, and he was called upon. He did not see the need of wiring *frames* at all; but he would use the light-weight brood foundation wired—that is, wired in the foundation. This prevents all sagging, and his customers, as a general rule, seem to be pleased. I noticed that a good many nodded assent, and I was surprised that there were so many large bee-keepers who use the flat-bottomed article. They like it, and prefer it to the natural base.

The discussion finally turned as to how to fasten foundation into sections. Almost every bee-keeper had a little different method, and *his* method, of course, was the *best*. After resolving it down, I found that the methods of all could be classed under two heads—those who use the melted-wax plan, and those who use a machine whereby the edge of the foundation is pressed into the wood. W. E. Clark, of smoker fame, had bought one of Bro. Root's Gray machines. He liked it very much. He subsequently purchased one of his improved Clark machines, and that was very much better yet. This machine was simply perfect, and with it he could put in foundation as fast as he could count.

Mr. Thomas Pierce, N. D. West, and quite a number of others, used the melted-wax plan, and they could do it very rapidly. They did not see the need of any machine to do it with. They just dipped the edge of the foundation into some melted wax, and then quickly set it right down in the section. Mr. Charles Stewart had used both the improved Clark machine and the melted-wax plan. He had got well used to both ways, but preferred the melted-wax method. He could do it a good deal faster and a good deal better. George H. Ashmead and several others nodded assent.

Some one asked whether the three-cornered starter was as good as full sheets. W. E. Clark answered that "climbers," as they are called, are not as apt to be built clear out to the edges of the sections as full sheets of foundation. There seemed to be a general agreement on this point.

Morning Session, Jan. 24.

"Shallow versus deep brood-chambers; narrow spacing and fixed distances," was the topic of a paper by Mr. Noah D. West. "Narrow spacing," he said, "is something less than 1½ inch. We want that spacing that will give us the most brood." His experience was in favor of 1⅜. As to bee-space, $\frac{5}{16}$ has the preference; but he admitted that he had burr-combs, and had to use honey-boards.

"DO WE WANT FIXED DISTANCES?"

"Yes, sir," said he; and he gave me a sly twinkle as he peered over the edge of his paper. Twenty years ago he began using the Quinby-frame hive. He now uses ordinary hanging frames spaced with wire nails driven into the sides; and on some accounts he liked them very much, but they were unhandy for extracting. He exhibited a modification of the Hoffman frame which he preferred. This had straight tob-bars, and the end-bars were enlarged toward the top. As to deep frames, the bees did not breed up soon enough in the spring. He referred to the fact that he was obliged to use a honey-board on account of burr-combs; but he would like to dispense with it, as he observed that bees did not enter the sections as readily as when they were out.

Several intimated, at the close of this paper, that the reason he had burr-combs was because his bee-space was too large. Mr. Scofield said, "Use a top-bar one inch wide, with a bee-space above $\frac{4}{16}$ inch, and you will have no burr-combs." Several others put in that they wanted $\frac{4}{16}$ *scant.*

As to the matter of deep or shallow frames, a considerable number seemed to prefer the Quinby depth, although there were not wanting those who thought they could do just as well with the L. frame, one of them being prominently Mr. Scofield. Mr. Elwood had been around considerably in the spring of the year. His observation was, that bees were doing their best on the deep frame. They would winter just as well on the L., but they would not breed up quite as well as they would on the Quinby depth. Mr. Coggshall said the reason was, deep frames have more honey in them; and this honey is directly over the bees, not off at one end. The more honey *over* the bees the better they will breed.

Mr. Ashmead thought the bees bred equally well in deep and shallow frames, but he preferred the L., for the bees go into sections earlier; and I noticed that several nodded assent to this. As to fixed frames, there did not seem to be very much disagreement on this point. Most of the bee-keepers present seemed to prefer them. Mr. W. L. Coggshall, an extracted-honey man, and one of the largest bee-keepers in the State, however, does not use them and does not want them, neither does Mr. Thos. Pierce. Quite a number testified in favor of the Hoffman frame, and there were not wanting those who preferred the Quinby. But there was one man in the convention, Mr. A. E. Woodward, of Grooms Corners, N. Y., who had used 2000 Hoffman frames, and had now discarded them all for the plain loose hanging L. frame. Quite a number looked over toward me with a comical twinkle in their eyes, as much as to say, "There, young man, how does that strike you?" I asked our friend why he discarded them. One reason was, the bees would propolize in between the uprights. Another reason, the brood did not seem to be built out along where the end-bars began to enlarge toward the top. I then called upon several of the closed-end-frame people, and asked them if they had had any trouble about brood being built out the length of the end-bars. They had experienced no such trouble. Another reason why our friend had discarded them was because he could not alternate the frames. Again I called for the testimony of the closed-end and Hoffmen men. Neither had they experienced this trouble. But for all this, I am very glad to give this testimony right here, because it shows that not every one will be pleased with the Hoffman frame; and I hope that some of the enthusiastic admirers of them—those who have not yet tried them—will be a little slow in giving them too extensive a trial.

I would say right here, by way of parenthesis that I do not want any of our friends to think I do not welcome adverse testimony to some of my "pet ideas," as some might call them. I am exceedingly anxious that both sides shall come out.

Somehow or other this matter of cellar versus outdoor wintering came up. Mr. Ashmead said, that, with an apiary of 100 colonies, he could save, by wintering in the cellar, from 500 to 700 lbs. of stores. I told Mr. Ashmead, that, if he lived in a locality where the winters are rather more open, he would not notice this difference in results. In cold localities there is quite a saving in wintering in the cellar. In warmer localities, say in about the latitude of our own, the difference is not very great; although I have noticed that there is a slightly less consumption, even in Medina, of stores per colony, in the cellar.

A paper from Dr. Tinker was read, on the subject,

"ARE WE READY TO ADOPT A STANDARD FOR THE AMERICAN ITALIAN BEE? IF SO, WHAT ARE THE DESIRABLE CHARACTERISTICS?"

Taking it all in all, the matter was well considered. The doctor alluded to the fact that, up to the present time, the three yellow bands seemed to be the only standard of purity for Italians. But Cyprians and albinos have come in; and for their crosses we need a little different standard. But little has been said of the color of the *hair*. The doctor thought the best strains have white hair. The white hair shows black blood with the bad weeded out. The yellow hair shows that the pure Italian blood has the predominance. He called attention to the fact that, in making exhibits of choice bees, the judges have no standard from which to make their awards of premiums, and he recommended that the association adopt some standard.

W. E. Clark is one of those dry jokers in conventions, and generally makes a pretty good point. He thought it might be all well enough to make a standard for show; but what he wanted was bees for *business*. He had a cat at home that he would not trade for any ten other cats he ever saw. She is a splendid mouser, and kept the premises clear of the rodents; but a very homely cat was she, and neither had she any distinctive markings or fine pencilings. He also had an old speckled hen that he would not trade for any other hen he ever saw. She was a cross between several other strains; but she would beat any well-marked pure-blood in egg-laying that he ever had. He also had some bees that were splendid workers, but they were not very fancy in color. "This standard business," said he, "is just for exhibition. These standard hens and standard cats and standard bees, with just so many shades or markings, do not amount to very much for business."

Mr. Knickerbocker agreed, and further said he had carefully tested these golden-yellow bees. The honey that they gathered had a water-soaked appearance, and he thought they were not as good workers as his leather-colored strains. He emphasized the point that he preferred bees for business.

Mr. Elwood and Mr. Hershiser, however, insisted that it was necessary to adopt a standard for *exhibition* purposes, and that Dr. Tinker's point was well taken. Mr. Elwood said that, if he ordered an Italian bee, and got a hybrid, he would be disappointed. He wanted to get just what he ordered, as to markings, no matter whether the hybrid would be a good deal better bee for business than the regulation three-banded Italians or not. Our judges at honey shows he thought should have some standard whereby they can mark the bees. As it is, there is a good deal of complaint in regard to the way bees are awarded premiums by the judges.

Afternoon, Second Day.

We first listened to a paper by President Elwood. It discussed the poor season, and its causes. A full crop of honey, as a general thing, means a good crop of grain. The fertilization of blossoms by bees is certainly necessary. As to out-apiaries, we should be a little cautious about advising everybody to start them. If a small business does not pay, then a larger one will not. There are some who have a capacity for running a series of apiaries, and there are others who have a capacity for running only one small apiary, and sometimes poorly at that. He lamented the fact of raw sugar having been placed on the free list, and a bounty of two cents a pound being paid on all produced at home. He was not certain just what effect this would have on the honey-trade, but he thought it would work injury. Bakers and confectioners had been using cheap honey, but now they would be likely to use sugar. He thought there was a need of bee-keepers adopting some sort of trade-mark, and that the Honey-producers' Exchange should by all means be continued. The Honey Statistics in GLEANINGS had been sent out free, and had rather conflicted with the operations of the Honey-producers' Exchange, whose bulletins were sent out to members only. As to the Columbian Fair, the bee-keepers of New York should make some arrangement to make an exhibit; but if the managers were to open it on Sunday he recommended that the bee-keepers of York State let it severely alone. I was pleased to notice the general assent to this point, shown in the faces of those present. The discussion of the paper was not brought up at that time, but it was considered later in the form of committees.

Evening Session, Second Day.

The evening session was given over to the commission men, and two papers were read. Both were so valuable and so vital that I am glad to give them entire—not that the other papers in the convention were less valuable, but because the commission men have had but comparatively little to say to the honey-producers. The first paper, by F. B. Thurber himself, was read by a representative of the great firm of Thurber, Whyland & Co., of New York. It is as follows:

THE INFLUENCE OF FREE SUGAR ON THE CONSUMPTION OF HONEY.

After April 1st next, the present duties on foreign sugar, which average 2¼ cents per pound, will no longer be imposed, and a bounty of 2 cents per pound will be given to domestic producers of sugar, which includes the cane sugar of Louisiana, the sorghum and beet sugar of the Western States, and the maple sugar of the East. This will undoubtedly stimulate production in these lines, increase the supply of sugar, and largely decrease the price, although, with low prices, consumption will be larger, and there will be doubtless more or less fluctuations in price, due to this cause.

Just how much lower sugars will be on the 1st of April than they are at the present time, it is impossible to say; but probably not less than 1½ cents a pound, or, say, about 4½ cents a pound for granulated sugar at wholesale.

What influence the cheapness of other sweets will have upon the consumption of honey, is a difficult thing to estimate. Honey is an article distinctive in character, appearance, and flavor. People who are accustomed to using honey want honey and will have it, unless prices should be held at exorbitant figures; but as cheap sugar will undoubtedly stimulate the production and consumption of attractive fruit-preserves in this country, just as it has in England, and the manufacturers of these preserves will undoubtedly continue to advertise and push them, it will have some influence on the consumption of honey.

I would advise a continuance of the same intelligent study of the business that bee-keepers have given it in the past. I know of no line of business that has received more careful or studious attention than your business has during the past few years. Every suggestion made by distributors of your product, tending to make it more attractive and convenient for consumers, has been met, and the little busy bee has been educated to work in a form calculated to extend the consumption of his product.

I have always felt much interest in apiculture; and the Thurber-Whyland Company, of which I am president, will be glad to do all in its power to forward your interests. With regards and best wishes, I remain

Faithfully yours,

New York, Jan. 20, 1891. F. B. THURBER.

The second one was read by Mr. Segelkin himself, and is as follows:

SHIPPING AND GRADING HONEY.

Mr. President and Gentlemen: — I welcome this opportunity with great pleasure, and will describe, as definitely as possible, *what our market demands.* It is certainly to the interest of the producer to put his product on the market in the most attractive and salable style; and we, as the sellers and distributors, are naturally in a position to know exactly the wants of our market. Receiving comb honey in large quantities from all the honey-producing centers throughout the country, we get it in all styles and shapes, and, in many instances, we find there is room for vast improvement and changes. In these days of sharp competition in nearly all the branches of industry, it has been found necessary to put the goods on the market in very attractive style. This is mainly the case with all kinds of food products, such as canned goods, preserves, etc., all of which are handsomely labeled; and those which are put up neatest will find the quickest sale. The consumer will always buy that which looks the most appetizing. As these facts can not be denied on staple goods, it is all the more necessary to use the utmost care in putting up comb honey in the most attractive style, because this is regarded as a luxury—if not altogether, certainly to a very large extent.

We give due credit to a large number of our shippers who are up to the times, and who put their honey up in first-class style. Their goods always find ready sale at the highest market prices. If they do not sell their product outright, they are sure of receiving returns within a short time, and need not fear having their honey carried for months or carried over the entire season. We very often receive comb honey which is put up in bulky, awkward crates, not even glass on the side of the crates, the combs built without separators, so that it is almost impossible to take the combs from the crate without injuring them. Such goods do not compare favorably with first-class ones. They find but slow sale, and prices have to be shaded considerably to move it off. Still, these shippers generally expect highest prices, and are very often dissatisfied and disappointed with the returns, when the fault lies with themselves only.

SINGLE-TIER CRATES RECOMMENDED; MARKING WEIGHTS.

For one-pound sections we recommend a single-tier crate holding 24 or 25 sections. While we are not opposed to the double-tier crate, we believe the single-tier is the more desirable—at any rate, for unglassed honey. If some of the combs in the upper tier start to leak, they will drip over the combs in the bottom tier and soil the whole crate.

We often receive comb honey which is not weighed at all. Others have only the gross weight marked on the crate. Again, others have gross and tare, but *not* the *net* weight; and, again, some is marked in such small and faint figures that the marks are scarcely legible.

We received one lot this season in paper boxes, which we supposed was not weighed, as it did not bear any marks, nor could we find any marks as to the grade of the honey. To determine which was first and second grade white and buckwheat we started to open up the crates. Under the cover we found a slip of paper, stating the quality and weight. What the shipper's reason was for putting the marks under the cover, we are unable to say. No doubt he thought it the right way to do.

Very often the shippers will figure the weight down to ounces, and mark the crate, for instance, "Gross, 28:06; tare, 4:04; net, 24:02." These two ounces we have to throw off every time; in fact, in some cases we are compelled to throw off quarters in order to effect a sale. All this can be and should be avoided by the shipper by simply changing some of the combs, until the crate will weigh an even pound or half-pound; and by doing so he will receive pay for *every ounce of honey.* We would recommend putting *only* the *net* weight in plain figures on the *end* of the crate.

For glassed or unglassed honey we advise the use of heavy paper in the bottom of the crates, turned up about half an inch on the four sides. If some combs should be broken down, this will prevent the honey from leaking through the crate. In addition to this it would be advisable to lay strips of wood about ¼ inch thick on the paper, from side to side, for the combs to rest on. This will prevent the honey which has leaked down from broken combs from soiling the good combs. Of course, it is not necessary to go to this trouble when the honey is shipped in paper boxes.

PAPER BOXES FOR COMB HONEY; FOLDING STYLE NOT RECOMMENDED.

For a paper box we recommend those now used by nearly all the largest producers, who use a paper box called, we believe, the original Scofield box, of which you will find samples on exhibition. It is made of heavy pasteboard, and is strong enough to prevent breakage unless the honey is handled unusually rough. This box is the best ever adopted, and has the preference in our market. We receive honey in many other styles of paper boxes, but none of them take as well. Take the folding box, for instance, which is also largely used, and made of light paper instead of pasteboard. These boxes are not strong enough, and the majority of them will tear by trying to take the combs out of them. You can convince yourselves by samples on exhibition.

Where honey is put up in paper boxes we would advise using a single-tier crate holding 24 sections 5 by 5. The middle section on each side of the crate should be glassed, to show the quality of the honey. Honey put up in this style, clean white crates, and boxes neatly labeled, will always sell at highest prices.

WHAT PROPORTION OF COMB HONEY SHOULD BE GLASSED AND PUT IN PAPER BOXES?

The next important question is, "What part of the honey should be sent to market in paper boxes—glassed or unglassed?" Up to last year we have said, about one-third of each kind, as the demand was about equally divided. We now say, 50 per cent glassed, 30 per cent paper boxes, and 20 per cent unglassed, as nearly as we are able to estimate. During the season of 1889 we had more demand for glassed honey than for unglassed or paper boxes. We thought, that perhaps that year was an exception; but we have had *more* calls for glassed honey this *last* season than the *year before*, and the demand for the same is fast increasing. We could not nearly fill orders this year, and could have sold thousands of crates more. We tried to substitute paper boxes and unglassed honey, but the trade would not have it in place of the glassed honey. We are of the opinion that this demand for glassed honey will be permanent, and we would therefore advise producers to glass more of their honey.

GLASSED HONEY RECOMMENDED.

It is certainly more profitable to glass the honey than to ship it unglassed or in paper boxes. The producer receives the price of honey for every ounce of glass; besides, glassed honey will bring better prices than unglassed, and as good a price as paper boxes. The reason why glassed honey has the preference seems to be that the retailer can take every comb from the crate and make a handsome display of it. This, of course, can also be done with the paper boxes, but the glass will show up every comb. The dust can not settle on the honey, and the glass will prevent curious and inquisitive customers from sticking their fingers in the comb.

KIND OF SECTIONS TO BE USED FOR GLASSED AND UNGLASSED GOODS.

Next comes the kind of section to be used. For unglassed or paper boxes, it does not matter which one is used—nailed, dovetailed, or one-piece section. For glassed honey we should say the nailed or dovetailed section is the most desirable, as the one-piece section does not seem to be strong enough to be glassed. Some producers will fasten the glass to the section with small tin tags; others with small wire nails; and, again, others will glue them. Any one of the methods will answer the purpose, if properly done. If glued, a glue should be used which will stick and hold the glass to the section. We sometimes receive shipments of glassed honey glued; and, as soon as touched, the glass will fall from the combs, and very often hurt the sale of the honey.

PROPER WEIGHT OF SECTIONS.

Another item of great importance is, to have the sections weigh not over one pound each, but less if possible. Our market demands light weights at all times, be the honey glassed, unglassed, or in paper boxes. The two latter generally weigh a little less than a pound, while glassed sections, in many cases, will weigh over a pound, especially if the standard section is used, 4¼x4¼x1¾. We would advise producers to cut down the section in width and adopt a narrower one, say 4¼x4¼x1½ or even 1¼; so, when glassed, the section will not weigh over 14 to 16 ounces. Heavy sections are generally rejected, and we find it slow work in moving them off.

GRADING HONEY.

We would call your special attention to the grading of the honey, which is as important a question as any of the former, and in which not too much care can be taken. Very often we receive honey which is not properly graded, and off grades mixed in with the first grade, and marked, "Not white honey." The outside combs will appear all right; but inside of the crate will be the poorer grade.

We can not take the trouble to open and examine every crate and comb, but have to rely on the shipper, and go by the mark and the appearance of the crate. We sell and ship the honey; and the first thing we know, the party who bought it will complain about the quality, and hold the honey subject to our order. Here we have the alternative, either to have the honey shipped back to us or make an allowance satisfactory to the buyer. This is certainly not very pleasant. It hurts our reputation, and we are apt to lose that customer. Not only this, but the shipper is also dissatisfied, as generally *he* expects the highest market prices, and often will not admit that the honey was not properly graded, while no one but himself is to blame. All this can be avoided if the honey is properly graded.

TWO GRADES OF WHITE HONEY

are sufficient for our market. For a fancy white, select only what *is* fancy white. For a second grade, or fair white, take combs that are stained, or a trifle off in color, and combs scantily filled around the edges. Any combs mixed with dark or buckwheat honey should not be put in with the second-grade white. Such honey can not be sold for white, and will not sell for more than buckwheat; in fact, a straight buckwheat finds readier sale than mixed honey. It should be crated by itself, and marked accordingly.

TWO-POUND SECTIONS.

Our market demands a limited quantity of 2-lb. sections. About 10 per cent of the honey we receive is in 2-lb. sections, which is sufficient to supply the demand. These should be glassed altogether, and put in single-tier crates holding from 12 to 15 combs.

KEGS AND BARRELS INSTEAD OF SQUARE TIN CANS.

For extracted honey, basswood, white clover, or buckwheat, we prefer a keg of about 150 lbs.; half-barrels of about 300 lbs., or even barrels of 500 lbs., whichever can be obtained cheapest. We would not advise the use of 60-lb. square tins as used exclusively in California. Our trade is accustomed to the wooden packages for all kinds of northern, eastern, western, and southern honey, and we see no necessity for a change. The cans are more expensive than kegs or half-barrels; the honey in cans will *not* sell for any higher price, consequently nothing can be gained.

COMB HONEY ALWAYS BY FREIGHT, AND WHY.

I should like to make a few remarks yet regarding the shipping of honey. Comb honey should be shipped by freight altogether. Some of the bee-keepers seem still to think that comb honey must be sent by express only, believing it to carry safer. This is entirely wrong. Honey is carried just as safely, if not more so, by freight—at least this has been our experience. Owing to the short crop last season we received a large number of small shipments by freight, ranging from 10 to 50 crates each, and we had but two or three lots which arrived broken down more or less. In one of these cases the shipper wrote us afterward that the honey had already leaked when he took it to the depot. We reship it in lots of all sizes, often in single crates, and very seldom have a complaint. So far as the responsibility is concerned, all of them—the railroad, steamboat, and express companies—will take comb honey only at owner's risk, and will not listen to any claim if the honey has been broken down while in transit. Why, then, pay the express companies three times the rate of freight lines? We would advise bee-keepers to load the honey in the car themselves, properly protected. If this is done they may feel sure that the honey will arrive at destination in good order, under ordinary circumstances.

Another point we should like to call your attention to; namely, comb honey should be shipped in the original crate only. We received one lot of honey from Central New York this season, where the shipper had gone to work and crated six or eight original crates into *one large* crate. This certainly was too heavy a package to be handled with care, and, no doubt, received rather rough handling. What was the result? We received the honey all broken down, and the shipper was out from 4 to 6 cents a pound—a sad lesson indeed.

BEST TIME TO GET GOOD PRICES.

Last, but not least, when is the right time to ship comb honey to market? We have always advised early shipping—during September and the first part of October. Our experience teaches us that the early shippers obtain best prices, and get quickest returns, be the crop large or short. In all our experience we have never known the market to advance during November and December; but it usually declines as the season passes.

One word for ourselves. We have now been in the honey business six years, and flatter ourselves that we have the confidence and good will of nearly all bee-keepers throughout the country who have intrusted goods to our care. We always endeavor to obtain as good prices for consigned goods as if they were our own, and make prompt returns, and I think there are many here who will bear me out in the assertion. We wish to tender our thanks to our patrons (many of whom I recognize on this floor) for past favors, and respectfully solicit a continuance of your patronage in the future.

HENRY SEGELKEN,
for Hildreth Bros. & Segelken.
New York, Jan., 1891.

A lively discussion followed the reading of these papers, in which both honey-producers and commission men joined. For my own part I was greatly surprised that there was such a demand in the New York markets for glassed sections of honey; and after the discussion Mr. Elwood arose and said we should be very careful about going to extremes. It would not be best for us, as bee-keepers, to glass all our honey next season. It would make a glut in the market. The wisest thing was to glass a certain amount of it, put a certain amount in paper cartons, and a certain amount in 2-lb. sections. What we bee-keepers need to avoid is a glut in the market in any one style of package. As an example, several bee-keepers had, at the advice of Mr. Wright, put their buckwheat honey into ¾-lb. sections—these sections being considerably taller than wide. The result was, they glutted the market with that kind of section; and at this, several bee-keepers nodded assent. A couple of years ago the New York market demanded unglassed sections, and all bee-keepers produced and sent to market that kind. The result was, that the glassed brought a higher price. And, furthermore, Mr. Elwood said that the Western market would not use glassed sections, while the New York market would. A great deal of our honey goes west, and we must be careful to put it up in such shape that a part of it will be salable anywhere.

As to the effect of low prices in sugar, Mr. Segelkin, like Mr. Thurber, did not anticipate that it was going to affect the honey-trade seriously.

Forenoon, Third Day.

BEE-ESCAPES—THEIR USE AND BENEFITS.

An essay that should have been sent in on this subject did not appear; but George H. Ashmead said that his bees were near the highway—too near, indeed, to be pleasant to the passers-by. But lately, by the use of bee-escapes, he could take off every pound of honey without any disturbance whatever. He uses them for both comb and extracted honey.

I was not present at all of the morning session, and hence my note-book has not much regarding it. The afternoon session was brief, and simply took up matters of business.

Although there had been heavy rains, I counted at least a hundred in attendance at one of the sessions. For practical discussion on important themes, I do not know that I ever attended a better convention. Outside of California, the State of New York, I *believe*, has the largest and most extensive bee-keepers in the United States if not in the world; and I tell you it is a great pleasure to take the hand of those who count their colonies by the hundreds, and, I might almost say, by the thousands.

I told the members of the convention that I had a warm spot in my heart for all York State bee-keepers. And now that I have returned home, that spot is a good deal warmer yet. I shall not soon forget my pleasant memories on the bicycle tour, and the renewal of acquaintances at that convention. I am doubly glad now that the North American is to be held in Albany, and that its presiding officer is to be P. H. Elwood. I anticipate that its next meeting is going to be one of the grandest bee-conventions ever held in the United States. The last meeting of the North American was an excellent one; and, unless I am very much deceived by indications, the one yet to take place in Albany will eclipse them all.

SOCIAL CUSTOMS, ETC., IN SINGAPORE.

ANOTHER GLIMPSE FROM BRO. MUNSON, OF CHRIST'S CAUSE IN HEATHEN LANDS.

Dear Mr. Root:—Many days and months have passed since my last letter. I have long waited for time, but time hasn't waited for me; so if I don't "take time by the fetlock" (since I've not taken him by the forelock) I fear that 1890 will die by without a single letter written to you.

This has been a very busy and important year to this mission; and, having all its interests to attend to, I have had to let many a letter go unanswered, many an interesting book unread, and many a pleasant acquaintance uncultivated, for the King's business requires haste.

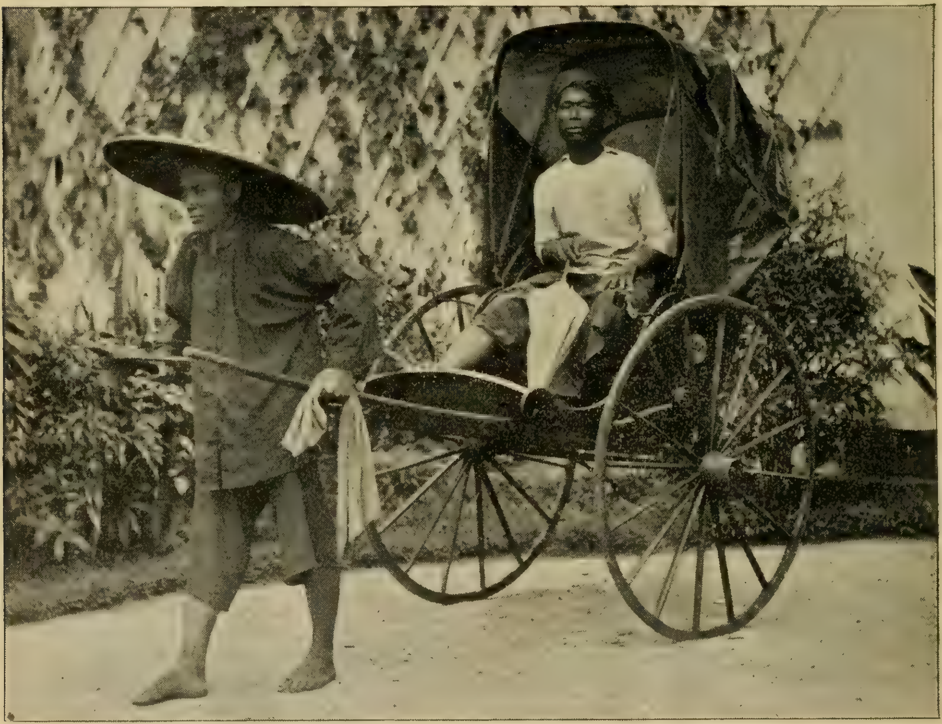
In my last, about the Indian money-lenders, I used an unfortunate expression when I said the Chitty was "*soulless*, or as near it as he could well be." The meaning I intended to convey was, "merciless, pitiless." He has undoubtedly a soul for which Christ died, that is capable of being transformed into the likeness and image of Jesus Christ.

In the picture I send you this time you behold one of the institutions of the East, and just in front of it a sample of one of the institutions of this world—the former a jinricksha, the latter an almond-eyed inhabitant of the land of Sinim, or in, common parlance, a "heathen Chinee." This man is one of the "cooly" class, or a common laborer. Let me first tell you what I know about the jinricksha.

One of the early American residents on the China coast lived in a city (Hong Kong it may have been) where there were no wheeled vehicles of any kind, and no horses or ponies. The only means of locomotion was by foot or in sedan chairs. This Yankee verified the old adage, that necessity is the mother of invention. To carry a sedan-chair, two chairmen were necessary; but when a very light little carriage like the one in the picture had been constructed he found that one man was able to make better speed, with greater comfort and greater economy to the traveler, than two in the old way. The result has been tens of thousands of these tiny road-carts in all the towns from Singapore to Pekin and Tokio; a lucrative employment for thousands of wheelrights and laborers, and a considerable revenue to the government. The chief means of public conveyance here is the hackney carriage and the jinricksha. It costs but five cents to go a mile in one of the latter, and you can ride to your own doorstep at that. They are much more comfortable than the hackney carriages, and four times cheaper.

In Hong Kong and other towns in China, they are beautifully finished, and are used by gentlemen of every rank. Here they are patronized chiefly by the native community and Europeans.

Every vehicle is licensed. A 'ricksha pays one dollar a year, and a hackney carriage one dollar and a half. The municipality registers both the carriage and the driver. You will see a number on the side of the 'ricksha in the picture, and one on the arm of the Chinaman. The man in the 'ricksha is a Malay from the island of Java. His head gear consists of a piece of cloth made expressly for the purpose, and twisted about the head, often leaving the crown entirely exposed. The most singular part of his dress is the garment that supplies the place of pantaloons. It is called sa-rong, and is a piece of figured cotton a yard or more wide, sewed togeher at the ends. This encircles the waist, and, after being folded over, is held in place by means of a belt of some sort. Most Malays wear under this a pair of short close-fitting drawers. They go barefooted, as all the Chinese coolies do, unless they have a small income, when they sport sandals or European shoes.



THE JINRICKSHA, THE COOLY, AND THE MALAY.

By far the most promising race are the Chinese. They are sometimes one thing and sometimes another in religion, but always ancestral worshipers. This is about the only thing you can be quite sure of. The wealthy Chinese have very fine houses, and there are few poor ones that do not live in good ones. They manage to live very well on a little, because so many live together in a single house. As a race they are very energetic and thrifty. It is plain to be seen that they will ere long crowd out the lazier and less hardy races. The Malays and Indians stand no chance, for they can not and do not even try to compete with the Chinese. Ninety-nine hundreths of the government revenue comes from them. They have been well called the Anglo-Saxons of the East. Sir Garnet Wolseley has expressed the opinion recently, in an important article, that, in the future, there will be but three great powers in the world—England, Russia, and China. The Chinese undoubtedly possess the elements that go to make up a great nation; and, when refined and exalted by Christianity, or, rather, by Christ, there will hardly be a limit to their possibilities of greatness.

But I must tell you about our mission to the Chinese. About two years ago Dr. West, from Crawfordsville, Ind., latterly from Iowa, opened a medical mission in the Chinese quarter, and immediately began to treat the sick bodies and sicker souls of the poorer Chinese, the coolies particularly. Almost the first man who came was an opium smoker who wanted medicine to cure his opium habit. The doctor pointed him to the Great Physician as his only hope. He looked, as did the bitten Israelites upon the brazen serpent, and lived. He gave up opium, found Christ, and is to-day walking in the light of the gospel.

Not many weeks ago I baptized several Chinamen, and organized our first Chinese church. It numbers eight, and ten baptized who will, in a few months, be received into full membership.

In our Anglo-Chinese school we have not a few true disciples of Jesus. Some of our brightest and most promising boys are firm believers, and, so far as we can judge, truly converted to God.

There is great joy in this work. It must make the angels' harp-strings ring again as they behold the sight. Native lands and all earthly ties are nothing if they would keep a true missionary from this grand service for our God.

A year ago Dr. West went to China to study the language. So many dialects of Chinese are spoken here along with the Malay, Tamil, and English, that a man must go to the district in China where a particular dialect is spoken in order to learn it in its purity. When the doctor returns in March, and gets well settled down to his work, we expect great things. There are 100,000 Chinamen here, and surely the Lord has some hundreds of people among them who will be gathered out very soon, we hope, and united into Christian churches. Pray for us.

R. W. Munson.

Singapore, S. S., Malaysia, Nov. 30, 1890.

[Friend M., you can not tell how interesting the picture you send us is to me. But I must confess that, were it not for the places occupied, I do not think I should be able to tell by the dress which is the rich man and which is the poor one. When you spoke about carrying passengers for five cents a mile, it occurred to me that we might possibly bring the jinrickshas into our own country, thus furnishing employment for some of those who beg so hard for something to do. But I am afraid that our American people would make a protest. It is true, we have poor men, and we have millionaires; but for all that, it would be hard to find men in America who would submit to the position of the coolies. A man might peddle milk, possibly, with a cart, and not mind it; but he would not draw his rich neighbor; neither would the rich neighbor submit to be drawn by his poorer neighbor, and I thank God for it. I am looking for and praying for the time when there shall be still more neighborly feelings between the rich and the poor; and I am praying with a pretty bright faith too. The answer is to come just where you are looking for answers to your troubles, dear brother—through Christ Jesus.]

WOULD THE TRUTH INJURE THE FOUNDATION TRADE?

FRIEND HASTY EXPLAINS HIS POSITION.

I see that, on page 94, friend Rice desires that I should explain. The state of the case is, that I have no quarrel with foundation in the hands of those who use it and know why. My combat is with the musty old untruth, that a pound of wax costs the bees twenty pounds of honey to make it. This misstatement makes a multitude of beginners in our art think they must use foundation, whether they can see any profit in its use or not. Many of these beginners are in localities where apiculture can not be pursued with profit, except in the most economical ways. Foundation costs money, and very fair brood-combs can be secured with only the expense of a little time and care. Moreover, in many lean locations, my own included, it is plain that full sheets of foundation in the sections very seldom pay for themselves. Where the bee-keeper can see plainly that they do pay for themselves, let him use them; but let there be no assuming that it *must be so*, on account of a big story about wax secretion. Let there be no hiding of our faces from the facts. I rejoice to see that Langstroth's work, as at present edited, comes down "several cats" from the old wild statement. In the last edition, bees are credited with being able to make a pound of wax from seven pounds of honey. I am pretty well convinced that there is room to come down considerably more; but I can be thankful for the concessions we already have. Both brood-combs and super combs for extracting, in the hands of careful keepers, are permanent fixtures, or nearly so; and thus the trade demand for heavy foundation is quite largely to supply the wants of beginners. As for those careless folks who let their combs be eaten up, and then buy sheets of foundation to replace them, I guess they are *always* beginners—beginners who seldom know whether the material they buy pays for itself or not. I did not mean that a bee-keeper in a good location in Southwestern Wisconsin would necessarily use less foundation if he knew the facts. I meant that the total amount used, the country over, would be much less if the stimulant to its use, which an absurd statement furnishes, were withdrawn. You see, I am very free to retract what I didn't say; but as to this last assertion, I think I shall be hit by a good many stale cabbages and turnips first before I take it back.

Richards, O., Feb. 3. E. E. Hasty.

[It now becomes *our* duty to make a little apology. Over a month ago, friend Hasty sent us the short tem which appears below; but instead of going into the journal promptly, it got laid away somewhere and was not used.]

FRIEND HASTY MAKES THE "AMENDE HONORABLE."

Friend Root:—It seems to be a proper time for me to eat a little "humble pie." I do not

think that Gleanings (or either of the other leading journals) would suppress evidence on the honey-wax question, or wantonly falsify to bolster the foundation trade. If my article which is complained of amounted to such a charge, I retract it to that extent. I think, however, that a public journal can do more mischief by keeping silence and letting a profitable error have full swing, when it has gained that advantage once, than it can by the grosser forms of ill doing. But, hold on! if I keep on saying what I think, this will be another kettle of hasty-pudding, and not a humble pie at all.
E. E. Hasty.
Richards, O., Jan. 5.

All right, friend H. There will not be any trouble with the "pudding" so long as you talk or write in the above spirit. And, by the way, the best remedy I have ever known for uncharitableness is a good bee-keepers' convention. Those who were present at the recent Detroit convention will, I am sure, bear me out in this; for each and every one felt as if we were under bonds not to judge hastily nor uncharitably of any absent brethren, especially if such have been unfortunate.

OUR QUESTION-BOX,

With Replies from our best Authorities on Bees.

Question 178. *Is it a good plan to fasten bees in their hives by means of wire cloth, while in the cellar?*

No.
Illinois. N. C. J. A. Green.

I think not. R. Wilkin.
California. S.

I don't think it a safe plan.
Ohio. N. W. H. R. Boardman.

No. It is worse than useless.
Ohio. N. W. A. B. Mason.

No, sir. It is done at great risk.
New York. C. P. H. Elwood.

No, and there is no need of it in a dark cellar.
Vermont. N. W. A. E. Manum.

No, never, according to the opinion of Doolittle.
New York. C. G. M. Doolittle.

It is not necessary unless you have too much light in your cellar. P. L. Viallon.
Louisiana. E. C.

No. The old must die, and it is their nature to leave the hive when the end draws near.
Illinois. N. W. C. Mrs. L. Harrison.

No, not if they find it out. If you can fasten them in, and not let them find it out, it may work all right.
Wisconsin. S. W. S. I. Freeborn.

It is not, unless the fastening is in the shape of a cage of, say, two quarts' capacity. Close confinement with wire cloth causes uneasiness.
New York. E. Rambler.

I do not know. Under some conditions I think it might be, although I never practiced it.
Michigan. S. W. James Heddon.

Now, that's one of the things I think I know. It's *not* a good plan. I'd a good deal rather have them on the cellar bottom than on the bottom-board.
Illinois. N. C. C. Miller.

I should say no. When bees find that they are prisoners they want to get out, and will worry and work to do so. Bees should be quiet, to do well.
Wisconsin. S. W. E. France.

I do not like to do this. If the cellar gets a little warmed up, the bees become active; and if shut in they will be much injured if not destroyed.
Michigan. C. A. J. Cook.

No, emphatically. Keep them in the dark; but if any bees become so restless that they will not stay in the hive it would only cause them to disturb the others if they were shut in.
Illinois. N. W. Dadant & Son.

Bees should never be fastened in their hives by wire cloth or other means, excepting on a journey. The knowledge of their captivity creates a great alarm among bees, and is a dangerous experiment at any time of year.
Ohio. S. W. C. F. Muth.

I should say both yes and no. Sometimes, yes; usually, no. If you choose to cover the whole front of the hive with a big wire-cloth ante-room, in which uneasy bees can come out and promenade, I think there would seldom be any ill results.
Ohio. N. W. E. E. Hasty.

[I admit, friends, that it looks a little "cheeky" in me to disagree with such a respectable body of men when they say "no, no," with such emphasis. I think a good many of you, however, say no, because you have got that idea in your heads without having ever tried it very much. In moving bees, or in shipping them, we always shut them in a hive by means of a wire cloth, and sometimes they are weeks shut up in this way, without very much detriment; and it is certainly much worse to confine bees to their hives when they are bundled off in *warm* weather than it would be to thus confine them in a *cool, quiet cellar*. While I would not advise the average beginner to fasten his bees in the hives with wire cloth, I want to tell you that I wintered fifty or sixty colonies very successfully, and had them all fastened in their hives. The cover was removed, however, and the whole top of the hive covered with wire cloth. They were in a sawdust-packed bee-house. Part of them, instead of having wire cloth over the whole *top*, had it over the whole *bottom*. It was low enough down so the dead bees could be a couple of inches below the combs. In some of them there were no dead bees of any account on the wire cloth when they were set out toward the last of March. I do not know of any reason why my experience should have been so much different from that of others, unless it was at a period when I kept most of my stocks rather weak in numbers. A nucleus would get along much better when fastened in a hive than will a rousing colony. I rather think I hadn't a real good rousing colony in the whole lot.]

TOBACCO COLUMN.

CONDITIONS UNDER WHICH WE GIVE SMOKERS TO PERSONS WHO STOP USING TOBACCO.

First, the candidate must be one of those who have given up tobacco in consequence of what he has seen and read in this department. Second, he promises to pay for the smoker should he ever resume the use of tobacco in any form, after receiving the smoker. Third, he must be a subscriber to GLEANINGS. Any subscriber may, however, have smokers sent to neighbors or personal acquaintances whom he has labored with on the matter of tobacco-using, providing he give us his pledge that, if the one who receives the smoker ever uses tobacco again, he (the subscriber) will pay for the smoker. The one who receives the smoker in this case need not be a subscriber to GLEANINGS, though we greatly prefer that he be one, because we think he would be strengthened by reading the testimonials from time to time in regard to this matter. The full name and address of every one who makes the promise must be furnished for publication.

NEVER TO USE TOBACCO AGAIN.

I have concluded not to use tobacco in any way or form for life; and as you offer a smoker, I should like one; and if I ever use tobacco again I will pay you the price of the smoker.

Mt. Horeb, Wis., July 30, 1890. M. T. LOWE.

KEPT FROM IT FOR 6 MONTHS TO START WITH.

I have quit smoking tobacco for six months. Will you please send me a smoker? If I smoke again I will pay you for the smoker.

T. C. BROWN.

Burnside, Mich., Nov. 19, 1890.

A BOY OF 15 BREAKS OFF.

I have been using tobacco, but have concluded to quit. Please send me a smoker, and if I ever use it again I will pay you for the smoker. I am 15 years old, and have 5 nice stands of bees. FRED BUNDY.

Birdseye, Ind., Aug. 21, 1890.

COULDN'T BREAK THE FETTERS.

Find inclosed 75 cents in stamps to pay for the smoker you sent me. I have commenced using tobacco again, and, according to agreement, must pay for the smoker you sent me.

ELMER E. SHARP.

South Greece, N. Y., Sept. 26, 1890.

FOR TWO YEARS A FREE MAN.

I have received GLEANINGS for about two years, and through the influence of the Tobacco Column I have made up my mind to quit chewing the filthy weed. You can send me a smoker; and if I should break my pledge I will pay for the smoker. N. A. KREMER.

Canaan, Ind., July 29.

A YOUNG CHRISTIAN'S CONCLUSION.

I am now 21 years old, and have been in the habit of using tobacco some, but am trying to be a Christian. I have concluded to do without it, and that I can put my money to better use, and feel better over it. Please send me the smoker; and if I should use tobacco any more I will pay you for the smoker.

PETER W. SMITH.

Ephratah, N. Y., Sept., 1890.

A WIFE GOES SECURITY FOR HER HUSBAND.

My husband has been an inveterate smoker for many years, but for some time he has resolved to discontinue its use. These good resolutions have as often been broken. The last three months he has been reading the Tobacco Column, and I think his resolutions have been greatly strengthened thereby, as he has not touched the vile weed in that time. Please send me a smoker; and if he should again break over I will pay you for it.

JENNIE CHERRINGTON.

Pine Grove, Ohio, Sept. 9, 1890.

STILL "HOLDING THE FORT."

Through the influence of the Tobacco Column I made up my mind some 18 months ago to quit the use of tobacco. I have used it the greater part of my life. You can please send me a smoker; and if I should ever chew or smoke again I will pay you for the smoker. It has been 18 months since I have used tobacco in any shape. W. S. FESSENDEN.

Mountain Home, Texas, June 29, 1890.

A DOUBLE PLEDGE.

I see that you give a smoker to any one that quits the weed. Please send me one. If I ever commence the use of the weed again I will pay you $1.00 for the smoker. Will Lane is a friend of mine, and he has quit using tobacco also. I pledge myself to pay for them if we ever commence the weed, and will pay you $2.00 for them. JOHN J. ELLIOT.

Holden, Mo., Sept. 18, 1890.

"BRINGING IN THE SHEAVES."

Friend Root:—I always speak a word in regard to tobacco and temperance, and I got a new convert to the cause, friend August Roesler, an energetic man, who has for ever laid aside the filthy weed. If you will send him a smoker I will see that he gets it, and will also watch him close; but he says he will pay for the smoker if he uses the weed again. But no danger; he is settled. STEPHEN ROESE.

Maiden Rock, Wis., Sept. 30, 1890.

OUT OF BONDAGE FOR 21 MONTHS.

I have been a reader of GLEANINGS for a long time, and have admired your manly, earnest, and liberal efforts to induce people to quit the filthy use of tobacco. I think it is due your influence, at least in part, that I have been able to leave off the quid. If you see fit to send me a smoker, I shall endeavor to keep it as a testimony against the filthy habit. I have not tasted tobacco for 21 months, and hope, by divine favor, never to use it again, unless as a doctor prescribes; but should I, in weakness, take to it again, I here agree to pay you full value for the smoker. S. L. GREER.

Disco, Tenn., Dec., 1890.

OUR HOMES.

And as Moses lifted up the serpent, even so must the Son of man be lifted up; that whosoever believeth in him should not perish, but have eternal life.—JOHN 3: 14, 15.

Toward the close of the article from Bro. Munson, in another column, he mentions a poor opium smoker who came to the missionary doctor for something to cure his opium habit. I wonder whether there are any among the readers of GLEANINGS who have had experience in fighting this terrible thing. Physicians tell us that, when one has once become a slave to opium, the tobacco habit and even whisky habit are as nothing compared to it. A good many of them say that the opium eater or opium smoker can not be cured unless his friends take him in hand and keep him from it by main force. Opium so paralyzes the will power that the victim is, in one sense, powerless. A friend of mine who was given opium by his physician has told me something of the terrible struggle. And, by the way, this physician administered it without the patient or his friends knowing what it was that he gave. Is it wise or is it right to take medicine of any sort without knowing what you are doing? Our physicians are bound by the laws of the land to tell honestly and truthfully to the best of their knowledge what it is they are giving their patients; and I for one believe that a good many valuable lives would be saved if the number were larger who absolutely refuse to take *opium* under any circumstances. Do as a neighbor of mine did when the doctor told him he would die if he did not take whisky. "All right," said he; "then I will die; but I am going to die a sober man." Did he die? Not a bit of it. A man who has grit enough to tell his physician, "All right, then I will die," generally gets well. And I think instances are quite plentiful in most neighborhoods where people die because of the *medicines* and not because of the disease. Our most intelligent and soundest-thinking people are coming strongly to this conclusion. Our good friend Prof. Cook leads us, as you may remember. The last time I met him he told me to go on preaching and teaching to let medicine alone. He said I could not very well overdo the matter just now.

Well, now, about this opium habit. The missionary doctor told the poor heathen, crippled and stupefied as he was by the opium habit, that no man in the wide world could cure him. All the doctors and all the remedies known to the present age are helpless. They can fuss and experiment some with the patient, no doubt; they can, may be, substitute one stimulant for another: but the satanic demand is not satisfied. The inexorable craving will swiftly drag the patient down to a grave that is much the same as the grave of the drunkard. This missionary doctor, mind you, had other remedies besides those known to the *materia medica*. When the patient needed spiritual help he was ready to give it in place of medicine. "He pointed him to the Great Physician as his only hope." Perhaps he did it with little faith. The poor heathen Chinee, however, had faith, even if the doctor had not. He followed directions as best he knew how.

> And as Moses lifted up the serpent in the wilderness, even so must the Son of man be lifted up: that whosoever believeth in him should not perish, but have eternal life.—JOHN 3: 14, 15.

He looked to the Lamb of God who taketh away the sin of the world, and was healed. Was he then able to give up opium? Why, to be sure he was. The Great Physician does not make any half-way work about it; and our poor besottted heathen brother that was, is today walking in the light of the gospel. Is it any thing strange or wonderful? Not at all. Evidences of such wonderful healing are lying all round about us. Those who are only partly healed, or have afterward gone back, have surely forgotten or neglected to look constantly up to the Great Physician. The figure of Moses lifting up the serpent in the wilderness is perhaps the plainest that can be placed before us. It shows us by a picture, or by an object-lesson, how exceedingly plain and simple is the remedy for *all* sin. Of course, we must look in faith believing — there must be no half-way work about it; and we must keep our eyes constantly on Christ Jesus.

A good deal is said nowadays about tobacco substitutes. I should be very glad indeed to know that there is a substitute that is not just as bad as the tobacco itself. But, bless you, friends, he who is looking to Christ Jesus needs no tobacco substitute nor substitute of any kind. Besides, when we come to Jesus to be cleansed from all sin, the Great Physician does in reality cleanse us from *all* sin. A man with evil and vicious propensities is not very much better off when he gives up tobacco—that is, if he holds on to those evil propensities and passions just the same. We need to be cleansed from *all* sin. The use of stimulants is only a small part of what goes to make up a sinful heart: and if we lay all the blame to stimulants or intemperance we are making a mistake. Although, as a rule, we find the inmates of our penitentiaries and jails using tobacco and liquors (when they can get them), there are quite a few of these who practice *total abstinence* so far as stimulants are concerned.

A few days ago I was talking with a friend who is fighting against the tobacco appetite. He said, "I would give a hundred dollars this minute if I were clear of it." A bystander said, "Oh! I would give more money than that." I assured them that the terrible fight against the old habit would not last always, and that it would by degrees grow less and less. I told them that these *fierce* temptations occur only occasionally, and that very soon they would discover that, a great part of the time, it would not torment them at all. The first speaker then mentioned a man by name—a mutual friend of all present—who tried for two years to shake off this habit, and he said he wanted tobacco just as bad the last day as he did the first.

"Mr. Root, it is asking a man to shoulder a pretty big task, if this thing has got to continue right straight along for two years without respite."

Very likely he did not use exactly the above words, but it amounted to that, as nearly as I can remember. As our friend is a Christian—a member of the church—I exhorted him to bear it for *Christ's* sake. Said I:

"Look here, my friends; there are boys all around you. They are influenced more or less by you. You are expert mechanics, each in his own line. These boys have good reason to look up to you with admiration and respect for your separate abilities; and they will also, *in spite of all you can do*, be inclined more or less to do as you do in regard to this matter of using tobacco. When you think of them, and think that it is something that will follow them through life, can you not for *their sakes*, or, as I said before, for *Christ's sake*, undertake to bear this burden? When it becomes too heavy for you to carry, go down on bended knee and ask help of Him who said, 'Come unto me, all ye that labor and are heavy laden.' "

Then I tried to tell them that Christ Jesus bore far heavier burdens than any of us are called upon to bear. For our sakes he said, "Nevertheless, not my will, but thine, be done." And as the Father did not see fit to let the cup pass from him, he bowed his head in meekness and submission. He extended his arms, and meekly bore the anguish and torture of being nailed to the cross. The first speaker remarked right here, "Mr. Root, that is something I never could understand nor comprehend. I can not see why God should demand of his only Son that he should undergo this awful torture for *anybody's* sake."

Now, my friends, I want to tell you that, in attempting to answer this, I unconsciously brought new light into my own soul; and I want to confess to you to-day that, through all my life while I was a skeptic, and since I have become a Christian, there has been something dreadful to me in regard to this spectacle of the cross. It has seemed as if some mistake had been made in bringing such a horrible spectacle into the Holy Scriptures. It has seemed to me like a relic of heathen savagery. Can human imagination picture any thing more revolting to sensitive and tender feelings than the spectacle of driving great nails through living flesh and blood, and of such a scene of slow and horrible torture? God is *love*, so the Bible tells us. What good can come by holding up before our gaze constantly and frequently this picture of a meek, innocent, inoffensive character like that of Christ Jesus, going meekly and humbly to an ordeal like this? My friends, mind you, had just been telling of the crosses *they* had to bear. One of them said, that, if he gave up tobacco, he could not sleep nights—he would be unfit for business; but notwithstanding, I urged that it was the thing for him to do. All at once it burst upon me that God had chosen, for good and wise reasons, to hold up before a sinful and struggling world a picture of the *hardest* trial and most *severe* ordeal that any human being could think of. In short, this whole thing was arranged with the express idea that no poor struggling soul should *ever* say, "My burden is greater than *even the Son of God* was called upon to bear." Men are often called upon to meet sudden death, and, in some cases, a death of torture; but I can not remember that civilization or Christianity ever demanded that one should take up *voluntarily* a slow, lingering torture, such as that of the cross. We are told by history that the victims frequently lived, unless sooner killed with clubs, for several days in a kind of anguish and torture which we sincerely hope are unknown at the present time. Our Savior suffered about six hours; and while he suffered the bodily pain, he suffered in angish of soul in seeing the whole world, comparatively speaking, choosing wickedness, sin, falsehood, injustice, corruption, and crime. In this present state of affairs he could realize that nothing but his death and the shedding of his blood would answer. He died, that humanity might evermore look up to him as a model, not only in life, but as a model in death—a sacrifice for us. He died, that we might live. Now, then, my friend, when your burden seems heavy—when you are tempted to think you can not stand it any longer, or when you feel like saying, "I *won't* stand it any longer," remember the example of the Master. It was as hard for him as it is hard for us. He shuddered and shrank at the very thought of it. He looked in vain for some outlet—for some other way—just as you and I have been doing. He prayed even for God to spare him; yes, we are told until the sweat like great drops of blood stood upon his forehead. But when God decided that the sacrifice and the atonement *must* be made, he bowed his head in submission. *We*, as a rule, suffer because of our *sins:* Jesus was without sin. The thief on the cross hit it exactly when he said, "We receive the due reward of our deeds; but this man hath done nothing amiss." A young friend told me, not long ago, that his struggle against a certain kind of temptation was just about all he could stand. I knew of his former trials and difficulties; and I noticed, too, that for some time back he had apparently risen above them all. His record has been for some time almost faultless. He attends our meeting, testifies for Christ, and presents a cheerful and pleasant face to all his friends. He is apparently "holding the fort nobly;" yet when I came to get a glimpse behind this fair exterior he said something like this:

"Mr. Root, if this thing does not soon let up, it seems as if the strings would break."

Do you ever feel so, dear reader? Don't be lacking in faith. The *strings* will not break. An all-wise Father has given his promise to the contrary (see text in our previous Home paper). "There hath no temptation taken you but such as is common to man."

Be not weary, dear friend, in fighting life's battles, and in fighting hard for the cause of Christ Jesus, even though you have suffered long and have been kind, without any special blessing coming from it. Be steady, and hold on; the reward will come soon. Ye shall reap if ye faint not. Remember the words in Revelation—"These are they which came up out of great tribulation, and have washed their robes, and made them white in the blood of the Lamb." Your old friend A. I. Root has had some experience in this line; and I tell you there are no truer words in the Holy Scriptures than these: "Eye hath not seen, nor ear heard, neither hath entered into the heart of man the things which God hath prepared for those that love him." It is the overcoming that does the business. "To him that overcometh will I grant to sit with me in my throne." I had been unconsciously holding up to these friends of mine the cross; and I want to tell you of the reward that came to me for my poor feeble exhortation right in that line. I too, as you may know, have been fighting against temptations. It has seemed many times to me as if, as my young friend expressed it, the "strings" would break. But I held on and kept on praying. Now and then deliverance would come, as I have told you. But when I had climbed over one temptation, another was sure to come. Well, the greatest deliverance I have ever known in my life came after that talking about the cross. The temptations that I had been battling with so long and so fiercely on that morning seemed to fall away and go away off in the dim distance. In trying to describe it, these words came to mind: "So far as the east is from the west, so far hath he removed our transgressions from us." I have told you how I have for years avoided temptation as the intemperate man did in going home by a longer route so as not to take the street where the saloons were. It just occurred to me that day, that I need not take the longer route any more. I met old temptations face to face, without a waver. It has all my life been hard for me to take people to task, even when it is my duty to do so. Yes, I usually dread for hours, sometimes, to talk with even the boys when they need talking to. I have many times prayed that God would help me to overcome this diffidence in doing duty. I have wished and prayed that I might be able to reprove, without a shaking tremor in my voice, and an embarrassment that made it seem as if I were the guilty one; but God had not seen fit to answer the prayer, and so I had come to regard it as a thorn in the flesh. Once in defending myself a man said to me something like this:

"If you are honest and sincere, what makes your voice tremble so, and why do you get so excited? Why don't you talk coolly and quietly as I do?"

I replied, "My voice trembles because I *am* excited and stirred up. I wish I *could* talk coolly and quietly at times like this. God has not seen fit, as yet, to give me coolness and calmness, therefore I am doing the best I can."

Well, since I have got my mental vision fixed on a crucified Savior, it has seemed as if that prayer of these long years has been suddenly answered. I have been through our whole establishment, and talked with our boys about the tobacco habit as coolly as I would talk with my wife about it. I have met with provoking things, and have passed through many trying places; but I have not once since that time spoken a word hastily or that I would recall. I have read over the words of our text, perhaps hundreds of times, yet it never was plain to me until just now that it is *our* privilege to look and be healed, just as it was when Moses lifted up the serpent in the wilderness. Instead of looking at the brazen serpent, however, it is our privilege now, since Christ has come and suffered, to turn our eyes toward the figure of the cross. And there is no mistake in the words of the last of our text: "Whosoever believeth in him shall *not* perish, but have *everlasting life*."

EDITORIAL.

Let us run with patience the race that is set before us, looking unto Jesus the author and finisher of our faith; who for the joy that was set before him endured the cross, despising the shame, and is set down at the right hand of the throne of God —HEB. 12: 1, 2.

WE see by the papers that Dr. A. B. Mason has been appointed postmaster for Auburndale, Ohio.

A NEW DESIGN.

OUR engravers have just finished a new design for the title page of our journal. Turn over the leaves and see how it sets off Stray Straws.

IMPLEMENTS FOR BEE-KEEPING.

PRACTICAL bee-keeping is resolving itself into fewer and fewer implements. The price at which honey sells will not warrant us in purchasing a lot of paraphernalia not absolutely necessary for honey-production.

GLASSED SECTIONS.

THE above seem to have taken the first place in the markets of New York city. A few years ago we supposed, in fact truly, that glassed sections had gone out of market everywhere; but now they are starting up again in the East.

THE AMERICAN BEE-KEEPER.

THE second number comes out, like the first, with the vigor of age. On page 30 there is an illustrative article describing the Rhode Island Nellis hive. This uses the Hoffman frame, section-holders, etc. It appears to be a first-class hive.

STRAY STRAWS.

IT seems to please, as it is being copied in other periodicals. By the way, we might as well acknowledge the corn. We first saw the scheme in the *Apiculturist* and in the *Bee-Hive*. It is a good department, but you want a good man to manage it.

FIVE NEW BEE-PERIODICALS.

THE editor of the *American Bee Journal* says, "Five new bee-periodicals have been launched upon the sea of bee literature since Jan. 1. It must have taken considerable enthusiasm in the publishers to do this, after the failure of the honey crop the last season."

FOUR-PIECE AND NAILED SECTIONS IN YORK STATE.

FOUR-PIECE and nailed sections seem to be used considerably among the bee-keepers of New York and Vermont. The former are generally glued; and many of the bee-keepers whom we visited had some sort of gluing-machine whereby the putting-together and gluing could be accomplished expeditiously and neatly.

THE BEE-KEEPERS' UNION.

WE learn from the *American Bee Journal*, by the returns up to Jan. 31, that the following officers were elected:

General Manager, T. G. Newman.

President, James Heddon.

Vice-presidents, Prof. A. J. Cook, G. M. Doolittle, A. I. Root, Dr. C. C. Miller, G. W. Demaree.

We are glad that the officers were re-elected, especially the General Manager.

UNGLASSED SHIPPING-CASES.

OCCASIONALLY somebody will send us honey in shipping-cases without glass. The fragile nature of the contents can not be seen by the freight-handlers, and the result is that it usually does not arrive in good condition. Again, it does not show off in the markets. If bee-keepers could only see it, it is money in their pockets to glass their shipping-cases. A lot of unglassed cases we have been fixing over. We bored three 2½-inch holes directly in front of each row of sections, and tacked a piece of glass inside so as to cover the three holes. The honey in being sorted over was put back in said cases, and the appearance is decidedly improved.

WHAT DOOLITTLE THINKS OF GLEANINGS.

THE following is a kind word from G. M. Doolittle:

> I am glad to see the subscription list of GLEANINGS gradually increasing year by year; and it is nothing but what I expected, for you are making GLEANINGS so valuable that no one can afford to do without it.
>
> Borodino, N. Y., Jan. 30. G. M. DOOLITTLE.

That our efforts are appreciated, is attested by many letters like the above from some of the best and most successful bee-keepers. Such testimony is valued.

ENLARGEMENT OF THE EDITORIAL DEPARTMENT.

SOME of our subscribers have doubtless noticed that we have increased this department from three to four times its former size, and we find it is beginning to be appreciated already. E. L. Pratt says: "I hope you will continue your *good* editorial department to the same extent as in the Jan. 15th issue." Thanks, friend P. It is a great deal of work, but we will endeavor to keep it up. While on the train, going to a bee-convention, we said to Dr. Mason once, "What department do you like best in a bee-journal?" "I always go for the editorials," said he. By a little inquiry we found that others do likewise. We will endeavor to give the latest and best information from all sources.

WHO IS TO BLAME—THE COMMISSION MERCHANT OR THE PRODUCER?

A FEW days ago we received a consignment of several thousand pounds of comb honey. The shipper called it first quality. When it arrived we found that the combs had not been sorted, and the sections had not been scraped; in fact, the eggs and remnants of moth worm were present on a number of the combs. The honey had been stored without separators. It was bulged in a good many instances beyond the sides of the section. If bee-keepers send out honey of this kind, and call it first quality, and then complain to the commission men about low returns, who is to blame? Not the commission man.

STAPLES AND THE BLUEBERRY SWINDLE.

FROM a private letter we extract the following:

> L. D. Staples was convicted on the second and third counts of indictment; viz., for dewberry and blueberry scheme, and the fraudulent-advertising scheme. Sentence yesterday, 14 months at Detroit House of Correction. J. MCQUEWAN, Clerk.
>
> Grand Rapids, Mich., Jan. 28.

Truly, the way of the transgressor *is* hard; but we may rejoice to know that the laws of our land do reach such as he. For years he has been shown up through the agricultural papers since we first exposed him in GLEANINGS; but by some means he has managed to find new fields for his work, and new victims for his swindles. He is, however, now stopped, for some little time at least.

YELLOW CARNIOLANS.

IN response to our editorial in our issue for Jan. 15, E. L. Pratt writes: "You ask how to tell yellow Carniolans from Italians. By their disposition and color. Do the Cyprians look much like Italians?" Yes, Bro. Pratt, Cyprians do look a good deal like the bees from Italy; and we have found, usually, that it is only those who are expert in such matters that are able to tell the difference. We have no difficulty here at the Home of the Honey-bees, nor has any one who has closely observed the matter. But the average customer does not. Now, while you are about it, can't you make the abdomens of your Carniolans *all* yellow—that is, without any yellow bands?

WHO MADE THAT PHOTOGRAPH OF THE SOUTHWEST WISCONSIN BEE-KEEPERS' ASSOCIATION?

The beautiful photograph which we reproduced on page 886, last year, and which has been admired so much, and has since been copied in two other papers, did not bear the name of the photographer, otherwise we should have been glad to give the name in the first place. The photograph was an unusually fine one, and for a group almost remarkable. We have since learned it was executed by Mr. and Mrs. Geo. H. Perry, Platteville, Wis. They will doubtless be glad to furnish other copies.

DISCARDING THINGS PREMATURELY.

We often hear it urged, as an objection against a device, that it was invented, used, and discarded, long ago. In spite of this fact, in some instances the discarded invention seems bound to assert its merits, and up it bobs, as serenely as it did at first. The second time, we begin to see the point; and bee-keepers west, east, north, and south, become enthusiastic in its praise. An example of this is fixed distances in frames. We can not conclude, therefore, that, because a thing was once used and discarded, it is therefore valueless after all. The lesson that comes to us here is, we should be careful about discarding things prematurely. It is almost as bad to do this as it is never to accept or recognize a new thing of merit.

ADDING INSULT TO INJURY.

Of late, quite a few have been reported who purchased honey, and then made an excuse for not paying for it by claiming that it was adulterated. We have one or two such customers ourselves, and three or four more have been reported. It is bad enough to raise honey and not get any pay for it; but when it comes to accusing the honest bee-keeper of being a *swindler* besides, it seems to us that forbearance ceases to be a virtue; and we hereby give warning that we shall give name and full address of every such person who introduces this sort of excuse, or tries to come this game upon us. It is true, there may be adulterated honey found in our land; but you don't buy it of *bee-keepers* and *honey-raisers*. Before any man's name is thus put in print, this slip will be sent him; and if he has any defense to make, we will give him ample time to do so.

NEW ADVERTISING RATES.

We have prepared a new schedule of advertising rates. While in some cases it is stiffer and in some a little more liberal than the old rates, its application is much simpler, and almost anybody can tell with very little figuring what his advertisement will cost. See rates on first page, inside of cover. This, of course, in no way alters existing contracts for advertising for the current year; but all *new* contracts and new estimates will be made from the new schedule. We also give, for the convenience of the few, what are called "space rates;" that is, you can buy so many lines and use them up in large or small advertisements, just as you choose, in every number, in every other number, or in every three or four numbers. Send for our "Hints to Advertisers," mailed free on application. It tells when and how to advertise apiarian supplies, nuclei, bees, queens, etc., how to write an advertisement, and also how to make a little money go as far as possible.

PROSPECTS FOR NEXT SEASON.

If the number of bee-keepers' catalogues of bee-supplies which we are printing (to say nothing of those done at other houses, noticed elsewhere), and if the large amount of hive and section making machinery we are sending out means any thing, it means there is going to be an extra good season next year. We have never before had such a run for machinery. Our machine-shop is having a big rush; and it is somewhat behind in consequence. This does not necessarily signify that competition is going to be any stronger on account of new supply-dealers or the increased facilities of old ones, but that the bee-keeping industry is growing and spreading, the world over. We wish all every measure of success. We have a *big* country, or, if you please, a big world, and there is *plenty* of room for all, even for the bee-journals, though the rule of the survival of the fittest will rather crowd some of them before the year is up, we fear. Competition! so much the merrier. We shall get better supplies and better journals; in fact, they begin to sparkle already in their new dresses and innovations.

WINTER WEATHER IN ENGLAND AND SPAIN.

We notice by the *British Bee Journal* that they are having unusually severe weather. They have had it as low as 27 degrees below the freezing-point, or, as we would term it in this country, five above zero. In the south and southeast of England they have had sixty days of frost, and during the whole of that time in many parts of the kingdom the bees have never seen the outside of their hives. This is not an unusual thing for the United States—at least the northern part of it; but when bee-keepers are prepared for a warmer climate, it makes the prospects for successful wintering rather dubious in England. But if such weather has prevailed in the latitude of London (51½ degrees), which is considerably north of the United States, the unusual severity of the last month is realized when we read in friend Andreu's Spanish bee-journal of the unusual prevalence of snowstorms, cyclones, and zero weather in the south of "Spain, sunny Spain." The orange-trees and kindred semi-tropical fruits are all killed. Wolves have roamed the villages, and even destroyed human life, as we learn from other sources. Friend Andreu asks, philosophically, "Is it possible for us to struggle against the north pole?"

TRADE-MARKS FOR HONEY-PRODUCERS.

There is considerable discussion going on in the bee-journals in reference to a trade-mark; and it has been suggested that the National Bee-keepers' Union take hold of the matter. The idea struck us as being a pretty good one. But here is a note taken from a private letter, which Bro. Newman very properly gives to the bee-keeping world, although he has withheld, of course, the name of the writer:

> In the matter of trade-marks, Bro. Heddon is enthusiastic—yea, eloquent in his idea of "whipping the d——l around the stump," as they say; but he does not quite hit the nail on the head. A "mark" of some kind may be taken (a label if you please) to prove membership in the Union; but will the Union warrant that every member sells nothing but pure honey? Would not one sale of poor honey spoil the

whole? Now, I do not see, first, how a trade-mark can be obtained from the Patent Office for the Union. I can not see how a private trade-mark can be a Union mark; and, again, I can not see how the Union can "back up" or warrant any member. We know there are black sheep, and there may be some in the Union. In fact, Bro. Newman, I do not see how a trade-mark can help us as a Union; but I can see how it may hurt us awfully. My idea, then, is, to let the Union stand as it is—a bulwark of defense for its persecuted members, but not as an advertising scheme for any of them. Let each honey-producer stand on his own reputation, which he can make good or bad; for by his fruits we shall know him.

These are things that we should consider; and some of the points made by the writer above are well taken.

SPECIAL DEPARTMENT FOR A. I. ROOT, AND HIS FRIENDS WHO LOVE TO RAISE CROPS.

OUR OHIO EXPERIMENT STATION AT COLUMBUS.

My good friend E. C. Green gave me a notice that they had two greenhouses full of very nice lettuce, which they were going to cut on the 29th of January. On the afternoon of that day it was my pleasure to look over their work. One of these greenhouses is warmed by pipes underneath the beds, and the other by an equal number of pipes overhead, hot water being used in each. The plan was to decide which gave the best results for vegetables under glass. So far as crops were concerned, there seemed to be but little difference; but from the fact that the overhead pipes kept the frost off from the glass, thus giving the plants more sunshine, and, in consequence, requiring less fuel, this plan is preferred. Both houses showed a degree of thrift that does much credit to the young men who have it in charge. Friend Green is a Medina Co. boy, and has taken up this work with no practical experience, and with but little instruction from any one. The work is under the charge of Prof. Thorne; and I must say that I never saw a prettier-looking greenhouse for garden-stuff in any of the large cities in any of my travels. Of course, the work is principally devoted to testing many things connected with this kind of work under glass. One bed of lettuce, for instance, is watered entirely by sub-irrigation, something on father Cole's plan. Another, right by its side, is watered by sprinkling overhead. At present, sub-irrigation has given the better crop. Various experiments were performed to determine the value of chemical manures—prominently, the nitrate of soda; and although these experiments were made with the utmost care, there was nothing in the greenhouse to indicate that the nitrate of soda had been of any advantage whatever. In fact, some beds seemed to indicate that its effect had been detrimental. Prof. Thorne said its effect on the wheat in the open air had been wonderful, without question; and he said that, if he could show the Ohio farmers the difference in the appearance where nitrate of soda had been used, he could give the sale of it one of the biggest booms that a fertilizer ever had, provided he did not at the same time tell them that the increase of crop was not sufficient to pay the cost of the fertilizer. As the nitrate of soda is being advocated through the agricultural papers in pretty strong terms, I think these experiments must prove valuable. Although we have used it to a considerable extent on our grounds here in Medina, I have not been able to see that it produced any effect whatever, unless it was on a crop of spinach outdoors; but in that case, as I put it all over the whole patch, I can not be sure that the spinach would not have been as well off without it. In raising vegetables under glass, it would, of course, pay us to use very expensive manures that we could not think of using for ordinary crops outdoors; and at the present writing I know of nothing that equals guano and lime for greenhouse work. I shall have more to say in regard to this visit in some of my future garden talks.

SPECIAL NOTICES.

ENOUGH OF FEB. 1, 1882.

Our offer in last number brought us an abundant supply of the above number, so please don't send any more.

SPECIAL 5 PER CENT DISCOUNT ON WIRE NETTING.

All orders for wire netting, either job-lot pieces or regular stock, received here not later than the 25th of this month, will be subject to a special 5 per cent discount. This is with a view of getting as many orders as possible filled and out of the way before the rush of spring trade begins. If in need of any thing in this line, send on your orders and secure the discount.

REDUCED PRICES ON THE TWO NEW BOOKS ON GARDENING.

By buying in large quantities we have obtained special rates, so that we can sell "The New Onion Culture" for only 35 cts. instead of 50, and the new "How to Make the Garden Pay," for $1.50 instead of $2.00. The above prices include postage. If ordered by express or freight with other goods, the price will be 30 cts. and $1.40 respectively. It seems to me it will pay those who are to any extent engaged in market-gardening to have both of these new books. The larger one is the most complete work on gardening under glass that has ever been published.

THE OLD BACK NUMBERS AT ONE CENT EACH.

A good many who have ordered these have almost entirely misunderstood our offer, and have specified the numbers they wanted at this rate, instead of taking just what we chose to send. The fact is, we have a wagonload or more of old numbers, mostly 8 or 10 years old, but we haven't much of a surplus of late years. We could sell these old numbers as paper-rags, but they contain very valuable matter; and by asking a cent apiece for them we should have about enough to pay for our trouble in wrapping and for the postage, and you would get a lot of good reading for almost nothing. Now, we will put the proposition this way. Old numbers of which we have a surplus will be one cent each, postpaid, in lots of 10 or more, *if you take what we choose to send*. We will send the numbers you specify, at 2 cents each, *provided* we have an abundance of them, so they can be spared without reducing our files so as to make it necessary to buy them back again. Remember, the old back numbers, *our choice*, will be one cent each; *your choice*, 2 cents each, provided we have a surplus of what you choose.

BUY YOUR EARLY QUEENS SOUTH

I will have on hand a stock of

CHOICE ✽ ITALIAN ✽ QUEENS

as early as they can be raised down here. Write for prices and particulars.

DR. TINKER'S SPECIALTIES!

The Nonpareil Bee-hive and Winter case, White Poplar Sections, Wood-zinc Queen-Excluders, and the finest and best Perforated Zinc now made.

Send for catalogue of prices, and inclose 25 cts. for the new book, **Bee-keeping for Profit.**

Address **DR. G. L. TINKER,**
21tfdb **New Philadelphia, O.**

☞In responding to this advertisement mention GLEANINGS.

Job Lot of Wire Netting.

CUT PIECES AT A LOWER PRICE THAN FULL ROLLS.

Having bought from the factory, at our own price, five or six hundred remnants, as listed below, we are able to give you the choice of a great variety of pieces at the price of a full roll or lower. Full rolls of netting are 150 ft. long, and when they are cut we have to charge nearly double the full-roll rate, because it is so much trouble to unroll, measure, and cut, and run the risk of having a lot of remnants on hand. No doubt it is in this way that the following remnants have accumulated. It costs a good deal to get all this in shape so we can easily pick out from the lot the piece you want. But to move it off quickly, we put the price down so you can all have a chance at it. Remember, first come, first served. In ordering, therefore, name a second or third choice, or say that we may send the nearest we can if the piece selected is gone. On 5 pieces deduct 5 per cent, on 10 pieces 10 per cent. These remnants are shipped only from here. If any of you want to secure some, and don't want them shipped till later, when you will order something else, so as to save freight, pick out the pieces you want, send remittance with the order, with request to lay by till called for, and we will mark them as belonging to you. We prefer to ship them right out, however.

LIST OF POULTRY-NETTING REMNANTS.

Width in in's.	Size of Mesh.	No. of Wire.	Cts. p'r Sq. Ft.	Length of each piece. Multiply by the width in feet to get the number of square feet in each piece. Then multiply by the price per foot for the price per piece.

HONEY COLUMN.

CITY MARKETS.

Albany.—*Honey.*—The demand for comb honey is more liberal since the Lenten season began, but there is no change in prices. We have had one consignment of 40 cases of comb honey and 30 packages of extracted since last report. No change in prices of extracted. We quote clover, 16@18c; mixed, 14@15c; buckwheat, 12@13. Extracted, light, 8@9; dark, 7@8.

Chas. McCulloch & Co.,
Feb. 20. Albany, N. Y.

Cincinnati.—*Honey.*—Demand is good for all kinds of honey, with a good supply on the market of all but Southern honey, which is scarce. Choice comb honey brings 16@17c a lb. in the jobbing way. Extracted honey, 6@8c a lb. on arrival. *Beeswax.*—There is a good demand for beeswax at 24@26c a lb. for good to choice yellow on arrival.

Chas. F. Muth & Son,
Feb. 20. Cincinnati, O.

St. Louis.—*Honey.*—Mild weather has affected trade so that there is scarcely any demand for either comb or extracted. We quote white-clover comb at 16c; dark, 13@14. Extracted, 6@6½ in bbls.; cases, 6½@7½. *Beeswax*, 26½. D. G. Tutt Gro. Co.,
Feb. 19. St. Louis, Mo.

San Francisco.—*Honey.*—Extracted honey is firmer, and several carloads have been sold East at 6¼@6½c, f. o. b. Comb honey very scarce, and to be had only in small lots. We quote 10@14c, as to quality. *Beeswax* in good demand at 24@25c, f. o. b.

Schacht, Lemcke & Steiner,
Feb. 14. San Francisco, Cal.

New York.—*Honey.*—We quote extracted California honey, light amber and white, at from 7@7½c. Florida honey in barrels at 7@8c. *Beeswax*, nice yellow Cuban, 28½c; Southern, 29½c; selected California, 31c. F. G. Strohmeyer & Co.,
Feb. 20. New York City.

Detroit.—*Honey.*—The market for honey is not very brisk. Comb honey is selling at 14@15c. Extracted, 7@8c. *Beeswax* firm at 27@28c.
Bell Branch, Mich., Feb. 19. M. H. Hunt.

Kansas City.—*Honey.*—We have a steady demand for comb honey in 1-lb. sections, and if receipts continue light our market will soon be cleaned up. We quote white 1-lb. comb 16@18; California 2-lb. comb and extracted slow sale. We quote 2-lb. comb, white, 14@15; dark, 12@13. Extracted, 6@7. *Beeswax*, 25c.

Clemons, Mason & Co.,
Feb. 24. Kansas City, Mo.

St. Louis.—*Honey.*—The season for the sale of comb honey is well advanced, and the demand is rather light. Choice white clover, 14@15c. Extracted, in cans, choice white clover, 7½@8c. Lower grades in both comb and extracted, lower as to quality. *Beeswax*, prime, 26c. W. B. Westcott & Co.,
Feb. 13. St. Louis, Mo.

For Sale.—2000 lbs. clover honey, in 15-gallon kegs, at 9 cts. a lb. by the keg, tare out.

Mont Wyrick, Cascade, Ia.

For Sale.—Extracted honey, in 70-lb. tin cans, at 10 cts. per lb., f. o. b. Lewis Haines,
4d Moons, Fay. Co., O.

For Sale.—1200 lbs. extracted white-clover honey in barrels or 60-lb. cans, as desired.
1tfdb E. J. Baxter, Nauvoo, Ill.

For Sale.—Choice honey in sections, cans, and C. pails. Send for price list to Oliver Foster,
12-tfdb. Mt. Vernon, Ia.

STRAY STRAWS

FROM DR. C. C. MILLER.

THE STING-TROWEL theory has gone into hibernation.

THE OLD OFFICERS of the Bee-keepers' Union are re-elected.

DIVIDED TOP-BARS are being repeatedly invented nowadays.

OUTDOOR WINTERING had a majority of votes at the Ontario bee-keepers' convention.

REDUCED FARE is a thing of first importance in fixing time and place of conventions.

WHERE ARE the one or two government stations that Prof. Cook speaks of as doing something with bees?

MR. G. DELAYEN's plan for an out-apiary is to have very large hives, and visit them only twice a year, spring and autumn.

WILL E. E. HASTY please tell us whether he succeeded in getting an improved breed of red clover? Hasty is the man to do it if any one can.

THE ONTARIO BEE-KEEPERS' ASSOCIATION reports 323 members for last year. Can you beat that on this side of the line, you bragging Yankees?

ARTIFICIAL HEAT in cellars is bad—costs too much. Artificial cold (or natural either) is still worse. If cellars get too cold, choose the least of two evils.

CARBOLIC ACID used for quieting bees, says the *B. B. J.*, was credited by the late Rev. George Raynor as the chief cause of his immunity from foul brood.

"NUMBER TWO," in *C. B. J.*, thinks I'm afflicted with *versatility*. That's not what ails me, "Number Two." It's the grippe that's got its—got its—grip on me.

LARGER BEES are advocated in the *Api.*, in the belief that doubling the size of the bee will double the distance it will travel. Does a crow fly any further or faster than a blackbird?

THE BRITISH BEE JOURNAL is publishing a series of "Bee-papers for Winter Reading." If the first number is a fair sample, the series will be valuable. In effect it will be a practical treatise on bee-keeping.

E. R. R. ASKS ME, on page 87, whether I would "preach bee legislation, priority claim of locality, or move out," if bee-keepers were too thick around me. I wouldn't do either. I'd shut my teeth tight together, and wish for the day to hasten when bee-keepers would have the same chance as farmers.

PROF. COOK found that bees fed on pure honey, or honey and syrup, half and half, lived five times as long as bees fed on Good candy made from coarse granulated sugar. Powdered sugar is the thing for Good candy.

HEATING BEES in winter is discouraged by the *B. B. J.* Undoubtedly right where zero weather is never known. But where for days it keeps some 50° below freezing, give me a steady coal fire, if my cellar is not warm enough.

A COLD DAY, E. R. R. says, makes it all right to carry in bees without bottom-boards. Yes, I know, if it's cold enough. But I want mine in the cellar before it is cold enough. So I prefer to carry in the deep space with my hives.

AN EGG of a queen is $\frac{1}{14}$ of an inch in length and $\frac{1}{70}$ of an inch in thickness. If a queen lays 3000 in 24 hours, and they are laid in a row, end to end, it will make a string about 18 feet long. Even if she didn't lay them in just that length of time, I suppose they would measure the same.

SECTIONS BY WEIGHT is the safe way. I'm beginning to favor less than a pound section; for if all are less than a pound, the public will soon learn it, and then there can be no cheating by selling light weight. The weight is too uneven to make selling by the piece always best.

LOOSE OUTSIDE CASES over hives are nothing new, according to the *B. B. J.*, and it pokes fun at us for thinking they are. It says, "We trust they will give such hives a fair trial, and that they will also find them as advantageous as we have done for the last fifteen years or more back."

HONEY, according to Prof. Cook, is digested, ready for absorption, making it a safer food for man than cane sugar, and a safer food for bees in confinement. Practice doesn't always confirm this, but there may be something wrong in the practice. It's hardly right to give the name of honey to some of the thin sour stuff that goes under that name.

A STANDARD TEMPERATURE for cellars, I'm afraid, is a bad thing. If you say 40°, some beginner will freeze his bees. If you say 45°, another will roast his. Cellars differ. Thermometers differ. Each one must find out for himself what's best for him. Better tell the beginner, "There is no standard. Hunt for a quiet spot somewhere between 37 and 50."

THE NAMELESS DISEASE is agreed to be cured by changing the queen. I'd like to see some of the "ample evidence" of it. "A number of cases and all recovered after changing the queen?" I can give just as strong proof that red paint on my shop has cured the numerous cases that I have had. I don't say changing the queen never cured a case, but I never saw satisfactory evidence of it. Mine always got well without it.

"MAKE YOUR HIVES and appliances by all means if you can, but draw the line at frames and sections. Buy them and save money, time, and temper, and secure efficiency by so doing." So says the *B. B. J.* Good advice, only I'd put "hives and appliances" on the same side of the line as frames and sections, in most cases. I'm satisfied with putting together and nailing.

FOUL BROOD can be cured by using *naphthol beta*, so says Dr. Lortet in the *Revue Internationale*. The *B. B. J.* gives a translation of his article, and speaks approvingly of the remedy, which, it says, is perfectly harmless. Dr. Lortet says, "It is the adult bee which is first infected." "Contaminated honey may be a cause of the propagation." Cheshire denies the latter.

"THE HONEY-BEE: ITS NATURAL HISTORY, ANATOMY, AND PHYSIOLOGY," Mr. Cowan's new book, is just the thing for some of you beginners to read up on, who want to be in the front ranks. It's so nicely gotten up that it is a pleasure to leaf it over. I haven't had time to read it yet; but from what I know of its author I am safe in saying it is entirely accurate, and up with the times.

THE DEPOSIT SYSTEM is an English kink. The *B. B. J.* says, "When strangers are dealing together, the purchase money of the articles is deposited at our office. We acknowledge the receipt of the deposit to *both* parties, and hold the money until we are satisfied that the purchase has been concluded." A small fee is charged. Why wouldn't that be a good thing to copy in this country?

GENERAL CORRESPONDENCE.

BEE-ESCAPES.

EXPERIMENTING WITH DIFFERENT FORMS; HOW MR. DIBBERN CAME TO DISCOVER THE HORIZONTAL STYLE.

During the 25 years that I have kept bees it has been a constant problem with me how best to get rid of the bees in the surplus boxes. I tried about all the different methods suggested in all that time, but all proved more or less unsatisfactory. But, let us try, and investigate, to see, if we can, where and what the difficulty to be overcome really was, for the thing is accomplished.

When I commenced bee-keeping we had no bee-papers—at least I knew of none—and the only guide I had was *Quinby*. He recommended leaving the surplus boxes out over night, about six inches in front of the hives, and placing a few sticks so the bees could run over the bridge to their hives. Sometimes this worked all right, but often the honey would be covered with bees the next morning, ready to go for any one coming to get it. Then, too, should a shower come up during the night, the honey would be damaged. It would also be a "shining mark" for nocturnal prowlers; and should it chance to be forgotten, or left out too long in the morning, what a picnic there would be!

The next plan suggested was to get several large store boxes and pile the surplus boxes in, bees and all, and cover over with a sheet, occasionally turning the sheet and liberating the bees. In that way very many young bees would be lost, never having marked their hives; and it was a slow and tedious way at best. It was also necessary to keep a constant watch, as a gust of wind might blow the sheet off at any time, and make lively times among the bees.

When I began to use sections and cases, I adopted the Heddon plan, smoking out all the bees I could, and carrying the rest into the honey-house, allowing them to escape at the top of the windows by having the wire screen extend some six inches higher than the windows. The objection to this plan was, that bees would be "bumming around" the room all day; and if any extracting was to be done they would be getting into the honey, and be a constant annoyance. One day I carried in a good many bees; and as it was almost unendurable to work in the honey-house, I went away a while doing other work. When I returned, there was "music in the air;" and I noticed about a quart of bees clustering at the top of one of the escapes at the window, and bees *did find their way back* into the room, and were actually carrying off the honey. This plan is also open to the objection that young bees will become lost, and it is a nuisance in every way. How strange that some of our *boss* bee-men, even editors of apicultural papers, should still cling to such methods!

Well, the next thing that seemed to offer a solution to this problem was the tent escape. This I used by piling up eight or ten cases, and placing a wire-cloth escape, fashioned like a house-roof, with an opening at the apex, on top. When I succeeded in smoking out most of the bees, it would generally clear out nearly all by evening; but often the bees would all cluster in one case, where it became difficult to get rid of them, and many young bees would get lost. When many bees were left in the cases they would often cluster at the top of the escape, and they then seemed to have no difficulty in finding their way back, carrying off the honey, and attracting other robbers.

About this time my attention was called to the Reese escape, and I was very favorably impressed with it. When a hive was not very strong with bees, it generally worked very well; but in removing cases from strong colonies, when no more empty cases were needed, the bees would often fill the entire space under the escape-board, and build comb there. They would also sometimes cluster on the wire-cloth cones, and open up communication between the case to be removed and the hive below. I was not long in deciding, that, to make a perfect escape, we should somehow have to get along with only bee-spaces. I then constructed a wooden rim ⅜ inch thick, tacking wire cloth on both sides, allowing the bees to escape between the cloth through a series of V-shaped escapes. I tested this to some extent in the fall, and it worked well. I believe this was the first horizontal bee-escape ever tested, and I have it as a relic yet.

Well, this idea opened up a whole multitude of bee-escapes. I soon saw that this original was larger and more expensive than need be, and soon boiled it down into my pear-shaped escape. This is really a very good form, and, if rightly made, will generally prove satisfactory. After I had published my invention of the horizontal bee-escape, a multitude of similar escapes at once sprang into existence. Thinking that perhaps I had not yet found the best plan on which to make the escape, I studied various designs, and finally adopted a four-pointed star, with openings for the escape of the bees at the points. I concluded that, as there were four outlets, it would greatly increase the capacity. It was also made removable, which I consider an important feature. The four large openings, however, proved a mistake, as I found that, in warm weather, the bees had no great difficulty in finding their way back through it. This is really the great danger to be overcome to make escapes perfectly successful. By close watching I found the bees would cluster on the cones, filling them full of bees, and seemed to be able to communicate to other bees the way through the escapes. After satisfying myself where the difficulty lay, I at once commenced experimenting to overcome it. I soon decided that the escape must be so made that bees could not readily cluster on it.

Remembering my original board, I again commenced with a board the full size of the hive, first making a bee-space between two thin boards, and making a series of runways and stops in it. I found it to work all right. I then began reducing the size of the escape, and kept testingthem all the time by removing partly filled supers and putting them on again. I finally adopted a size 4½x6½, beyond which I could not well reduce it, and made it removable. I experimented a good deal with them and took off all my cases, some 300. I also sent out more than 200 to other bee-keepers, and did not hear of a failure. Mine could not have worked better, and I do not see that any thing better can be desired. The idea that bees uncap any honey before leaving the surplus case is unfounded. They sometimes do, when they can go back through the escape, and will carry honey down if they have time enough. It is practically impossible for bees to return and open up a highway through my new escape. Several bee-keepers have lately reported using my escape with unsatisfactory results. I have investigated all that have come to my attention, and invariably found it was the old four-point escape that made the trouble.

THE HORIZONTAL BEE-ESCAPE.

This has come to stay; and if we have not yet obtained the best form, it will soon be here. I want to say right here, that "the war" as to the rightful inventor is over, and it is free to all. Many other bee-keepers have brought out horizontal escapes that are ingenious, and will probably work all right. Some that I tested proved failures; but that was to be expected. I am sure we have got something that will be appreciated more and more as the years roll on. Even some of our great bee-men and eastern bee-editors will have to "acknowledge the corn" after a while. I know the horizontal escape is a good thing, and can abide my time.

Milan, Ill. C. H. DIBBERN.

[The star-shaped horizontal did not work very satisfactorily in our yard; but your original pear-shaped escape works well.]

SHADE FOR HIVES.

HOW THEY PROVIDE FOR IT IN CALIFORNIA.

In foot-notes to Miss Wilson's article in Jan. 1st GLEANINGS you invite a discussion as to whether it is best to have our hives under shade-trees or not. It is a matter I have been giving some thought to of late, and I hope to see it thoroughly discussed.

In California I have never seen an apiary located under trees, though a good many use shade-boards, keeping them in place by laying on them a heavy rock. This method is objectionable, as it necessitates much extra and fatiguing work, and affords no shelter from the sun's rays to the apiarist. Permanent sheds are much better. One 5 feet high in the front, 4 feet at the rear (which should be to the south), 3 feet wide, and 75 feet long, can be built for $5.50, reckoning lumber at 3 cents a foot and shakes at $14 per thousand, allowing 50 cents for the nails, and charging nothing for putting it up, the roof to be one layer of shakes. This makes enough shade, but does not shed rain. By moving the hive to the southern side of the shed in the spring, they will get the desired sunshine. In summer, place them to the north side, and they will be in the shade all day. Under sheds, however, in order to economize, we are apt to put our hives nearer together than is good.

PECAN-TREES FOR SHADE IN THE SOUTH.

In Louisiana I once kept bees beneath a grove of pecan-trees. They make a dense shade, with branches high above the apiarist's head. For that climate nothing can be better. In California the difference in temperature in shade and sun seems to me to be much greater than in the East; and it is probable that, some days in the spring, stocks in the shade would be kept so cool as to do much less work than those in the sun.

The peach is a nice tree to plant in the apiary. It grows rapidly, and makes a shade of just about the right density. Some varieties are later in putting out leaves in the spring than others. These are the best to plant, as at that time of year the hives should have all the sunshine possible. In California, French prunes might be better than peach-trees. They are of slower growth than the peach, but more profitable when it comes in bearing. This tree has been termed the lazy man's tree, as its fruit, instead of rotting when not gathered, will dry into a marketable commodity.

Build your honey-house in the center of a two-acre orchard. Put two hives under each tree, and it will be about right for a 400-hive apiary. Scattered over so large a space, young queens will have no difficulty in locating their own home, and I believe that, in that respect alone, it will more than repay for the extra travel necessary where hives are so scattered.

One very great advantage, where hives are scattered among trees, is the lessened liability of swarms uniting, which issue at the same time. Last year, in my apiary (located on an open plat), I had 16 swarms unite, making a cluster as large as the body of a good-sized horse. Many other times I had from two to six unite. The consequence was, that a majority of my queens were killed at a time when the eggs laid would have produced workers for the main honey-harvest.

The trees should be trimmed high, both to get the branches out of the apiarist's way and permit a free circulation of air. A neighboring bee-keeper told me quite recently that his hives in the shade melted down worse than those in the sun. He had set them in some low brush, which grew thick from the ground up.

Where, from preference or necessity, hives are to be placed near each other, if the ground be planted out to a variety of trees it will better enable the bees from the different hives to identify their own home. In my apiary I am planting grapes, apples, peaches, prunes, walnuts, pears, and figs. With the exception of apples and pears, no two trees look alike.

A year ago I purchased some 300 enameled-cloth quilts for my hives. While they are good for preventing the escape of warmth from the hive, I believe those quilts have been the cause of more profanity in my apiary than the 400 stocks of hybrids, though each of which (last summer at any rate) seemed possessed of the diabolism of a thousand demons. If any wind is blowing it is almost impossible to keep the quilt spread out smooth while one puts on the top. I have often had it go sailing off ten feet or more, just as I was closing the hive. I have thought of tacking them to the cover. A much better quilt is a piece of canvas well daubed with thick paint. Its weight being great, the wind does not bother much. WM. G. HEWES.

Newhall, Cal., Jan. 13.

OUTSIDE CASES FOR WINTER.

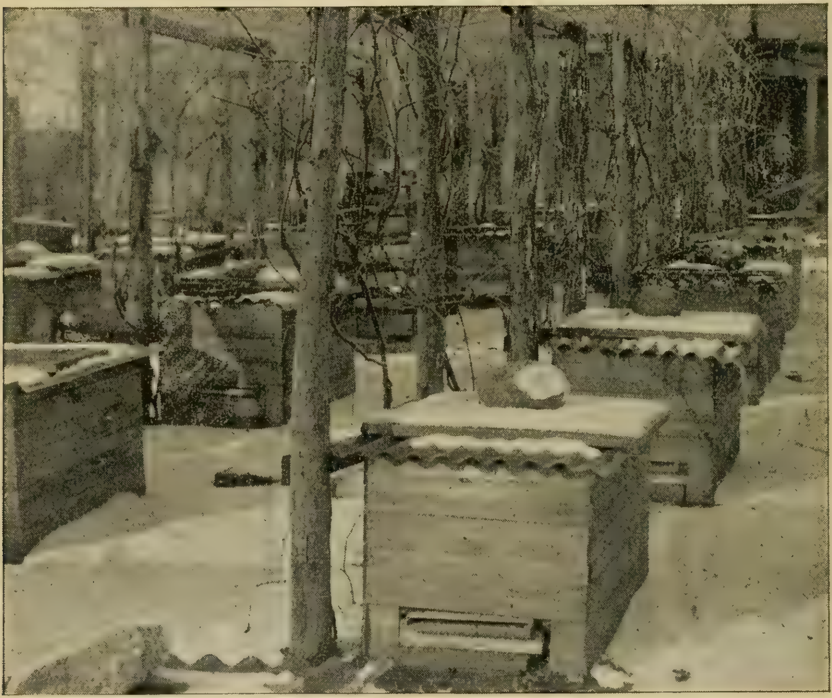
SUCCESSFULLY USED BY J. A. GREEN.

From the references that have appeared in GLEANINGS lately in regard to outside shells for packing bees that are to be wintered on their summer stands, the novice would almost be led to think that it is a new and untried device. I have used such packing-cases for four years; and at present I have over a hundred colonies protected in this way. In fact, with the exception of a few in your chaff hives, every colony that I am wintering out of doors is snugly packed in leaves or shavings held in place by an outer case. Besides this, there is a great stack of them waiting to be put over the bees now in the cellar when they are brought outdoors.

"What," you say, "do you go to the trouble of packing bees that have passed through the winter safely in the cellar?" Yes, that is just what I am going to do. I believe that it pays to protect bees, and I think there is no time when they need protection more than in the spring, when we want them to rear as much brood as possible. Thin-walled hives are too easily affected by changes of temperature at this time, and brood-rearing suffers in consequence.

To make my packing-cases I use ordinary lath cut into two pieces, 20 and 28 inches long. These are nailed to three-inch corner strips to form the ends and sides of a box without top or bottom. It is made of such height that, when set over the hive on its stand, the outer case resting directly on the ground, it will be five or six inches higher than the hive. The end pieces should be nailed to the flat side of the uprights, and two or three left off at one end for the entrance. Now put a "bridge" over the entrance, set the packing-case over the hive so that the front rests on the bridge, holding it firmly in place, and put in your packing material. This may be whatever is convenient. I generally use leaves. Soft leaves, such as those of the soft maple, are excellent. Planer shavings or sawdust are more easily handled, and better.

We now want a roof over it. Above all other qualities it must be water-tight. Wet packing is worse than none at all. I have given considerable thought to the matter of making a roof that would be cheap, durable, and effective. All these qualities are hard to combine. A very good and cheap roof may be made by nailing barrel-staves crosswise to a three-inch strip a little longer than the packing-case, putting over them a sheet of roofing-paper, then nailing on another layer of staves so as to break joints with the first ones. The most satisfactory covering, though, and the best, all things considered, is a sheet of corrugated iron, large enough to cover the whole. An ordinary sheet (96 in. long) makes three pieces just right. Nothing further is required. Just lay the sheet of iron on top, and lay a stone on it to keep it from blowing away; or, better, lay a short piece of board across the top, and the stone on that. This makes a roof that can not leak; and with ordinary care it is practically indestructible. With a coat of paint occasionally, it will last as long as the owner. When not in use they can be stored in a very small space, as they nest into one another. They make the best of shade-boards for summer, if



J. A. GREEN'S APIARY IN WINTER, SHOWING OUTSIDE PACKING-CASES.

any are desired. Cut the corners off rounding, so clothing will not get torn on them.

These corrugated iron covers cost me a trifle less than 20 cents each. A bunch of lath, costing 15 cents or less, will make two packing-cases. I think these are practically as good as if made of more expensive lumber. If you desire, you can turn them into excellent chicken-coops for summer use. If you want them more oramental, paint them with a mixture of skim milk and hydraulic cement, or other cheap paint. Really, though, I don't think they look very bad unpainted. They ought to be of a dark color, so as to absorb as much of the sun's heat as possible whenever it shines. This helps brood-rearing in the spring wonderfully. One of the principal arguments in favor of unpainted hives is, that bees build up in them better in the spring. I think this is mostly due to the dark color. With a dark outer case you have all this advantage, and more, as the packing retains the heat.

I inclose a photo showing how the hives look, packed as I have described.

I have given up the coal-mine where I wintered them for the past two winters, as it was too hard to get at it.

My apiary is just on the edge of a bluff. There is a stream in the valley—Fox River—running south. J. A. GREEN.

Dayton, Ill.

[I think you are mistaken. I did not mean to convey the impression that outside winter cases were new; on the contrary, all along I have assumed that they were old. What I desired to know was, how many bee-keepers were using a similar arrangement *now*, and, more particularly, how the so-called dead-air space compared with packing.

With your corrugated covers I should think the snow would beat in under and so dampen the packing; and there is that 10-lb. stone and board—doesn't that make a good deal of rigging? The outside packing-case that I described on page 698 last year was to cost only 35 cents, and, besides, it would be much neater. If painted muslin or roofing-paper will answer in place of tin, the cost will not be more than yours.] E. R. R.

SOMETHING ABOUT BEES AND BEE-CELLARS.

DOOLITTLE CONTINUES THE SUBJECT.

A correspondent writes thus:

> My bees seem to be wintering poorly on their summer stands, and I have resolved to build me a bee-cellar. How should it be built? how ventilated? what is the right temperature to keep it while the bees are in it? at what time of the year should they be put in and taken out? I know you have told us considerable about bee-cellars, and I know that an article on this will be a little unseasonable; but will you not be so kind as to give us some of the small points necessary along this line, and tell us about it soon, as I wish to build mine right after spring work, so it may get all dried out and ready for the bees in the fall? Give the article in GLEANINGS, as I think it will be of interest to many besides myself.

Well, I supposed I had written about all I had to say on bee-cellars during the past; but with the editor's permission I will try again.

To my mind, it matters very little how the cellar is built providing it accomplishes the purpose for which it is intended; i. e., keeping a uniform temperature inside, no matter what are the changes outside. Of course, you will want it large enough to accommodate all the bees you will ever expect to have to put in it. If it can be built in a side hill it will better accomplish the keeping of an even temperature than a cellar under a house can be made to, and this is the reason why I prefer the outside cellar, or cave. If your cellar under your house can be partitioned off so that the apartment for the bees need not be disturbed by the constant going after vegetables, etc., and so that an even temperature can be maintained, such a cellar is equally good with an outside cellar. The trouble with the cellar under the house lies in the fact that the cold and warm air, produced by the varying temperature of winter, passes through the floor of the rooms above, so that no even temperature can be kept below. If the space under the floor, between the sleepers, can be filled with chaff or sawdust, it will help much to obviate this trouble. If the cellar is dug in a side hill I would have it long and narrow. Mine is 24 feet long, 7 wide, 6 high, and is large enough to accommodate from 100 to 125 colonies, according as they are packed. From this you may know about the size you want. The cellar in the side hill has another advantage, in the fact that the path into it will be on a level with the ground outside, so that the hives can be set on a spring wheelbarrow and wheeled right where you wish them in the cellar. This one item alone would almost or quite pay for the outside cellar in the course of 20 years. Some seem to think that it is very important that the cellar be dry, so that no moisture nor drops of water ever collect on the walls or about the bees or cellar; but all of my experience goes to prove that, if the temperature can be kept between 40 and 45°, all the moisture that will naturally accumulate in any cellar will do no harm. My cellar is so moist that drops of water stand all about overhead and on the side walls of the room, yet the bees do not seem to be affected in the least by it. I am coming to think more and more that the matter of ventilation is non-important, as bees winter in splendid condition with no special provision being made for any ventilation. By way of explanation, I will say, that, when I built my cellar, I constructed a sub-earth ventilator 150 feet in length, in connection with a direct upward ventilator of the same size. Either of these could be controlled at will, and every change of weather found me changing these ventilators. After a little I began to leave the upper one closed all the while for a month, while the sub-earth ventilator was often closed for days together. Not seeing that it made any difference with the bees, I now left them closed all the while; and as this gave me a more even temperature in the cellar, neither ventilator was opened at all during the winter of 1889; so this fall, when I came to re-roof my cellar with flagging, I left out the upper ventilator entirely, allowing the sub-earth ventilator to remain, but it has been closed all winter so far. In this way I have no trouble with the temperature, as it will vary only from 41 to 43° degrees during the whole winter, or only two degrees. If you have a cellar in which the temperature falls lower than 40, I would put a slow fire in it, or in an anteroom just off from it, so that, when there is much severe weather, the temperature might be kept up at 43 to 45° if possible. A change of 10° in temperature is liable to make the bees uneasy, cause them to go to breeding, get the diarrhea, and spring dwindle. If the cellar is under a house, some seem to think that a small pipe from the chimney above the fire, running down to within two inches or so of the cellar bottom, to be used in a warm time, is a good thing in that it causes a change of air during a warm spell, which results in keeping the bees quiet with a much higher temperature than they would without this change of air. I am not positive on this point; but if I had a cellar that would run up to 50 every warm spell, I would try it. With me I consider a temperature of 42° to be the best for a cellar; but I would say that the temperature which is best is the one in which the bees are the most quiet. That may not be the same with you that it is with me; therefore I would advise you to keep watch closely; and when you find where the bees are the most quiet, control the temperature *just* there as near as may be ever afterward. Bees will be quiet in a much higher temperature during November and December than they will be during March; therefore the cellar that will cool off a little as the winter advances is much the best, providing it will not rise when the weather begins to warm up in the spring. If the bees are quiet in the cellar, do not remove them till the elm and soft maple are in bloom, about April 20 in this locality. Set them in the cellar on the approach of cold weather, say Nov. 10, and you will not be far out of the way.

Borodino, N. Y., Feb. 12. G. M. Doolittle.

FOUL BROOD.

HOW TO BURN THE CASES WITHOUT DANGER OF INFECTION TO THE HIVES.

I tried every remedy you told me of, but found nothing that would effect a permanent cure. I would be much encouraged after applying a remedy for awhile, but it would soon be as bad as ever. I became perfectly disgusted with the whole business, and nearly decided to quit it entirely. I then had 26 colonies, March, 1889, and 16 of them had foul brood. Some of them were so bad I could smell them 20 feet from the hive. I knew it would be only a short time before it would be in the rest. So I decided to try what virtue there was in fire. Don't laugh at me, and say, "That man Keith is foolish." I had become somewhat desperate. Every thing in the bee line was going to the dogs, so I had to try a desperate remedy. I dug a hole opposite each affected hive, a little larger than the size of the hive, about 1½ feet deep, and filled the hole half full of small split pine. Then I took three hives off the bottom-board, and placed them in the hole. I did this after sunset, and put fire in the hole, and soon the hives, bees, frames, and honey were all in flames, and they made a good fire. While I was watching them burning, my wife said it was a pity to lose the hives. It was bad enough to lose the bees, but to lose both was too bad. I agreed with her. I got my smoker and filled it up with nice dry wood, and got it in full blast, and put a handful of pulverized sulphur in the smoker, and went to the other affected hives and killed the bees with the smoke, then I put dead bees, combs, honey, and frames in the fire, and burned them up. Then I had the hives well scraped, then scalded with water, then well fumigated with sulphur; so, at my wife's suggestion, I saved 13 hives; and by the process mentioned I am entirely clear of foul brood. I have not seen the least indication of it since March, 1889. And I believe it is the only effectual way to rid an apiary of the disease. I have now 37 colonies in good condition, apparently healthy, and I hope to increase to 50; then I shall have as many as I want, and hope to make a good crop this year. Now, friend Root, if you can suggest a better remedy for foul brood, let me hear from you. J. J. Keith.

Louisville, Ga., Jan. 15.

[It is not necessary to kill the bees. We have cured all we had that were diseased, with the exception of a few that we at first destroyed with fire, by scalding the hive with boiling water and putting the bees in clean hives on frames of foundation. After the bees have consumed all the honey in their sacs in comb-building, they are free from the last vestiges of foul brood. If you discover that you have one or at most two cases *at the start*, it may be advisable to burn them as you describe.]

PAINTED MUSLIN VS. TIN FOR COVERS.

SUGGESTIONS FOR THE DOVETAILED HIVE.

On page 69, muslin versus tin covers are mentioned. You are the man who advanced this idea way back in the 70's in Gleanings. Then as now such covers were a success with us.

A MUCH CHEAPER COVER.

Muslin on a wooden stretcher, or frame, portico like, with two coats of paint, is an excellent cover, but it will not stand hailstorms. The cover of the Dovetailed hive is just the thing for a painted muslin protection. Then the hive has the needed shade in summer, and will be water-proof.

You should make some improvements yet on the Dovetailed hive and closed-end frames. The end-pieces of the frames should be ¼ inch from the hive. The frames should not rest on the bottom-board: it will be a moth-nest if they do. Could you not send a frame-rest with each hive? This rest can be made of half-inch (½x$\frac{3}{32}$) hoop iron or steel. The main object in setting the end pieces of the frames back ¼ inch is to have a cooler hive in summer and a warmer one in winter. Queen-excluders should have quarter-inch passage-ways on the ends also, to enable the bees to ascend and descend from the super.

The other day I had a Bay State hive shipped by Mr. H. Alley. Indeed, it is a neat and superior hive. It may become a pet hive with all bee-keepers who keep bees on a small scale. For others, too many screws! I can handle all sections in a Dovetailed super before an ordinary bee-keeper will have cared for one frame in the Bay State super. It may be because I am a hard Democrat, or that the Bay State hive has too many fixings. A bottom-board should be one plane—all hills and valleys should be avoided—and I fear the Bay State hive has these uneven faults in some degree.

Rev. Stephen Stenger.

St. Meinrad, Ind., Jan. 20, '91.

[Yes, I knew the senior Root used painted cloth years ago; but the *junior* Root wished to ascertain whether they were used anywhere with success *now*. So far the testimony for the painted muslin vs. tin has been favorable. *If* it will answer for outside winter cases to set over in lieu of tin, it will not only be much cheaper, but far better. *Tin* is too good a conductor of heat and cold; and some of our outside cases, on examination, showed early this fall that great drops of water had collected on the under side of the tin. To remedy this, I put Simplicity covers on top, and that fixed it. Well, now, painted muslin is a good *non*-conductor of heat and cold, and, if sufficiently durable, will be better than the tin. See? Both the tin and muslin will have to be painted; but the cloth holds the paint better than tin. As to expense of material, the cloth would cost about one-fifth as much as the tin, making the expense of the outside cases from 25 to 33⅓ per cent less. But some will say, tin will be cheaper in the long run. Very likely, for regular hive-covers; but for winter cases the cloth will be warmer. Of course, either the tin or cloth should be supported by ⅜ lumber beneath.

About the bee-space between the closed ends and the hive end: The majority of bee-keepers would oppose you strongly on that point (see page 87, last issue, for a sample). The reason is this: If bees have access to both sides of the closed ends, they will gum them together that much harder. To make closed-end frames readily movable, the bees should have access to the cracks between the uprights on the *inside only*.

Your frame-rest for the bottom-board might do; but isn't it too much rigging?]

ABOUT CLOSED-END FRAMES.

IS THEIR USE IN A TIGHT-FITTING CASE, A LA HEDDON, NEW?

Near the close of the honey season of 1878 or '79, while taking sections of honey out of a super that held a single row of sections like one apartment of Moore's crate, it occurred to me that brood-frames could be constructed to fit in a hive in the same way. In a few weeks after I first thought of such a hive, I constructed one with closed-end frames, and with the ends of the frames fitting against the ends of the hive. In the fall of 1879 a hive of this kind was exhibited at the Smithfield fair; and in the next spring, about a dozen hives of that kind were made and sold. I had used closed-end frames prior to the construction of this hive, but they did not fit against the ends of the hive, and they were used for the extractor only.

Starting with one hive in 1880 I have added to the number occasionally till I have probably more than 20 of that kind in use now. I prefer that the ends of the frames shall not exceed a scant $\frac{3}{16}$ inch in thickness. That thickness is all that is required for strength; and the thinner the ends, the less trouble there is in the way of pinching bees between the edges when frames are replaced in the hive.

It is important that the frames shall have very little "end shake." When a part or all of the frames are taken out of the hive, bees will crawl up on the end of the hive; and, in replacing the frames, if there is as much as $\frac{1}{8}$ or $\frac{3}{16}$ end shake, some of the bees will be caught and rolled in between the end of the frame and the end of the hive. If the frames have not more than $\frac{1}{16}$, I prefer $\frac{1}{32}$ end shake. The bees will be shoved out of the way, and, with a little care, the hive can be closed without crushing bees. By using wire nails, and nailing through the thin ends into the tops and bottoms, we have a good, cheap, invertible frame. The frames stand on a strip of wood nailed against the ends of the hive at the bottom, and the tops of the frames are even with the top edge of the hive. In tiering up the strips on which the upper frames stand, cover the upper ends of the frames below. The entrance is at one side of the frames, and a follower is wedged against the other side of the frames, the bees being excluded from the space at the back of the follower. In connection with a top-bar of proper width and thickness, this arrangement probably reduces burr-combs and propolis to a minimum.

R. M. REYNOLDS.

E. Springfield, O., Feb. 10.

P. S.—The details on first page are important, for the reason that Heddon claims that his patent covers the close-fitting case. If you don't care to publish this, please return it.

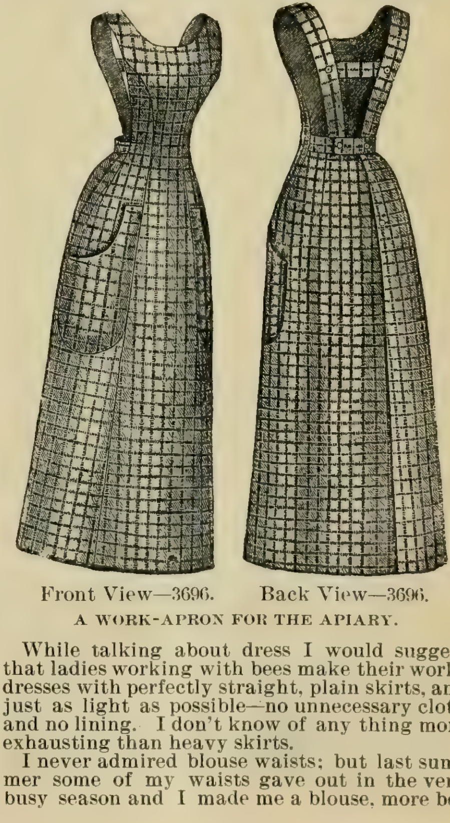
R. M. R.

[I am free to say, that Mr. Heddon is progressive, and one of the few, I think, who are able to pick out the few good things in the rubbish of bygone days. He was the first one to give me an insight into the possibilities resulting from the use of fixed distances. But there are one or two things which I feel need correction. If he is claiming broadly that he was the first one to suggest the use of closed-end frames in a tight-fitting case, he is greatly mistaken. I have known for some time that he was not a prior user of this combination. I found one place where it had been used in York State for a good many years, and I heard all around that it was an old idea. Mr. R. M. Reynolds, of East Springfield, O., whose letter appears above, gives us ample proof of the oldness of the idea. The two things—closed-end frames and tight-fitting cases—are so suggestive of the combination that it would be strange if it were not originated years and years ago. I have no doubt that this letter will call forth similar ones from others; but I have no disposition to stir up controversy, only that credit should fall where it is due. That no one may accuse me of hiding behind the editorial *we*, I come out under the singular form of the pronoun, and sign myself E. R. R.]

BEE-DRESS FOR LADIES.

THOSE DOOLITTLE CELL-CUPS, AGAIN.

Since writing about aprons I have found a very pretty pattern for my bed-ticking aprons. I send you a picture of it. You need not smile. Even a bed-ticking apron will look much better if made up neatly than if fashioned after a clumsy pattern. I like to look neat, even when taking care of bees. Don't laugh, Mr. Root; I really do, although I had reached such a dilapidated condition the day you visited our apiary.



Front View—3696. Back View—3696.

A WORK-APRON FOR THE APIARY.

While talking about dress I would suggest that ladies working with bees make their work-dresses with perfectly straight, plain skirts, and just as light as possible—no unnecessary cloth and no lining. I don't know of any thing more exhausting than heavy skirts.

I never admired blouse waists; but last summer some of my waists gave out in the very busy season and I made me a blouse, more because it was quickly and easily made than for any other reason. I found it so very cool and comfortable that I made several and wore them the rest of the season. They are very easily laundried, which is quite an item. so you can afford a clean one every day if necessary. I do not imagine they would be very becoming to stout people: but for slender ladies they do very well. At least, try one and see how you like it.

I nearly always wear a worsted skirt of some kind with mine, having it made perfectly plain, without lining, finished at the bottom with a deep hem. Then they can be laundried if necessary; but you will find they do not need it very often if made of some good serviceable color. If you get a spot or two of honey on, just sponge them off, and it is all right. I find the blouse waists very economical, as I can wear out so many old dresses in that way.

I am very anxious to know why we failed with Mr. Doolittle's artificial cups. I can hardly think it was because we did not handle the larvæ carefully enough, for Dr. Miller has successfully practiced for years the transferring of larvæ to queen-cells of the bees' own making, when he wished them to rear from imported stock. We tried as many as five colonies at a time, giving to each from ten to twelve cups, after they had been made queenless and broodless for 24 hours. The only two we did succeed with were reared over a queen-excluder, with a good laying queen below. We tried to follow directions minutely, and they certainly did look nice enough, when ready for the hive, for the most fastidious bees to use. But for some reason they preferred not to use them. These same bees started cells quite readily on the Alley plan. Now, I have an idea that it was either the cups or the royal jelly that was not quite right; but what the trouble was, I am sure I don't know. We used the jelly from cells nearly ready to seal, and carefully stirred it with a toothpick as directed, being very careful to get about the amount in each cell that is given in Mr. Doolittle's book. The cells were carefully prepared according to directions; still, there may have been something about them not quite right. It sometimes takes very little to throw things all wrong. I never for an instant doubted that Mr. Doolittle made a perfect success of it. The thing that bothered me was that *we* couldn't, and we did try hard too.

Marengo, Ill., Feb. 3. EMMA WILSON.

[The picture which Miss Wilson sends us was taken from Butterick's *Delineator;* and as it seems to be just the thing, we are glad to re-engrave it. Any lady who desires to make it needs only to call for pattern No. 3696, at any of the stores where Butterick's patterns are sold. If they can not be obtained in your village, write to the Butterick Pub'g Co., New York. The price will be only nominal. We shall be glad to have our lady bee-keepers try it, and report what they think of it. The apron provides for no sleeves, it is true; but I believe it is more convenient to have detachable sleeves—if this is what you call them—as described by Miss Wilson in a former article, page 10, Jan. 1.

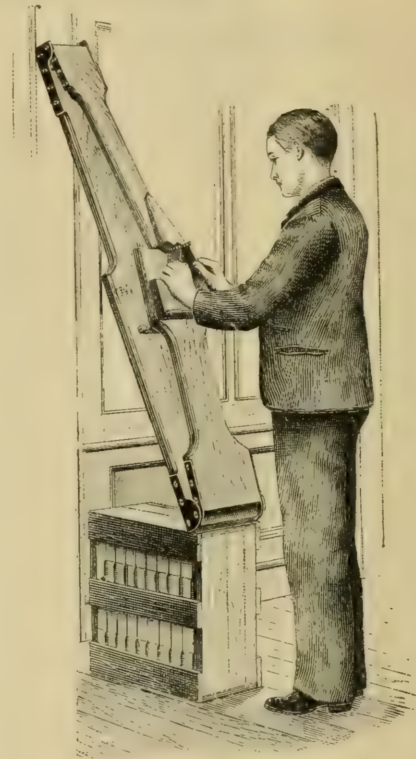
No, Miss Wilson, we will not make fun of you, even if you do make an apron of bed-ticking, of such a neat pattern. Those large pockets will be very handy for small tools, bee-brushes, handkerchiefs, etc.

In regard to those artificial cell-cups, we shall be glad to hear from those who have made them a success; and perhaps by discussing the matter a little, we shall find where the trouble lies with some of us. Even our boys here at the Home of the Honey-bees were not entirely successful with them.]

THE HUBBARD SECTION-FORMER.

AN EXCELLENT DEVICE.

A few days ago we received a letter from Mr. G. K. Hubbard, of Ft. Wayne, Ind., to the effect that he had sent us one of his section-formers by express, prepaid. He also expressed the conviction that we would be well pleased with it, and desired us to give it a thorough and most careful trial. The machine came to hand, and subsequent testing showed that Mr. H. was not far from right.



HUBBARD'S SECTION-FORMER.

The engraving shows the manner of operating the device. The operator should have an empty basket on his right-hand side; and on a stool at the left should be placed a box of sections ready to be folded. Both basket and box should be near at hand, so that all unnecessary reaching may be avoided. To operate, pick up a section, draw the two ends together, insert it in the section-former, and with a quick, gentle push, against the bridge, as it were, the corners will be crowded together quickly, easily, and neatly. Throw the section into the basket, and pick up another blank from the basket. The levers are so long that but very little power is required; and we find, by operating it in our establishment, that it is the best and easiest machine we have ever used; and, besides, it does the nicest work. Why, it is such a pretty thing to operate that I could not resist the temptation to fold up half a box of sections, just for the fun of the thing. The machine is so constructed that it is adjustable, so as to be made to squeeze the sections hard or easy. For particulars, apply to Mr. Hubbard, as above, or it can be obtained of us. See Special Notices.

E. R. R.

HOW TO BE YOUR OWN CARPENTER, ETC.

DR. MILLER GIVES US SOME VALUABLE THOUGHTS IN THIS LINE.

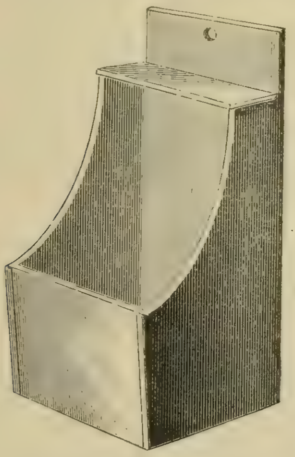
I like the "Practical Hints" on page 20. May I say something in the same line? Friend Root says, "Put a ten-cent knife in each pocket." Of course, he means in one of the pockets of each pair of pants, so that, if you forget to change when you change your suit, you will not find youself without a knife. It may seem a little thing to quarrel about 5 cts. in the price of a knife, but I never saw a ten-cent knife that was satisfactory. I generally have two or three of the fifteen-cent Barlow knives, and you can keep on them an edge as keen as a razor. The only trouble is, they are so high-tempered that, if you are not careful, you will break nicks out of the edge in whittling hard wood. As they have only one blade, I carry another knife for its small blades.

"Almost any sort of saw will do if you keep it in order." Yes, "if you keep it in order." But the trouble is, every sort of saw can't be kept in order. I paid a dollar for a saw that isn't worth a dime—so soft you can't keep it sharp. It's economy to get good tools.

"A sharp leadpencil in each pocket." It may be tolerably sharp just at the point, but you can't carry in your pocket a pencil with any thing but a very short point. If you do, it will break off.

"Never saw a board off without a mark made with your try-square." I think that hardly means to use a try-square on a board a foot wide. The carpenter's square for that.

Driving nails is so important a part of a bee-keeper's work that it is worth while to say a good deal about the minutiæ. I have had much experience in it, and yet I suspect there is much for me to learn yet. I'd like to find a good book on driving nails. Friend Root speaks of a hammer that suits you, and an assortment of nails. I'm sure he'll tell you that you need an assortment of hammers just as well as an assortment of nails. A hammer fit for a six-inch spike would be a poor thing to drive a half-inch nail; and a hammer just right for a half-inch nail wouldn't drive a spike at all. An adze-eye hammer is the cheapest in the long run. So is a good-priced hammer. A cheap hammer with a soft face is a nuisance. In a little while it is all battered up and one-sided.



DR. MILLER'S NAIL-BOX.

Have your nails where you can pick them up handily. Don't try to use them out of the paper in which you bought them. If I am doing a long job of nailing, I like a saucer to hold them. For very small nails a plate is good, having on it rather few nails, so that they will lie scattered so as to be easily picked up singly. Sometimes I am doing a long job of nailing, having no convenient place to put my nails without danger of tipping them over, and a lot of spilled nails is somewhat trying on the temper. In such case I often use the cover of a large blacking-box. Drive a ¾ nail down through the blacking-box cover, so as to hold it firmly in its place, even if it stands on the edge of an inch board. But for a regular place to keep my nails I have a set of nail-boxes hung on the wall. I got the idea from seeing some metal ones in a tin-shop. I put nails in the wall to hang them regularly upon, beginning at ½, ⅝, ¾, and so on. I am sorry to say, that so many have been handling them that they are not all now in their places. Mine are made of wood, just such as I had most handy. They can be varied in any way, but the general principle, I think, you will like. Mine are made of ¼-inch stuff, division-boards of Heddon supers.

1 piece 10½x4¼.
2 pieces 8x4¼.
1 piece 4¾x4¼.
1 piece 4¾x3.
1 piece 4¾x1¼.

Nail the two pieces that are alike on the long piece, letting them come flush at one end, then on that end nail the largest piece that is left. At that same end, nail on the piece three inches wide, and at the other end nail on the remaining piece, letting it come close against the long piece. I used ¾-inch wire nails to make them, putting them in about ¾ of an inch apart. Then whittle out the sides where nothing is nailed on them, and make a hole in the projecting end of the long board, by which to hang it on a nail on the wall. It is always ready for immediate use. All you have to do is to take it from the wall, and lay it on the long side, giving it a shake to bring some of the nails down on the bottom (or back).

If you have a lot of stuff cut ready to nail together, the sooner it is nailed the better. The ends dry out, and then it will split in nailing. I once had such a lot of stuff that had lain a year or more, and, no matter how careful I might be, it would split in nailing. I then got a tub of water, soaked the ends three or four hours, and had no trouble. Of course, all the ends had to be soaked alike or they would not fit.

If a nail needs to be straightened a little in driving, do it with the claw of the hammer.

If you have any difficulty in driving straight enough so that nails will not come out at the side of your board, let the board have its edge toward you. The eye will detect any variation from side to side, but will not easily tell if the head of the nail bends to or from you.

Marengo, Ill., Jan. 6. C. C. MILLER.

[Well, well, doctor! who would have thought that you knew so much about driving nails, and making things? Why, I always supposed that you kind o' stood around and let other folks do the work—at least, when it came to nice carpentering. Why didn't you show me those nice nail-boxes? Who in the world studied up that idea of tipping the nail-box over on its back (like laying the baby on the floor, for instance) so the nails would scatter down, one at a time, and not prick your fingers? I am *sure* you might have that nail-box *patented*. Now, doctor, the ten-cent knives that I talked about have exactly the same steel in them that the fifteen-cent Barlow does. You are just like ever so many bee-keepers. The Barlow knife is your *hobby*, and therefore you have got it into your head that no other knife will even whittle. Never mind; it is not a very bad hobby, after all. In regard to saws, I do not think I ever had one that would not do good work if it were properly filed and set. It may be, however, that hard seasoned wood like oak might turn the teeth of a soft-tempered saw. Carry an *automatic* pencil, of course, and just slip the sharp point back into the tube when not in use. Your hints on driving nails all commend themselves to good common sense. Why, doctor, you have told me a good many things that even *I* did not know before. Isn't that wonderful? Your suggestion as to the cause of the wood splitting when the nail is driven near the end is also new to me. Nothing vexes me much more than to see wood split in nailing; and yet I have sometimes thought that there was no help for it except to get the bradawl, and you coolly inform us that we can have a perfect remedy by soaking the ends well in water. I presume you forget, doctor, that our price list pictures a nice assortment of hammers, all the way from one small enough to drive a common pin its whole length into a pine board, up to the size of one that will drive a forty-penny wire nail.]

STILL ANOTHER OUTSIDE CASE.

HOW IT IS MADE, AND ITS SUCCESS.

How to convert the Dovetailed hive into a chaff hive quickly and cheaply: Make the bottom-board 19x25, so it will project 2½ inches on all sides. Now make a box 19x25 one foot high, without top or bottom, of half-inch lumber. Take off the summer cover, but leave on the honey-board. It is *better* than a Hill device, for it excludes mice. Spread a piece of burlap over the top; set this outside rim around the hive, and there is a space of just 2 inches between the walls all around for the chaff. Of course, a bridge should be fixed at the entrance so the bees can come out and fly.

For a cover, use the gable cover and you have a hive that is cheap yet handy.

I do not go into details, because it is not necessary. The average bee-keeper is intelligent enough to make them to his own fancy. I have packed bees this way for three winters, and have yet to lose a colony; while those I wintered in the cellar would die in midwinter, or spring dwindle if they happened to pull through. It is less work to pack them in the fall than it is to carry them into the cellar and out again, and then pack them for spring protection. They will eat more honey out of doors than in the cellar, but they are stronger, more energetic, and will gather enough more the following season to more than pay for extra food used in wintering. Strong colonies, ripe honey, chaff packing, and upward ventilation, constitute successful outdoor wintering in my locality.

RESULT OF THE SEASON.

I had eleven colonies, spring count; 22 by natural swarming. I obtained 200 lbs. of comb honey, 400 lbs. extracted. All the bees are in splendid shape for winter. Although I had less than half a crop, I feel more like rejoicing than complaining, considering the utter failure of others. Captured 7 first and 6 second premiums at our county fair—$12.00. H. L. HUTCHINSON.

Mayville, Mich., Jan. 24.

[Last fall we put about a dozen colonies, packed almost exactly in the way you describe with the exception that the bottom-board does not project. The shells, or rims, are pushed into sawdust around the bottom-boards. They are working nicely so far, as also are the 28 in the dead-air-space shells.]

HILTON'S LETTER.

WHAT I SAW AND HEARD IN GRAND TRAVERSE COUNTY.

Bro. Root:—I think while we were at Detroit you said you wished I would write up my visit "up north." Well, after looking over the enterprising town of Traverse City I wended my way down that historical peninsula now known as Peninsula Township. This wonderful piece of God's footstool is eighteen miles long, and will average perhaps one mile wide. There is but one road, and this runs in a romantic way, now on the ridge overlooking two of the most beautiful bays I ever saw, the water being so clear that you can see the bottom at a depth of twenty feet; then we are driving along close to the water's edge, or, if you please, in the water, for the shores are so shallow and pebbly that you can drive almost anywhere. At the extreme point is what is known in history as "Old Mission." It is now one of the finest fruit-farms in the State, and has recently been sold for a fabulous price. The whole peninsula is fast becoming one of the finest fruit and honey belts in this grand State of ours. One peculiar feature to me was, that, the further down the peninsula you go, the heavier the timber and soil become.

My first stop was about two and a half miles from the city where lives our genial friend J. P. Berg. He has a bright family, consisting of a wife and five children. I found them all as busy as beavers, and I came away convinced that they would never rust out, either in things pertaining to this world or the next. Friend Berg has about forty acres devoted to fruits of every kind adapted to his climate and soil. Space will not permit me to enumerate them here. He also has about 75 colonies of bees. About half of these are in single-walled hives, in the finest cellar for the purpose I ever saw. The rest are in chaff hives on summer stands; but he informed me he would eventually put all into chaff hives, as they wintered better, and were strong earlier in the spring. With the short seasons they have there it is absolutely necessary to have them strong at the beginning of the honey-flow. Mr. Berg has a number of your Dovetailed hives, and thinks that, as a single-walled hive, they stand at the head.

THE HOME OF MR. BERG.

At supper time I was asked to give thanks, and was both pleased and surprised, as soon as I said "amen," to hear the eldest daughter, then the next eldest, down to the little tot that could not talk plain, ask a blessing in their own language, German. I stayed with them two nights, and each morning was asked, after breakfast, to read. I selected from my favorite book, Luke, and occasionally stopped and talked of the events therein recorded, after which Bro. Berg offered a fervent and eloquent prayer. This was followed by the children, as at the table.

As friend Berg is a subscriber to GLEANINGS, and, if printed, this will come to his notice, I hope he will not feel that I am intruding upon the sanctity of his home. Would to God there were more such!

In the morning, "old Grey," a noble animal, was brought to the door before the fruit-wagon, and I was started on my journey down the peninsula. My next stop was at Mrs. N. H. Johnston's. She has, I think, about 60 colonies of bees in single-walled hives, and they were all snugly tucked away in the cellar. I understood her bees were blacks and hybrids; but she assured me the greater part of her honey came from red clover, and that her bees would leave the white clover for the red.

After a pleasant visit here I journeyed on to Mr. Wm. J. C. Davis' home. This is about twelve miles down the peninsula, and situated on the shores of the south bay. Mr. Davis has recently moved from Wexford County; has fifteen colonies of bees, and shows his preference for Italian bees and chaff hives. They insisted on my staying to dinner, and here for the first time I ate red-clover honey gathered by the honey-bee. I have robbed bumble-bees' nests. Mr. Davis fully confirmed all Mrs. Johnston said in regard to the bees working on red clover. He is an intelligent, well-read man, and he assured me the floweret of the clover grows shorter there than further south, making it possible for any bee to work upon it.

Mr. Davis is well protected by high hills on the east, west, and north, and is fast getting his farm into fruit. His place is especially adapted to early gardening, with no fear of drouth, as he can turn a spring brook across the place almost anywhere.

There are many strange and wonderful things on and around this peculiar strip of land, that I should like to talk about, but space forbids. Perhaps I can at another time. On one little spot out in the north bay lives the Robinson Crusoe of Michigan. The land is not located on the maps, consequently he pays no taxes, and can not vote. His history as it comes to me is an interesting one. I should have very much liked to visit him and several others who keep bees on the peninsula, but my time would not permit. But I am going again some time, and in the summer if possible, for it must be a veritable paradise then. GEO. E. HILTON.

Fremont, Mich., Jan. 23.

[Friend H., we are very much interested in that wonderful peninsula; and it rejoices our hearts to know of all such Christian homes as you describe. And, by the way, we want to know more about the Robinson Crusoe of the State of Michigan. There are quite a few of us who have not yet forgotten the enthuiasm with which we read the real Robinson Crusoe.]

AIR-SPACE VS. PACKING.

EXPERIMENTS, WITH THE RESULT IN FAVOR OF THE AIR-SPACE.

I made and used chaff and double-walled hives for several years in Southern Indiana. I made the best chaff-packed hives with three to four inch packing of oat chaff, and made some with dead-air spaces of the same spaces, and I found that bees did as well in the air-spaced hives as in the chaff-filled ones; and, further, in damp weather the air-spaced ones were the dryest, and emitted no damp or moldy smell. They were all furnished with tin roofs, well painted, and the walls of all were well painted with white lead and oil. Subsequently I reduced the air-space to two inches, using a partition of building-paper, making two spaces of one inch each, which I found did better than either of the others.

I came south to Florida, and did no more in experimenting with the make of hives until lately, when I have been experimenting some again with double-walled hives here, and I find them very profitable even in this climate.

DEAD-AIR SPACE FOR REFRIGERATORS.

You have no doubt observed the double glass in some of the coach windows, and that no frost will form on such double-glass windows, and it is the same with the thin wooden walls. I have also made a few small refrigerators with thin walls with several spaces of about ⅛ inch, made by using building-paper, and I find that a given quantity of ice will keep as long as in any packed walls of even double the thickness. I have also observed, in brick walls of dwellings, where the walls were laid up with a hollow wall, or a space of about two inches, with just sufficient tie-brick to keep the two walls secure, that the walls are drier in wet weather, cooler in hot, and warmer in cold weather, showing, beyond a practical doubt, that dead-air is a better non-conductor of cold, heat, and moisture, than any packing that we can practically use, and certainly it is the cheapest.

CARRYING POLLEN IN FLORIDA.

Our bees have been busy most of the time since Christmas carrying pollen and honey from the maple, which is in bloom. It lasts here usually about six weeks, and starts the bees to breeding very nicely. The willow comes in about the first of February, and will reach to orange bloom in March. This is a very favorable location for bee-keeping along the St. John's River. We have had considerable cold this winter, with some frosts, but none severe enough to damage the orange-trees or the fruit on the trees.

THE CONTEMPLATED U. S. EXPERIMENT STATION FOR THE SOUTH.

It appears from reports sent out that the U. S. entomologist contemplates establishing an apicultural experiment station somewhere in the South. It would be a great help to Southern bee culture, as we are left almost alone here to work out our own destiny, and that of our bees. We are unable to make experiments alone. Here in South Florida are vast fields of research, open for the experimenter. The season is much longer here for such work as breeding and the crossing of the races, and early enough to rear queens and send north to test as to their good qualities; and, further, there could be places where the different races could be reared in absolute purity, as here are many islands around the coast of 1200 miles where their isolation would be absolute. J. CRAYCRAFT.

Aster Park, Fla., Jan. 17.

[Friend C., I am very well aware that double panes of glass, especially if the glass is puttied in, will make an air-space that is better than if the space were filled with chaff—or just as good at least. A hollow wall made of bricks and mortar is right in the same line. It is practically air-tight. The air can not change places with that on the outside. I suppose a bee-hive *could* be made out of lumber, with a dead-air space nearly air-tight. But if you use boards wide enough for the side of a hive, they will be quite sure to check, sooner or later. Then the frost gets through, and the air inside circulates with that outside, so the temperature is about the same. With our chaff hive, as I have so many times said, we prefer the walls made of narrow strips, somewhat corn-crib fashion. This is to admit moisture to pass out freely, just in the same way the old-fashioned straw hive permits the moisture from the bees to work through, and just as woolen clothing lets the perspiration from our bodies get through. But without the chaff packing, the air, moisture, and every thing else would get through altogether *too* fast. Now, by filling this space with loose dry chaff, air can still get through, but very slowly, just as it gets through the woolen clothing on our bodies, through the fur of animals, the sawdust used in an icehouse, etc. Now, if we can make hives with dead-air spaces so as to answer just as well as chaff, will they not cost more money? and at the same time do we not lose this desirable quality in a bee-hive that we have in the old-fashioned straw bee-hive, and all porous nonconductors of heat, such as I have described? If an ordinary chaff hive will winter bees, and enable them to breed up in the spring during a series of years just as well *with the chaff left out* as with it in, then there is no use of putting chaff in any longer. May be we had better ask the experiment stations to institute some tests. Here is a point for friend Larrabee and Prof. Cook.] A. I. R.

THE BEE-KEEPERS' UNION.

SHALL IT BE UNITED WITH THE N. A. B. K. A.?

As a member of the Bee-keepers' Union, I say *no.* The two associations don't belong together. The N. A. B. K. A. is composed for the most part of annual members who join when the association happens to meet in their neighborhood. There are a few who go every year, but the number is very small in comparison to the number that belong to the Bee-keepers' Union, and the latter has not one-tenth part of the members that it should have. I don't see why it is that so few bee-keepers are willing to join, when the Union has done so much to defend our rights. Every bee-keeper in America is benefited by the Union. Then why not join and help the good work? Just put in one dollar a year, and be in a position so that, if you get into trouble, you can call on the Union to help you to defend your rights.

There is a great deal of prejudice and superstition about bees, and many think that the bee-keeper is stealing his living from other people's property. They claim the bees have no right to come on their land to gather honey. The land is theirs, the crop is theirs, the honey is theirs, and we have no business to let our bees go on to their land to gather honey. If the bees take the honey, the pasture is not as good, or the hay has lost a valuable part of its nutriment if the bees take the honey out. Some men kick because the buckwheat failed. They say the bees blasted it by taking the honey; others say the bees have spoiled the apple crop. Some say the bees injure the corn crop by working on the tassels to gather pollen, and there are a great many other things that I hear advanced every year—just such nonsense about something in connection with the bees. Now, let one of those supertitious men get mad at you. He wants to spite you somehow, he doesn't care how. If he thinks there is a possible show for him to make a case he will sue you for damage done him by your bees. All there was to the Freeborn case was spite and ignorance. The man claimed that Freeborn's bees worked on his clover, and kept his sheep away so the sheep became poor, and died the next winter in consequence. This was the first case that the Union had to deal with, and was thrown out of court, giving the Union its first victory. The Union has had several cases since then, all victorious. If you join the Union, you are entitled to help in case you are sued by any of these ignorant chaps. We ought to have 5000 members; then we should have a sum in the treasury that would command respect. Now is a good time to join. Commence with the year. Send your dollar to Mr. T. G. Newman, 246 Madison Street, Chicago, and become a member of the Union. Do it now, before you forget it. In union there is strength. A man may be a bee-keeper and be a poor man. Now, you see some of his spiteful neighbors may take a notion to pitch into him, knowing he is poor, just to annoy him and make him expense. But if they knew he belonged to the Union, and he had an army of bee-men to fight the battle with him, they would let him alone. There have already been several threatenings hushed up because the bee-keepers' enemy had to look the Bee-keepers' Union in the face.

About the N. A. B. K. A., I think it is a good institution. I am sorry that I have not been able to attend the meetings. But it costs money to go, and this year money was scarce with us. About a dozen of us tried to get cheaper rates on the railroad, but failed, and so did not go. Next year it is away down in Albany, and, of course, but few from these parts will be there, and so it goes skipping about from one place to another, all over the continent. Well, that is all right. The very name of the association calls for its moving about from place to place. But, no matter where the meetings are held, we can all get the proceedings in printed form, and I value these very highly. But unless we attend we miss the social part of the meeting, and the social part would be a big treat to me. But I don't see how we can mix these two institutions together. They are very different. The Bee-keepers' Union doesn't have to meet anywhere to carry on its business. We pay our dues, and elect the officers by ballot. All is done through the mail. I don't see how the Union could be benefited by a union with the N. A. B. K. A. Will Dr. Miller, or some other one who advocates the plan, explain?

HONEY-PACKAGES FOR EXTRACTED HONEY.

In Feb. 1st GLEANINGS, page 96, Messrs. Hildreth Bros. & Segelken recommend kegs, half-barrels, and barrels, except California, and I don't see why California should be an exception. The editor says, in his remarks, that square cans must be used in California because the climate there will shrink the wooden packages. In fact, kegs would be utterly useless with them. With the experience that I have had with kegs and barrels, I am positively of the opinion that it is a mistake that Californians can not use kegs or barrels for honey. If the barrels are made from perfectly seasoned white oak, or some other timber as good, no soft timber, and hooped with heavy iron hoops, then season the barrels six months in an upper story of some good weather-tight building, then drive the hoops, and see that the barrel is tight, air-tight (don't put any water into it), you are all right. Now, if your barrel is air-tight you can easily find it out by blowing into it with your mouth through the vent-hole. Blow in all the air you possibly can, and then slip your finger over the vent and hold it there tight for a minute or two; then take off the finger. If the barrel is tight, the air will come out whistling. You can put honey in that barrel in California, and ship it or keep it as long as you please. I don't think white-oak timber will give honey any bad taste. I have used it for 20 years or more, and have never heard any complaint. Ash timber is not fit for honey-packages. The honey will work through the grain of the timber. I have tried pine and basswood timber for honey packages, but I don't like either. There is nothing that suits me as well as good heavy white oak, with heavy iron hoops. I don't like the 60-lb. tin cans. I got ten pairs of them a few years ago, and have some of them yet. Two years ago I filled some of them with honey. They had to be filled full to hold the 60 pounds. Then I had some of them the next winter, and wanted to get the honey out. I put one at a time in a clothes-boiler over the stove, with water in the boiler to melt the honey. I took off the screw cap. The honey was candied. When it began to melt it began to run over. The hole was so small that I could not get any honey out except with a teaspoon—too much of a job. I would not put over 58 lbs. in them again. I like a good barrel with a few 50 and 100 lb. kegs, to retail. Barrels are easy to handle; you can roll them, and save lifting. I have shipped a great many tons of honey in barrels, and never had any leak. E. FRANCE.

Platteville, Wis., Feb. 4.

[I think I can agree with you, friend France, in regard to the inadvisability of merging the Bee-keepers' Union into the N. A. B. K. A. Under its present management, and with its small membership, the Union has done a magnificent service. Could it do better under the wings of the North American? I doubt it.

It is true, there is a kind of ignorant prejudice that some farmers and others have, that bees injure their apple-crops. At our Shane yard, located in an orchard, an old farmer intimated that, since the bees had been there, they had not been able to get any apples. I showed him that there were others who had no bees near them who got no better crops. The facts were, if the bees were removed entirely the crop would not be as good. It is a remarkable fact, that, whenever there is a good yield of buckwheat honey, there is always a good crop of grain. A poor yield of honey is accompanied by a moderate yield of grain. I am glad to get your testimony in regard to barrels. But I am of the opinion that, if you were in that dry climate of California for awhile, you would find it would shrink almost any thing; but your hints about having the barrels stored for six months in a dry place and then testing them with air instead of water are excellent.] E. R. R.

CONTRACTION.

THE RIGHT AND WRONG KIND.

Friend Root:—GLEANINGS for Feb. 1 has just come to hand; and while looking it over, I find some ideas near the top of page 88 that need answering, or a little explanation, from a contraction standpoint. It says, "The tendency of the times is against contraction to less than eight frames. It is far better to have a big, rousing colony on eight frames, than a medium one on four or six frames."

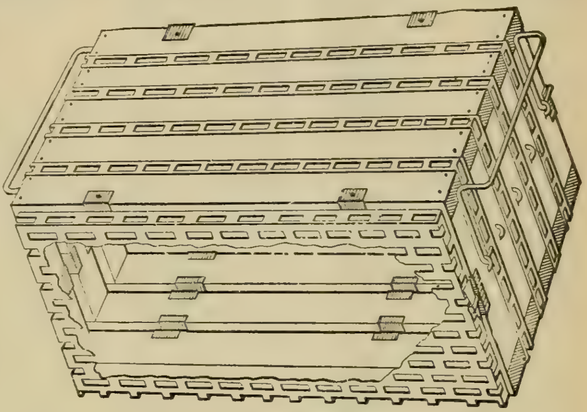
Now, suppose you have a colony and I have a colony, and the honey-harvest begins about the 25th of June and lasts until the 15th of July, you may give your colony the freedom of eight frames all the time, and I (in accordance with contraction methods) will give mine the freedom of eight frames all the time *until* June 15th or 20th, when I contract the brood-space to five frames. Would not my colony be as rousing as yours at the time of contraction? Would not my colony continue just as populous as yours for at least 21 days following the contraction?

I have not known a honey-harvest in the Northern States to last 30 days—scarcely 20; but even if the harvest lasted 30 days, the 9 days of brood production in the three questionable frames could not add to the storage of honey, because of lack of age of these bees.

I have often thought that the young bees that hatch from the five combs may be as sufficient to perform the labors within the hive as any larger number; or, in other words, they may be able to prepare the combs and store all the honey the force of outside workers may bring from the fields.

One of the principal aims of contraction is to get a rousing eight or ten frame colony, and then compel the bees to go into the sections. Contraction is really not much of a success until we get a "big rousing colony."

Now, I am a firm believer in contraction; still, I use a brood-chamber with four frames more than yours—that is, twelve frames. Up to swarming last year, I tried my best to have the queens fill all of the twelve frames with brood. Eight frames proved to be an average of the best they could do. At the opening of the honey-harvest I arranged queen-excluding zinc above and a queen-excluding zinc division-board on each side of the four center frames of brood, and placed the queen upon them. Then as there was no brood in the two frames that were in the remote ends of the hive, they were taken out and the two frames of brood on each side of the excluding division-boards were moved toward the ends of the hive, and a wide frame of sections sandwiched between them and the main brood-apartment. The sections were filled full of foundation. It required only about two days for these sections to be filled with combs ready for the honey. When the sections were half or two-thirds full of comb and honey they were taken from the wide frames and put in supers on the top of the hive, and new sections took their places in the wide frames. Twenty colonies were managed thus. At the close of a light harvest of seven days, each colony had a crate of 28 sections nearly finished, and five or six colonies had two crates each in similar condition.



DAYTON'S QUEEN-RESTRICTOR.

At the time this contraction was begun there was also put over each of sixteen picked colonies a rack of 28 sections, two or three of which sections contained combs as "baits." Of these sixteen colonies, only one went into the super to work foundation at all, and the rest came off as dry as when put on.

A bee-keeper, Mr. Guest by name, called a few minutes ago to talk bees, and said, "I think contraction must be what I lack. I worked ten days to make the bees go into the sections last year, and then failed."

At the top of page 88 it also says, "Pollen in the sections is usually the result of too much contraction of the brood-nest." It is because of a wrong kind, or of not enough contraction. Keep the queen upon four frames by zinc division-boards, then keep a brood-comb to catch pollen on each outside of the zinc division-boards, then put in wide frames of sections, and then frames of brood, and you will find the pollen near to the queen and the young brood.

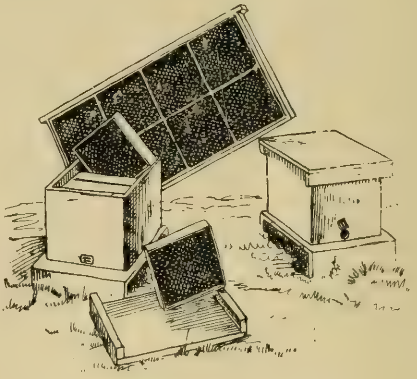
Clinton, Wis., Feb. 4. C. W. DAYTON.

[As you put it, and in your case, I do not know but I should have to make an exception; but for the average bee-keeper, I think that my remarks still hold true—that a big rousing colony on eight frames is far better than a medium one on from four to six frames; and after all, friend Dayton, it is considerable of an art to manage so as to make contraction a real benefit. If the season turns out just as we think it will, and if we have the requisite skill, all well and good; but too often contraction encourages swarming. Reducing the capacity of egg-laying, as a general thing, makes the bees dissatisfied. An unlimited capacity is quite apt to discourage, if not to prevent entirely, all swarming. Neither the Dadants nor Mr. E. France, who work on this latter principle, have swarming to any extent, and they do get the honey, you know. Now, it seems to me there is a happy medium between the two extremes—between the ten or twelve frame colony and the four or six frame colony; namely, the eight-frame hive. But you mention one advantage, and it is an important one too; namely, that by judicious contraction at the right time, and the use of perforated zinc, we may be able to get a large force of bees for the honey-flow, and yet very materially cut down *unnecessary* brood-rearing following the honey-flow. Your queen-restrictor will work nicely, no doubt; but is it not a great deal of work? Why wouldn't it be easier and less work to use shallow Heddon hives; and when you restrict egg-laying, do so by means of horizontal divisions rather than by perpendicular and horizontal divisions as you do? You are obliged to have zinc in between the end-bars of the wire frames and the top and bottom bar, as well as the two sides. You can contract by the Heddon plan by simply putting the perforated zinc board above and below one section, and the whole thing is done.] E. R.

RAMBLE NO. 38.

E. L. PRATT'S SYSTEM OF QUEEN-REARING.

Within a few years several young bee-keepers have come to the front, and, by their activity, are making quite a stir in the apicultural world; and although it has a shade of unpleasantness to us old duffers, we shall have, sooner or later, to take a back seat. Among this class of progressive young men is Mr. E. L. Pratt, recently of Marlboro, but who has now located at Beverly, Mass., less than two miles from Bro. Alley. Mr. Pratt is well known to the fraternity as the editor of the *Queen-Breeders' Journal*, which had a short but brilliant career. But Mr. Pratt's pen is not idle, as we often see his marks in the various journals. He has an apiary of 90 colonies, and will run them largely during the coming season in rearing yellow Carniolans. His system is much like Bro. Alley's, but his nucleus hive is constructed upon a different plan. The photo shows the hive and frame very plainly. The small frames are made by slitting in two a two-inch 4¼x4¼ section, and filled with comb cut from ordinary frames. The little hive contains four of these combs. Eight, as seen in the photo, will fit into an ordinary L. frame, thus enabling the combs to be changed from a nucleus to a full colony, which is a very good feature for rapid manipulation. The little frames, instead of hanging in the little hive, rest upon proper supports in the bottom. Perforated metal is used over every entrance, thus ensuring certainty of fertilization.



PRATT'S QUEEN-REARING HIVE.

At the close of the queen-rearing season, the little combs can be put into a large frame, and several be given to a full colony, with no detriment to the colony, but a kindness to the little pets that have been a profit to us during the beautiful summer days. Mr. Pratt has issued a neat little pamphlet describing his methods, which we judge he would be willing to send to those who wish to give his system a further study.

But train time drew near. Bro. Alley, Pratt, and the Rambler, arose from their very pleasant triangular talk, and Bro. A.'s horse hustled us over that half-mile at a lively gait. Our farewells were spoken, and with a final wave of the hand we were soon out of the pleasant village of Wenham, perhaps for ever; but we shall ever remember the pleasant hours we enjoyed in the famous Bay State Apiary.

THE WAY ALLEY GETS THERE.

As stated in our last ramble, our thoughts kept dwelling upon the subject of egg or larval queen-rearing, and our cogitations led us into the following review of the question. My first effort to get facts was to write to a large number of noted queen-breeders, from Maine to Texas, irrespective of race, sex, or previous condition. Answers were very courteously returned, and there was an almost unanimous answer for the rearing of queens from the egg, or, what is practically the same, just hatched larvæ. Only one raised a voice of disagreement, and claimed the 36-hour limit.

I therefore found that, as far as practice is concerned, the large majority were on or close to the egg plan; and the reason advocated was that the larvæ should early receive an abundance of food. The abundance of food is a very good thing to advocate; but upon this point I would give but very little for an opinion or an investigation that goes no further than the unaided eye can reach. Upon turning to our standard text-books I found this visible abundance prominently treated upon with more or less modifying points brought out by closer researches.

I also found two divergent lines of belief. The first class of writers would lead us to believe that especial royal jelly is given to larvæ designated to be queens from the very first moment of hatching. Class No. 2 advocates that all larvæ are fed alike until 36 hours old, and that a coarser food is given to the larvæ destined to become workers. As to which of these two classes is right, is, perhaps, beyond the reach of any one to definitely decide, until further researches are made; but we can quote opinions and tests as far as made, and find indications that point toward certain results.

When the investigator considers the wonderful changes that are effected, or, as Prof. Cook says, the "marvelous transformation—ovaries developed and filled with eggs; mouth organs; the wings; the legs; the sting—aye, even the size, form, and habits, all are marvelously changed," — that all this change has been wrought with merely an abundance of food, or a day's feeding, this, I say, is not a satisfactory explanation to him, and we find him studying the bee structurally, opening up to us a labyrinth of wonders which has been traced but a short distance toward its most intricate secrets.

Cheshire quite conclusively shows that larval food, or, at least, a portion of it, is a secretion from the lower or head gland, and that this food has the singular power of developing the generative faculty; but he is silent as to its chemical qualities.

We now turn to Cook, and find, on pages 89 and 117, Dr. A. de Planta quoted as showing from chemical tests that this royal jelly is different from the food of both the worker and drone larvæ.

If the royal food is different, as also hinted by other writers, when is it given to the larvæ? Doolittle, in class No. 2, says, after 36 hours; Cheshire, while substantially agreeing with this class, says, on page 289, Vol. 2, "The fact that queens are started from the egg in normal queen-cells is suggestive; but in addition it is noticeable that the amount of food given in the queen-cup exceeds that supplied to a worker, even in the initial steps." And on page 290, "The larvæ should be intended by the nurses for a queen from the beginning." Cook, A B C, and Alley, all stand in class No. 1, and would agree with the above quotation. I, however, find that Mr. Alley, who has been the most strenuous advocate of rearing queens from the egg, is tending toward class No. 2; for on page 171, last volume of the *Api.*, he says, "When eggs are placed in a queenless colony, the bees will not in all cases immediately commence to feed the larva for a queen." We also find Langstroth's Revised standing with class No. 2. As the case now stands, I find that class No. 1 are in the majority, both in theory and in practice; but I also find strong evidence that all classes are not satisfied with the investigations thus far, and would like still further light.

That good queens can be reared by both classes is a fact not to be controverted; and I think queen-breeders of every name and nature can show a long list of testimonials.

But the question ever recurs, Are we rearing the best type of queens? and if not, how shall we do it? The question can be answered only by a more searching investigation with the microscope than has heretofore ever been made. If we consult Cheshire we find the wonderful head gland No. 1, while fully developed in the worker, is only rudimentary, if at all, in the queen; but I quote: "It is peculiarly important to observe, that the higher the quality of the queen the further will she be removed from the worker in this matter—poor queens, hurriedly raised, really possessing this gland in an extremely rudimentary form, while those with the largest ovaries have even the plate imperforate, and no trace of a duct is discoverable." To the microscopist we must therefore turn for aid. If this duct is entirely absent in queens reared from larvæ 36 or 72 hours old, then they are good enough.

A series of close examinations would certainly teach us at what age to select larvæ for queen-rearing, which would be infinitely better than the present guesswork. Let us employ the microscopist. RAMBLER.

DOWN BRAKES!

L. C. AXTELL AGAIN ON CLOSED-END FRAMES.

Extremes exist in almost every thing, and I am not sure but we hear of as many who go to extremes in apiculture as in any other pursuit. I do not wish to belong to that class, and I really do not think I do. I notice in GLEANINGS that A. I. Root is whistling "down brakes" in regard to changing brood-frames; and from letters I have received relating to this topic since my article was printed in GLEANINGS on that subject, I am led to think he is right, and that there is danger that some may be led astray at the present time by what is said in the journals.

In the first place, I wish it clearly understood that I do not go back on what was said in my article on closed-end frames, and I firmly believe they have all the advantages claimed for them, and more might be said in their favor. Still, I do not think it would be wise for every person who keeps bees to drop every other frame. Those who are keeping but a few colonies of bees, as a general rule had better retain the frame they have in use, whether it be the closed-end or hanging frame, for the reason there would be so little difference in the amount of honey stored. Such as have the time, ample means, and a desire to experiment, let such test both kinds of frames, and give to others the result of their experience. But to all who are fully in the business as a pursuit, having *either style* of frame, and but one kind, I would say, *go slow in making any change*, at least until making a careful test. If only a part were changed, there would be the continual annoyance of two kinds—such an annoyance as I could not think of enduring. But in making an entire change in one or more large apiaries, it would involve a heavy expense. This, some could not meet without being involved in debt, while to others the loss in money would be more than all that ever would be gained in time saved or convenience.

Then, again, after using for years one method and one set of implements, even though the new were much superior, for a time at least they would be less wieldy and not satisfactory, and probably a wish many times that they had not made the change would be the result.

But to such as are beginners, and contemplate making bee-keeping a business pursuit, this point of closed-end brood-frames should, along with many other points pertaining to the pursuit, receive careful consideration and then be tested.

Nothing short of an actual test should satisfy. Obtaining the real hives with all that pertains to them, place them side by side in the apiary, put equally strong colonies in the different kinds; in this way, after a suitable length of time, each could decide for himself what would suit him best. No supplies for sale. I do not make hives, nor keep supplies for sale. Please do not send to me for hives or frames for patterns. L. C. Axtell.

Roseville, Warren Co., Ill., Feb. 12.

[I am glad of your caution. It seems to be a fact, that, when the merits of a new thing or an old thing revised are discussed, some one—yes, perhaps a good many, will rush headlong into it. I have suggested the wisdom several times of going slow. Some one will say, "Keep out the discussion altogether." That would not do. It is the business of bee-journals to bring up these things.] E. R.

[Permit me to add my most emphatic emphasis to the excellent points you make, friend A.] A. I. R.

GLOVES FOR BEE-KEEPERS.

MRS. HARRISON GIVES US SOME OF HER EXPERIENCE.

In Gleanings for Feb. 1, Emma Wilson requests those who have had experience with rubber gloves to tell how they like them. In the early days of my bee-keeping I asked a saleslady whom I knew, what kind of gloves they had, suitable for me to wear in an apiary. She placed before me a box of rubber gloves, saying, "Mrs. Harrison, this is exactly what you want—see how nicely they fit; just the thing for driving, and they will sweat your hands, removing all tan, and make them so soft and white." I paid the modest sum of $1.75, and went home rejoicing, and told the bees that I had gloves now that they could not sting through.

The weather was very warm, and I pulled on my gloves with a deal of pomp and ceremony, and went to work with the bees. In a short time I realized that I was very uncomfortable, and knew not why. I was very much interested in my work, and paid little attention to myself; and when I had finished I drew off the gloves and found them dripping wet. With a few times wearing they rotted out; and when I tried to mend them the stitches broke out; and ever since, when I see them advertised by supply-dealers, I feel like accusing them of fraud—they are a delusion and a snare.

I then procured the best-fitting pair of buckskin gloves, with gauntlets, that I could find, and sewed denim on them and an elastic, which keeps them in place, and bees from crawling inside. When these gloves get heavy with propolis I pick it off, which can be done easily with a little practice. When they wear through I mend them with soft leather cut from an old kid shoe. The wear all comes in the same place; and when the patches wear through, rip them off, pick off the propolis, mend up again, and they are good for another long season of wear. Whenever I work in the apiary without gloves I repent it; for if I am not stung, my hands are stuck up with propolis, and under and around my finger-nails; and using soap to remove it discolors my hands, and makes them rough and uncomfortable.

I had a friend who always wore linen mittens while working with bees, as bees do not sting through brown linen. I prefer gloves, and I would make them as a friend of mine did. She ripped up a pair of old gloves, for a pattern. Then she first cut out a pair from old muslin, sewed them up and tried them on. When she had them to fit exactly, she used them for a pattern and cut out a pair from brown linen. She wore them for driving; they could be washed and boiled; and as she had several pairs she always drove from home with clean ones. Mrs. L. Harrison.

Peoria, Ill., Feb. 4.

[O Mrs. H.! you have closed up your article, and did not tell us whether the rubber gloves took off all the tan or freckles, or not. How *could* you omit such an exceedingly important item? and who knows what a wonderful trade might have been worked up in rubber gloves if we could only have had a testimonial from you on this most exceedingly important point? May be I am mistaken, however, after all. Perhaps it was when I was a boy that our girls used to be so exceedingly afraid of tan or freckles. Well, I hope so. If you will refer to our price list you will see that we have continually, year after year, put in a protest. For some time I refused to offer them for sale at all, feeling so sure they were not needed. Notwithstanding this protest, however, there is quite a large business in rubber gloves, indicating that they are found valuable for at least some purposes. The driving gloves, I know from personal experience, are many times worth all they cost, where one is obliged to be out in cold wet storms; and since the matter has come up, I should be glad to have some brief testimonials from a great many, especially those who continue to use rubber gloves when handling bees. For keeping off propolis it occurs to me that cheap cotton gloves might answer, and perhaps they could be bought so cheaply that we can throw them away when they get badly soiled. If the quality will warrant, they might be washed in benzine and afterward in water, as you suggest in your closing paragraph. I never have bees sting my hands unless something obliges me to handle them at a time when they ought not to be handled.]

THE OHIO STATE BEE-KEEPERS' CONVENTION AT TOLEDO.

A FEW NOTES BY ERNEST.

Very unfortunately, my note-book gives only a few and scattering memoranda of the proceedings; and, moreover, our foreman of the printing department says I must be brief, as our space is all filled up already; and then he looked at the great pile of copy on the hook, not yet set up. Our friends of the convention will therefore please pardon me if it is short. I am compelled therefore to omit a good deal.

As soon as I arrived at the convention room I inquired whether Hutchinson and Hasty were present, and I was answered by being presented to the gentlemen in question. It was a rare pleasure to me to meet the one who had in years gone by made such beautiful translations of Virgil's treatise on bees, and one whose spicy writings never fail to give delight. As for Mr. Hutchinson, he is so full of enthusiasm and practical sense, that there were many things which I wished to talk to him about between sessions and at other times. He had betaken himself to an easy seat, and very evidently proposed to have a good time. At almost every convention he has ever attended, he has acted as reporter, but this time he proposed to be relieved.

These were not the only bee-keepers I hoped to meet; but they were the ones I feared might not be present, and whose presence we could not afford to lose. After we had had a pleasant little chat, Dr. Mason called the convention to order. We then listened to a spicily written paper by E. E. Hasty. I am unable to give the gist of it, because a summary would very inadequately give a glimpse of Hasty; but he showed very conclusively, from many instances, taken both from ancient and modern times, that honey is conducive to longevity.

In the afternoon we listened to an address by President Mason. After welcoming the bee-keepers to the city of Toledo he called attention to the fact that Ohio bee-keepers should take some action in reference to the Columbian Fair at Chicago. He alluded to the scheme that he had already made public, and published on page 58 of our issue for Jan. 15. He read a letter from J. W. Buchanan, chief of the Department of Agriculture at Chicago, in which the following questions were asked:

1. How many State associations will be represented?
2. To what extent will Canada be represented?
3. Should the entire exhibit in all its branches be installed in one department?
4. If so, how many square feet of space will be required?

To which Dr. Mason replied in substance, by number:

1. From 12 to 15; perhaps 20.
2. Largely.
3. Most certainly.
4. From 25,000 to 30,000 square feet.

A committee was appointed to investigate the matter, and make recommendations, and this committee reported, later, adopting the suggestions of the president, and recommended Miss Dema Bennett as State superintendent, under the advice of Dr. A. B. Mason.

A paper from Dr. C. C. Miller was next read, in regard to bee-laws. He called attention to the need of a few laws for bee-keepers, and referred to some that had already been enacted in Germany, in the interest of bee-keepers, and suggested the wisdom of our having something similar.

In the evening we listened to a paper on the subject of "How can honey-producers reach the trade? or, do we need a Union trade-mark?" by Miss Dema Bennett. The writer called attention to the importance of putting honey up in attractive packages, and exhibited some neat flint-glass screw-top jelly-cans. She did not recommend extracting honey from old combs, as it discolors the honey. Comb honey should be sorted in three lots. It should be appropriately labeled, and put in cartons. Put extracted up in tin pails. Every woman has a use for them. For groceries, a variety of glass packages should be used. Don't let glassed honey candy while on their hands, or somebody will call it castor oil; and don't allow the honey to get to leaking. Furnish grocerymen with photographs of your apiary, to show them that the product is produced honestly. As to a trade-mark, we do not need it. Some bee-keepers would abuse its use. She recommended an individual trade-mark. Mr. Hains uses some fancy printed cards, and on these cards is an engraving of his home apiary. Consumers always know that this honey is all O. K.

In convention, the discussion that followed showed that there was a dicided feeling against a Union trade-mark. It would be of no advantage to the honest bee-keeper, and might work injury to bee-keepers as a class.

J. B. Hains read an essay on spacing brood-frames, in relation to swarming. Mr. H. is the owner of from 500 to 600 colonies. He has them divided among some 13 different out-apiaries. His experience favored closer spacing. It resulted in more surplus honey and brood. Wide spacing gave more honey in the brood-nest, but very little in surplus.

THE ADVANTAGES OF USING FOUNDATION was the subject of a paper by W. Z. Hutchinson. It presented fairly both sides of the case, and certainly no one can say that Mr. H. was prejudiced in favor of the non or unlimited use of foundation. With foundation, he said we secure perfect combs; and if the securing of perfect combs is not the first and chief advantage, it is the next thing to it. If such combs could not be secured otherwise, it would pay to buy foundation at considerable expense rather than go without it. When he first wrote his little book he used empty frames of full Langstroth size in depth. The combs all grew at once, and he got good worker comb. In the Heddon hive, the plan does not work as well.

At the conclusion of the paper J. B. Hains and others insisted on full sheets of foundation for brood combs. Mr. Hasty argued for the non or limited use.

The subject of perforated zinc was discussed by volunteers. The opinion seemed to prevail that it was necessary in the production of extracted honey, and some even urged it for comb honey; and this brought up the subject of

BEE-ESCAPES.

Dr. Mason used the Dibbern style, and considered it a great boon to extracted-honey men. It did away with brushing combs, and made extracting much easier. In regard to perforated zinc, he must have it, because he did not want brood in the upper story. He wanted to have his extracting combs full.

In regard to wooden queen-excluding boards, Mr. Hutchinson remarked that he was probably the pioneer in their use. He said he had not discarded them because of the shrinkage of the wood, but because the bees would plug them full of wax. We was not of the opinion that those recently introduced by the G. B. Lewis Co. would prove to be a success, for that reason.

Near the close of the convention we listened to the report of the committee on statistics. It was ascertained that the average amount of honey secured by Ohio bee-keepers was 25 lbs. per colony.

Just before the close of the convention, J. Y. Detwiler, formerly of New Smyrna, Fla., begged leave to give the president of the convention a rough stick of black mangrove wood from Florida, and suggested that a good cane could be made of it. The remarkable thing about this wood was, that it was very heavy—so heavy, indeed, that it would not float on water. Mr. Detwiler requested that somebody be called upon to duly present the same to Dr. Mason. Some one called for Hasty. "What," said he, "right on the spot?" "Yes, yes," they said. Mr. Hasty stepped back, secured the cane, came forward, and then stood before the president. I wish I could give you his exact words, for he seemed to speak almost as if by inspiration, although it was evident that he had not had time for preparation. Said he, as nearly as I can recollect, "I hold in my hand, doctor, a piece of wood. Like yourself, it is a diamond in the rough. It can be made useful and ornamental. I see some blemishes in it. We all have our blemishes. I observe that it is very heavy—a quality that is indicative of its solidity of character, and a quality that is not altogether lacking in our president."

At the suggestion of Mr. Detwiler, that we take up a collection to finish up the cane, Mr. Hasty took out half a dollar, and several others did the same, and Mr. Eaton passed the hat to secure further collections.

Dr. Mason then responded in a very neat little speech. He had been president of a great many different organizations; he had been the executive for two years of the N. A. B. K. A., but no one thing had honored him more nor as much as this token of appreciation from the convention. He would receive the cane and remember it with thanks.

Those who attended the convention will remember this as one of the prettiest things that ever happened at any convention, and I regret exceedingly that no printed page can tell it as it really was.

The convention then adjourned to meet at Cincinnati. Charles F. Muth was elected president, and Mr. S. R. Morris, of Bloomingburg, O., secretary and treasurer.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

THE ARTIFICIAL-HONEY SWINDLE CROPPING OUT AGAIN.

I inclose an advertisement clipped from *The American Agent*, Dec., 1890, as I know your interest in protecting the welfare of our bee-keepers and honey-producers, and your activity in showing up such frauds as it tries to perpetrate upon the public. I should be glad to see your answer in GLEANINGS. W. BINGHAM.

Chapel Hill, N. C., Jan. 19.

Thank you, friend B. Here is the advertisement referred to:

HONEY.

I have a recipe for making honey equal to bee honey. I will send the recipe for one dollar by registered letter or money order. Big profits.

F. P. HARDING, Knightstown, Henry Co., Ind.

We hardly need tell the readers of GLEANINGS that the above is a swindle and a falsehood. Nobody ever yet succeeded in making an artificial honey equal to that made by bees, or any thing like it.

IMPORTANCE OF GRADING HONEY, AND WHEN TO DO IT.

Friend Root:—Always grade comb honey when you are cleaning up the sections for market, and never, under any consideration, put a section of second-grade in your case of gilt-edge. If you do, you will find, if you ship to the large cities and your salesman finds that one section, five times out of six your honey will be sold as second-grade, causing you a loss of about 3 cents per lb. I have seen large shipments of nice honey spoiled in this way by the packer saying to himself, "One or two bad sections in a case won't make any difference." But it often makes a difference on the wrong side of the ledger. As I said before, grade the gilt-edge all by itself and the second-grade the same, and third-grade all by itself, and then you can sell each grade by the case and get your price according to grade every time. I am pleased to see friend Ball's kind offer to friend Root in regard to the shipment of honey. Let us all say with friend Ball, "I shall be more careful about assorting and packing my honey after this." P. R. CYPHERT.

New Derry, Pa., Jan. 5.

[That is just it, exactly. On the principle that a little leaven leaveneth the whole lump, a little second-grade comb honey in a case (only one or two sections) oftentimes makes the whole case go for second-grade. It isn't fair, right, nor honest to mark a case "gilt-edge," or first-grade, and then slip in one or two second-grade combs. If the dealer discovers the second-grade sections in a first-grade case, he can hardly with fairness sell the whole case to his trade as first-grade, so he marks it second-grade, as he hasn't time to re-sort the honey.]

COMB HONEY ONLY IN SECTIONS; ALLEGED GLUCOSE HONEY.

I have been reading Mrs. L. C. Axtell's letter in Jan. 1 GLEANINGS, page 14. Toward the close she speaks of selling broken comb honey. Don't you think it a better plan to sell only honey in sections, or extracted? A lady friend was here visiting from Chicago. She said to me, "Don't let me forget to take back some of your comb honey." I said, "Can't you get it cheaper there?" She said, "Yes, but it was made stuff." The storekeeper she dealt with had it in pails, and she had bought it, and it would be a small piece of comb floating in syrup, sometimes of a different color than was in the comb, and she was sure it was adulterated.

Braceville, Ill., Jan. 5. MRS. BURR.

[Circumstances are such that a lot of broken comb honey is left in the hands of the bee-keeper. He and his family can't eat it all, and it's too good to feed to the bees. The groceryman can sell it for a little below the price of comb honey in sections. What's the harm of selling it in that way? I doubt whether the honey to which your friend refers was glucosed. It was probably pure honey. Did she have any other proof than that she guessed so?]

PAINTED MUSLIN IN PLACE OF TIN; OUTSIDE WINTER CASES, ETC.

As I stated in GLEANINGS last fall, I used a good stout manilla-paper cover well painted, and they so far have kept out all the rain, and, besides, are much warmer for the bees. So far my bees are packed with old newspapers and drop cover over hives. They are in fine condition—scarcely a dead bee. In fact, I think the packing superior to chaff; and it is cheap, which is an item to most of us bee-keepers, especially after so many poor seasons.

I see that E. T. Flanagan likes the Hoffman frame, only the cost is too great. This winter I have been making a closed-end frame which answers all purposes, and is remarkably cheap. I got good No. 1 pine lath, 1⅜ wide, and cut it into lengths in a miter-box for ends, using wire nails for the rabbet-rest. The frames are not so smooth and nice as you make, but they are good solid frames. One bundle of lath will make ends for 250 frames, or six bunches will make 1000 frames complete.

We have had continued cold weather since Dec. 1, and 48 days of sleighing—a real old-fashioned winter. T. G. ASHMEAD.

Williamson, N. Y., Jan. 18.

[Friend A., we are well aware that paper, cloth, and a good many other substances, when painted, will answer very well; but when it comes to handling hives, drawing them on wagons, etc., they are so apt to be torn and injured that I think most will agree that it is better to pay a few cents more, and use tin. I told Ernest, when he mentioned it, that the idea was once considerably used, and afterward abandoned, years ago.]

KIND WORDS FROM A COLORED BEE-KEEPER.

Mr. Root:—I never see or hear of any colored folks who have a little home and keep bees. I have 17 stands in the Simplicity hive. I like to hear my gal read your bee-paper. I don't subscribe for it. A bee-keeper that has a big apiary loans his paper, and tells me how to get the most honey; hives four-story; no swarm.

I love to hear Jane read about Home and Our Neighbors. One white man says, "Mr. Root got no use for a negro; don't believe he will take any notice of a letter from one."

Whistler, Ala. Doc Singleton.

[Friend S., your friend is very greatly mistaken in saying that I have no use for letters from our "colored friends." On the contrary, I have been more pleased to get your letter and kind words than any others that I often get hold of. May God bless you and your people in bee culture, in getting an education, and in learning to take care of yourselves. We give the letter just as it was received.]

OUR QUESTION-BOX,

With Replies from our best Authorities on Bees.

Question 179. *Are bees which have been wintered in the cellar as hardy as those wintered outdoors?*

I think so.
Louisiana. E. C. P. L. Viallon.

I think not.
Illinois. N. C. J. A. Green.

Yes, if well wintered.
Wisconsin. S. W. S. I. Freeborn.

From all that I can ever see, they are.
California. S. R. Wilkin.

I know of no reason why they should not be.
Ohio. N. W. H. R. Boardman.

I doubt it very much. They are certainly more subject to spring dwindling.
Ohio. S. W. C. F. Muth.

I do not know; do you? So far as I can see, they are.
New York. C. G. M. Doolittle.

Yes, sir; the bees are just as hardy. Cellar-wintered bees may have more brood than they can take care of after being set out.
Michigan. S. W. James Heddon.

They say not. The few I have had in the cellar seemed to compare favorably with those wintered out.
Ohio. N. W. E. E. Hasty.

I think not; but if properly wintered and cared for in the spring, they will do as well, and frequently better, than those wintered outdoors.
Ohio. N. W. A. B. Mason.

I think so, if wintered as well. When they seem weak, something was wrong with the cellar, the food, or the bees.
Michigan. C. A. J. Cook.

Hardly; yet there are plenty of seasons when they fare just as well as those wintered out of doors, but we occasionally see a season when a number of bees die shortly after being taken out of the cellar.
Illinois. N. W. Dadant & Son.

Those that winter both ways the same winter can tell better than I. But from what I hear from others, those bees wintered in cellars are more liable to dwindle in spring.
Wisconsin. S. W. E. France.

Hardier, provided they have wintered better; less hardy, provided it is the opposite. The constitution of the bee will stand a certain quantity of hardship; and when that has been endured, it dies.
New York. C. P. H. Elwood.

Yes, though I once thought differently; but if put into outer cases when taken out of the cellar, they seem to do as well as those wintered out. Hence, wintering in the cellar does not seem to weaken their constitution, when treated the same as those wintered out.
Vermont. N. W. A. E. Manum.

Bees set out of the cellar in March may not be; but keep them in until warm weather comes to stay. One year a freeze came April 5th, and killed outright a pear-tree in bloom, and many colonies. Those in the cellar, put out afterward, were stronger than those wintered upon their summer stands.
Illinois. N. W. C. Mrs. L. Harrison.

I don't know. I don't know any reason why not, if the air is good in the cellar. Indeed, if the air is as good—but that "if"—I see no reason why they should not be a little hardier in the cellar, for endurance of too much cold enfeebles. Still, I have an uncomfortable suspicion that, for some reason, outdoors may be hardier.
Illinois. N. C. C. Miller.

I understand from the question, "Are bees as hardy to withstand spring changes?" I think, after wintering in a cellar with a temperature of 50°, and placing them upon the summer stand before settled weather, the bees will not withstand changes so successfully as those wintered outdoors. The secret is, to hold them in until there is but little danger from those changes. Chaff hives might enable them to get along successfully, but I have but little faith in that plan.
New York. E. Rambler.

[Well, for once we have got a question where there is *not* unanimity. It starts out, "I think so," and then, "I think not," and so on. Then it becomes apparent that locality has something to do with it. Our good friend Muth, away down in Cincinnati, prefers his bees outdoors. Doolittle thinks that, where he is, one is as good as the other. Prof. Cook agrees. Friend France, with his great big tenement hives, as I should suspect, prefers outdoor wintering. So you see it depends on the size and kind of hive. And then friend Manum suggests that, when taken out of the cellar, they should have outside protection. And, by the way, some good friend declares that the best way in the world to winter bees is to put them in chaff hives, and then carry the chaff hives into the cellar. When you carry them out in the spring they will have the chaff-hive protection. Mrs. Harrison says it depends on how late you leave them in the cellar. Taking a thin-walled hive right out of the cellar, and leaving it exposed to heavy frosts or severe freezing, is not just the thing. Dr. Miller has an uncomfortable suspicion. If he were in our locality, I think this "suspicion" would be still more uncomfortable. Rambler winds up as if he had heard what all those have said that go before him. Friend R., it must be on account of so much "rambling" that you have gathered up so much wisdom. You know about the rolling stone. Well, if you did *not* get the "moss," probably the *wisdom* is worth about as much.]

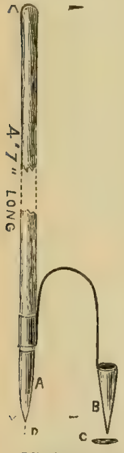
SPECIAL DEPARTMENT FOR A. I. ROOT, AND HIS FRIENDS WHO LOVE TO RAISE CROPS.

Our friends will notice that the gardening department is very much larger for this issue. Well, it came about in this way: Some of our older readers will remember that I have always been in the habit of becoming especially talkative in the month of February. Another thing, quite a lot of queries for this department have been accumulating under a special weight of mine; and to give us room, the printers have kindly put in eight extra pages for this issue. If there is any thing in any of my talks that you do not care to read about, you can just skip past it and take the regular GLEANINGS matter.

THE NEW METHOD OF RAISING ONIONS.

The principal expense of this new method of raising onions is the labor of transplanting. I quote the following from the new book on onion culture:

> To plant one acre, we have to set 130,000 plants, as already stated. I can get boys, that, with some practice, will set from 2000 to 3000 plants a day, and nimble-fingered persons, used to garden work, will easily set 4000. The job of planting an acre is therefore equivalent to probably not less than 30 or 40 days' work, and in some cases this estimate may be considerably exceeded, but the amount of $50.00 should be more than enough to pay for the whole job.



DIBBLE WITH SPACER.

Now, when I read the above it occurred to me that it did not cost us much more than *half* the above amount, and perhaps our appliances have something to do with it. For some years we have used a tool for making the holes, which is really a long-handled dibble. Whenever a high-tempered hoe snaps off from the handle, we take the handle and shank and grind the latter down to a sharp point. This makes a dibble like the one shown in the cut. Well, although a *man* would space the holes very well by his eye, our small *boys* could not well be intrusted with this work, even if they wanted to do it ever so bad. They would get some of the holes two inches apart, and some six inches; therefore I devised the spacer shown in the cut.

A is the dibble, made of a hoe-handle. The point, being steel, is kept free from rust, and will readily free itself from dirt, providing the operator rolls it in his hand before he undertakes to withdraw it from the earth. This will be very quickly learned after a few trials. D is a hollow point made of galvanized iron. It is attached to a loose ferule encircling A by a stout bent wire. By bending this wire you can make the holes as far apart or as near together as you choose. The point B goes a little below the point A. Let C represent a hole in the ground, which is made with A. Now our boy sets B in this hole. This lets A drop down through the ferule; and by giving it a slight roll as it comes out, it leaves a hole like C, and lifts out B. Then he can go on almost as fast as he can walk, and have the holes as accurate as if made by machinery. Every little while somebody suggests a wheel with cones on the tire, so as to prick holes as the wheel rolls over. I have such a wheel that cost me several dollars. Of course, it will make marks in good soil plain enough to show you where the holes come; but it does not make a good hole to take a plant. Another objection is, that it makes so much travel over the ground. When our ground is in nice condition, we do not want it stamped down by boys and men running over it a great number of times. The implement shown in the cut suits me best. Three boys will plant onions with a rapidity that will surprise you, and do it so well that every onion will grow, even if some of the boys *are* quite small. One goes along and pricks the holes. Another carries the basket and drops the onions, taken from the greenhouse, one in each hole. The last one straddles the row, going along on his knees, and firms the dirt about each onion. As soon as they get through, I would run the wheel-hoe or rake through the rows to mellow up the ground where they have stamped it with their feet and knees. After that, the wheel-hoe will do all the work, or nearly all, until your crop is ready to gather. The onions are so much ahead of the weeds that the weeds seem to be discouraged, and evidently think it is not worth while to try to overtake them.

FIXING THE BOUNDARIES OF YOUR PREMISES.

In these modern days of no fences, it becomes desirable, many times, to know just where the line runs between your neighbor and yourself. Without fences, you know we can have growing crops clear up to the line or on the line; and as we expect to work our land by horse power, of course, not only is any sort of fence an obstruction in the way of cultivating, but even a stake gets in the way, or is knocked down, etc., unless, indeed, we put in a great heavy post. But this is expensive, and is in the way, besides. Now, I will tell you what our men are putting down for corners and boundary landmarks around my high-priced lot across the way. We had some rustless iron gas-pipe, an inch in diameter, that had burst by freezing. I know we were very foolish to let it freeze and burst; but as soon as it happened I began to wonder whether it could be utilized in some way so as to be worth almost as much as it was before. Well, we cut it up into lengths of 2 and 3 feet. Then we united the 2-foot pieces to a 3-foot piece by means of an ordinary coupling. On all of our corners a 3-foot piece was driven into the ground just level with the surface. Then a 2-foot piece was screwed into it by hand. Now, in plowing or cultivating, the 2-foot piece can be screwed out until the horses are out of the way. Then take a spade and find the lower part, then screw in the 2-foot piece again. On our east boundary, along by the railway, we have put one of these iron posts every 50 feet. A 2-foot piece of poultry-netting can be run on these pieces, if need be, and this will make a sufficient barricade to protect the crops to some extent; and yet when it comes in the way of cultivating, just slip the poultry-netting off the posts, and lay it back out of the way. How many times does a surveyor have to be summoned, and expensive surveys made, to find the corner of a lot! A piece of rustless or galvanized iron tubing driven into the ground three feet will make a landmark that will stand for hundreds of years; and with this 2-foot piece screwed into the tube it can be easily found at any time. If somebody should drive over it and break it off, it would probably result only in splitting the coupling, and a new coupling could be purchased for three or four cents. In view of the many troubles and quarrels that have resulted in regard to boundary lines, will it not pay you, my friend, to put down such a landmark on every corner of your premises? Even after the surveys are made, as surveyers do not all do their work just alike, a corner is apt to be located at a different spot (unless very plainly marked) from where it was originally. This leaves the way open for still another survey at some future time, and, may be, a quarrel.

THE EARLY PIE PUMPKINS.

Friend Root:—I don't think you half appreciate the good points of the early pumpkins. You speak of their being early, but they will keep late too. We kept some until Feb. 1 this winter. The best thing about them is their fine grain, some of them equaling the Hubbard squash in sweetness and texture. They will cook as quick too. Our folks cooked some once, and made pies and got them in the oven before breakfast. Compared with the old kind that have to be cooked half a day to get the water out, this is a great advantage. Although small there are nearly as many pies in each one, because you don't have to cook away so much water, and there are more on each vine. I got over 100 from about a quarter of a five-cent package of seed bought of you. They make the most delicious pies that I ever tasted; but there is just one trouble about them, *they won't keep!* I wish some one would tell how to can them. We have tried many times, but so far have always failed. It can be done, I know, for the canning factories do it. CHALON FOWLS.

Oberlin, O., Feb. 21.

FLORIDA GARDENING.

Our gardens nearly all have cabbages here. We have plenty of new cabbages now, and will begin to ship some about the first of February, if the market is favorable then. We can keep our cabbages several weeks after they head up by taking a plow and tumbling them out just so as to stop the growth; and it will harden the heads, making them heavier; or if they are uneven in heading, we go along the row with a long-handled spade and turn partly out of root the overheaded by putting the spade down near the stalk, and prying it over. In doing this, always turn to the north, so the sun will not burn the heads. Radish, turnip, and onions, are on our bill of fare. Peas, beans, and potatoes, will be along soon. I could tell you several other things that might not be new to you, but still are worth thinking over, when we have time to reason with nature and her laws and products.

THE IMPORTANCE OF GETTING GOOD CABBAGE SEED.

I read in GLEANINGS about Mr. Passage having trouble with his pumpkins. Well, we are having far greater trouble with our cabbages. In the Early Summer (Henderson's), in my field of three acres, beginning to head, I can show all kinds named, all from the same package of seeds. The greater *part* are true Early Summer, but there are many like the Wakefield and York varieties, and some like the tall Drumheads. My seed came from James J. H. Gregory. I have some of his *All Seasons.* They show very little of the sport; but my neighbor's fields near me (who used the Early Summer, from Peter Henderson & Co.), show a great many varieties, or types, of them, or sports. This "*sporting*" is *very costly* to us, for many of the sports will not head up to be of any use, for some of them will be several weeks later; and, besides, there are only a very few kinds of cabbage that will head up solid here. I call this sporting "hybrids," or crosses of various kinds. Could not our seed-growers grow their seed isolated, so there would be no hybrids? J. CRAYCRAFT.

Astor Park, Fla., Jan. 27.

[Friend C., we have much the same trouble (with the best cabbage seed we can get) here in our locality. I think, however, that raised by our good bee-friend H. A. March has less of this sporting. Have you ever tried his Jersey Wakefield and Fottler's Brunswick? A couple of years ago we had some choice seed sent us from Holland, that I believe gave a greater number of uniform heads of late cabbage than any thing else we have ever grown. With the wet seasons we have had, however, for two or three years back, I believe we have had *more* trouble from heads bursting than from sporting. Of course, we cut off the roots with the spade, and "unscrewed" them in the ground, so as to snap off most of the roots. In some cases we treated them so severely they began to wilt; but with plenty of rain they started out new roots, and in a week or two began to burst again. If there is a strain of cabbage in the world that will neither burst nor throw out sports, such as you describe, I presume we could pay a *dollar an ounce* for it, and make money then.]

RAISING STRAWBERRY-PLANTS FROM CUTTINGS.

The strawberry may be increased very rapidly by buds or cuttings, and this is the way I do it: Frames, nearly four feet wide, and any length desired, are made of common fence-boards six inches wide. The soil within them is made fine and level. Of course, it is rich. The surface is then covered about half an inch deep with sand, and moderately watered. Screens are needed, and I provide them by making lath frames, three feet by four, and covering them with new cotton cloth, fastened on with carpet-tacks. We are now ready for the cuttings. The best time to take them from the beds is when the dew is on; but if it can not be done then, it may be done at any time in the day by putting them into a pail of water as they are cut. They are at the right stage when the roots are just starting. If too young, failure will result; if too old, the roots are in the way. Sometimes a runner is prevented from rooting until it has several leaves, and in such a case all but one must be removed. In trimming, the runner is cut off within two inches of the bud, or embryo plant, and the cutting is thrown into water. This work must be done in the shade. It is not best to trim too many at a time. If they remain in water over night they are apt to fail to grow. When ready to put them in the frame, place a lath, or other straight-edge, across the bed, on the surface, and run a thick knife along the side of it, making a straight cut, perhaps three inches deep. The cuttings are thrust into this cut until the points from which the roots start are half an inch below the surface of the sand. The cuts should be four inches apart. The soil should be damp, but not wet enough to be puddled. If the work is done when the sun is shining, it is well to water the cuttings as fast as the rows are finished, and cover at once with screens. They must not wilt. They should be set two or three inches apart, according to the purpose for which they are being rooted. If they are to remain in the frame until sold, a month later, they need more room; if they are to be taken out and potted in a week, less will answer.

The frames need careful watching for a few days. The shades are to be removed in the afternoon as soon as the sun ceases to shine on the beds, and replaced in the morning before the dew is all dried off. It is usually well to give a moderate watering when the screens are taken off, and again before they are put on. If very hot and dry, it is a good plan to spray or sprinkle the screens two or three times during the middle of the day. If damp and cloudy, they may be left off all day. As the roots grow deeper the tops can bear more sunshine, and in a few days they will need shading only in the middle of the day. Plants rooted in this manner usually have longer roots, but fewer of them, than those grown in the natural way, and they bear transplanting much better, having been thrown upon their own resources when very young.

Some one may wish to ask what is to be done with the cuttings that have roots when they are taken from the original bed. Treat them as cuttings, if the roots are less than an inch long, although, as before stated, they are not as good as those taken off at the right stage. If the roots are an inch long or more, treat them as plants, heeling them in by themselves in the frame, and shading and watering judiciously until they are able to take care of themselves.

The method herein described has some advantages when used with care and judgment. It enables those who sell plants in summer to save the young plants and runners which would otherwise go to waste. It enables market gardeners to have a large number of good, uniform plants that can be taken up rapidly and set where some early crop has been harvested, thus making the strawberry a catch crop. It enables horticulturists at experiment stations and elsewhere to have a large number of varieties ready for planting at the same time, and all of the same age. Sometimes we want to plow a bed as soon as the fruit is gathered, and by this method we can save the plants.

Cuyahoga Falls, O., Feb. 4. M. CRAWFORD.

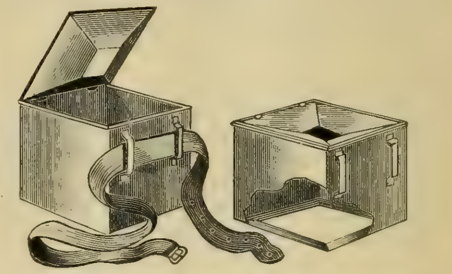
FORCING RHUBARB IN WINTER.

We are just now getting 15 cts. a pound for rhubarb for pies. I presume the scarcity of fruit explains why people are so willing to pay so much more than usual. By the way, we have learned a trick in forcing rhubarb. If there is any place in your greenhouse that is *too hot* for any thing else, it will be just right for your rhubarb-plants. Set the roots in very rich soil, and then cover them up with manure, either new or old—it does not seem to make much difference. Keep them constantly wet, and they will make the most astonishing growth of any kind of vegetation that has ever come under my observation. Another thing, it does not make any difference how dark it is. They will grow just as well in the dark as in the light, and you can plant them right up close to the boiler, furnace, or flues. The principal item is to get great strong roots grown in the open air, for forcing purposes. We have been buying them for about $2.50 per 100 roots. The roots are of such size that 100 just fill a barrel. If somebody has some large roots for sale, I think they would find it profitable to advertise them. It will be quite a little time before strawberries come, and there is going to be a great call for "pie timber" meanwhile. Whenever the ground thaws so you can dig the roots out, just put some in your hot-beds, or, later, in simple cold-frames. Give them manure enough, and see what great stalks you get. If the demand is going to increase for these roots, it may be well to think about sowing seeds pretty soon, so as to have the roots in readiness for another winter.

AIDS TO BERRY-PICKERS.

Although it is quite a little time before berry-picking comes again, it may be well to consider, during these winter months, appliances that may help us to rush things when the season comes round. The one illustrated below was engraved from a machine which I saw at friend France's, in Platteville, Wis. It is especially designed for blackberries, but it may be used for raspberries, currants, and other like fruits. The cut below almost explains itself.

The apparatus is made of tin, just large enough for a berry-box to sit inside. It is held around the waist by means of a belt. A hopper-shaped cover deposits all the berries in the center of the basket; and when they come up so as to strike the mouth of the hopper, the picker has notice that his berry-box is exactly full, with the top nicely rounded up. In our berry-picking, where they pick by the quart, there is always more or less discussion as to how full the boxes should be. Some of the little girls would heap them up so there was a fourth more than good measure; and I am sorry to say that some of the boys brought them in scarcely level full. The consequence was, the boss had to take some from the boxes picked by the little girls and fill out those brought in by the selfish and greedy boys. Boys, aren't you ashamed of yourselves to be outdone in honesty and liberality and fairness by the little girls? Well, this machine fixes the whole matter as to how full the box should be. But, most important of all, it enables the picker to use *both* hands; and with *blackberry*-bushes this is most important. Friend France says, as soon as he fitted out his berry-pickers with these machines they picked berries so much faster, that, when they came in at noon, they volunteered to drop a cent a quart on the price he had been paying them, if they could all have the picking-machines. Now, I tell you this is a pretty big testimony in favor of any implement to lessen hand labor. The bottom to the tin box is just large enough to hold the box securely. As I find the same device figured and described in our gardening periodicals, I presume such arrangements are not exactly new. The one given above, however, seems to be the most practical.



MACHINE FOR PICKING BLACKBERRIES.

A TREATISE ON TOMATO CULTURE.

The above is the title of a little pamphlet just out, by J. W. Day, of Crystal Springs, Miss. There are three things that make this little work of special interest to me. First, it is the only book I ever saw or heard of, devoted entirely to tomato-growing; and you know I am greatly interested in any thing in regard to special rural industries. Second, it comes from the South. Our Southern friends have, as a rule, been a little behind in books on horticulture, gardening, etc. Third, the book was written by a live, practical man. Let me make a little extract from a private letter:

> I have raised hundreds of acres of tomatoes, and I shall put out 100 acres this season. I am a subscriber of GLEANINGS, and like to hear you speak of your berry-raising, gardening, etc. We grow large fields of strawberries, and have a little over 400 acres in peach-trees in this place alone, besides some at other places. I am a partner of Parker Earle at this place.

Our readers will remember Parker Earle as the introducer of one of our most promising strawberries from which it takes its name. Even in Mississippi it seems they need hot-beds to start the tomatoes. The little book gives directions for making two kinds—one with a furnace with a long flue through the center of the bed, and the other made of stable manure.

These directions are exceedingly practical. At the outset one almost begins to wonder what varieties would be recommended by a grower who raises tomatoes by the hundreds of acres, and I think we will copy what the author has to say in the matter:

VARIETIES.	Size.	Color.	Flavor.	Smoothness.	Earliness.	Prolificness.	Hardiness.	Total.
Acme	10	10	10	10	10	7	7	62
Essex Hybrid	10	10	8	10	7	10	7	62
Livingston's Beauty	8	10	10	10	10	5	5	58
Turner's Hybrid	10	10	7	7	7	8	8	57
Buist's Beauty	10	5	5	8	8	10	8	54
Buist's Prize Bell	10	5	5	8	7	10	8	53
Livingston's Favorite	8	5	5	8	8	10	8	52

It seems from the above, that friend Day places the Acme ahead of all others, all things considered. I wish he would tell us whether he has ever tested the Ignotum—probably not.

The directions for sowing the seed are exceedingly interesting, and I was specially pleased to see that the author recommends using largely what he calls bat guano. When I visited Mammoth Cave I was greatly exercised because the great heaps of excrement, from the bats that clung to the walls, lay there on the ground unused, perhaps the accumulations not only of centuries, but may be *thousands of years*. Who knows to the contrary? I questioned the guide until he became weary of the subject, I thought, and I have since been told that this bat guano has been found in immense quantities in many caves in the South. Why should we go to the remote islands of the sea when these deposits lie safely housed from the rain in the caves throughout our land? I wonder if the readers of Gleanings can tell me more about bat guano. Then friend Day tells us about cold-frames for the plants, made of a covering of cloth, to be rolled up on a long roller. He says that one man, by going to the middle of the bed, can roll a curtain 200 feet long. Well, I have used these beds covered with cotton cloth rolled up on a roller; but, my good friend Day, what do you do when there comes a tremendous wind, and just flops your cotton, roller and all, all to bits? It is true you might roll it up, but then what happens to your plants? Then suppose the hard wind is accompanied with snow and rain. In your locality it will very likely answer very much better. In transplanting and moving plants to the field, there are a hundred little hints that none but a practical, hard-working man would ever get hold of. I have had just about experience enough to appreciate most thoroughly the short cuts that save labor and backache, given in this book. His directions in regard to transplanting to the field give us such a vivid picture of real life in market-gardening that I want to give it right here:

TRANSPLANTING TO THE FIELD.

> If you have a large crop and not much force, begin a week ahead, and have every thing possible ready and at hand—water at hand in barrels, hoes and spades and trowels and hand-bearers; and every thing that is to be used in getting the field ready must be ready, as a day at this time counts five days at any other time. Experience will teach you this. A little illustration will suffice here: On the 3d of April, 1884, I prepared land until nearly night, and it began to look like rain. We set a few hundred that evening. It rained that night, and continued ten days, and the plants in frames grew two feet high, and fell flat, and were almost worthless; while the few hundred I set that evening surely bore the finest crop I ever saw.
>
> The inexperienced will ask, "Why didn't you set all day and the day before?" Frost! frost! is why; but as the 5th day of April is the limit of the frost season here, we begin to plant just as soon in April as the first frost passes, which is between the 1st and 5th. I am aware I am digressing a little; but to the inexperienced, for whom this pamphlet is written, it will all come in good.

There is a chapter on trellising, or staking, and this seems to us a very important item. The author says, if we want extra early tomatoes we must prune and stake them. If we want a great lot of tomatoes, and don't care about having them particularly early, give them more room and let them sprawl over the ground. By pruning and staking them he gets them as close as 18 inches; but where they are allowed to grow according to nature, put them twice as far apart each way.

Now, I have said so many encouraging things about the book, perhaps I should speak of some of the discouraging features, even if I do hate to do it. The price of the book is 25 cents for only 25 pages of matter, and many of the pages are not half filled at that. In view of the great value to be found in the book, we might overlook this if the grammar, punctuation, and spelling, were not so exceedingly faulty. But there is still another greater lack. The book is not illustrated at all, when it should have at least one nice picture on every page. I have advised the author to sell this edition at a low price, and get out a finer one, for there is certainly abundant need of a nice little book on growing tomatoes. I am so sure he will agree with me that I shall take the liberty of offering the readers of Gleanings the little book for 20 cents, postpaid.

PETER HENDERSON.

From a memoir entitled, "Peter Henderson, Gardener, Author, and Merchant," written by his son, Alfred Henderson, I extract the following from the remarks of a great and good man, and one who has certainly been a benefactor, not only to our nation, but to the world, in the line of gardening and horticulture. The first extract is taken from a magazine printed in 1866, when they were discussing horticultural patents:

> I consider that man particularly unfortunate who asks a patent for what he thinks to be a discovery in horticulture, for there is a free masonry about the craft which begets a generous exchange of information; and he that holds a "secret" to himself, or intrenches his "discovery" behind a patent-right, is not usually benefited thereby.

Right in keeping with the above comes the following:

> His thirst for knowledge was so strong, that, in his first apprentice days, his companions in the "Bothy" used to laugh at him for reading the dictionary at his meals. He kept at it for six months until he finished it, and then pronounced it a most interesting book, "no matter what others might say." The practical outcome of it was, that his "Bothy" companions found that, when he was through, he could spell and define any word which they might put to him. But, with all his studiousness and industry, he was not a recluse by any means, for there is ample testimony to show that, in all the frolics of the country side, he was always the leading spirit.

And again on page 37:

> Mr. Henderson was not only an abstainer from liquor, but tobacco in any form he never touched. He was very regular in his habits, and simple in his tastes. Up to the close of his life he made it a rule to spend from three to four hours every day in the open air.

Now, boys, I tell you there is a big sermon in just the above extracts I have given you. As the twig is bent, the tree is inclined. The memoir I have alluded to is a little book of 48 pages, containing a steel-plate engraving of Peter himself. I do not suppose the book is for sale, but very likely the friends of our departed leader in the gardening business can have one on application.

MYSELF AND MY NEIGHBORS.

Resist the Devil, and he will flee from you.—JAMES 4:7.

If the great Father above has given me any particular message to deliver to the children of men, it is along the line of our text. I see people all around me struggling against evil—not the same sort of evil, by any means, for the thing that tempts one has no attraction at all for another; and Satan's ways of working are so diverse and so many, that sometimes I think it is only once in a while that we find two people who are tempted precisely alike. A few days ago Huber came home from school, with a remark something like this:

"I tell you, pa, Miss Smith is having almost as much trouble with the boys in the new schoolhouse as you are with tobacco among the factory hands."

"Why, you don't mean, Huber, that the boys that go to the new schoolhouse—the little ones —are using *tobacco?*"

"No, they don't use tobacco; but the trouble she has is because she can not get them to stop using bad and naughty words."

You may be sure that my heart went out in sympathy for my excellent, hard-working friend who is principal of the four juvenile classes in our new schoolhouse. After prayer-meeting was over one evening, I mentioned to Miss S. the report Huber had given.

"Well, Mr. Root, I am very much obliged to Huber for his sympathy, if for nothing more. We four teachers have been having a real time with this matter of profanity and obscenity; and it has obtained so persistent a hold among some of even the very small boys, that we are almost at our wits' end. I do wish you would come down and see if *your* influence in addition to ours may not amount to something."

Not very long after this, a little note informed me that they would be very glad to see me at three o'clock that afternoon. I went, and was ushered into one of the rooms, for school was just closed, and pretty soon eight small boys came in slowly, with downcast eyes and sad countenances, evidently expecting punishment or a severe reprimand which they evidently felt they deserved. Miss S. remarked that these were the ones who seemed to do no better, even after they had been repeatedly admonished. For a little time all was silence. I motioned them to take seats, and I sat down as near as I could well get to them. As I looked into their faces I inwardly prayed for wisdom to get a real strong hold on those little hearts—yes, even though Satan had already made sad inroads therein. I remembered my hobby about getting acquainted, and in fifteen or twenty minutes I felt happy to see them not only listening to all I had to say; but before I got through, they asked *me* questions, a great many of them. My prayer had been answered. They looked up with fear when I first came in, but we were now all on very friendly terms. They had given me a promise to try harder to resist evil: and when I told them that God heard that promise, and asked them to kneel down while I prayed that he would help them to keep it, every boy knelt down by me; and during my brief prayer you could have heard a pin drop. Their ages ran from seven to twelve. The youngest said, in our confidential talks about the matter, "Mr. Root, I can keep the bad words back without much trouble unless something gets me real mad, and then I can't help it. They will come." May God bless and help this poor child of seven! I told him that great big men had exactly the same experience he had, and that some of them, with all their strength of mind and muscle, did not succeed much better than he did. They told me, too, about big men who set a bad example, and, without knowing it, perhaps taught them these bad words. I promised them that I would talk to the big men too, and I have commenced it. I exhorted them, in the language of our text, to keep these words back, and hold them in with all their might. I explained to them, that, although it is bad and wicked, even to think "swear words," it was a hundred times better to keep them back and not let them out; and I told them that, if they kept them back resolutely, by trying real hard, by and by the bad thoughts would step out, and I unconsciously preached a sermon for myself at the same time. Resist the Devil, and he will flee from you, my good friend. I asked the boys about their mothers; and, oh how I do wish I could see these mothers, and have just such a little talk with them! I would admonish them to whisper a kind helpful word in the ear of these precious boys of theirs, just as they start for school; and then I would exhort the mothers to be on the watch when school is out; catch the anxious, restless chap in your arms for just a minute, and ask him if he has kept the promise that he gave you in the morning, to refrain from bad words. Oh! if you will do this, dear sister, the schoolteacher will not feel her labors are like casting pearls before swine. I know of a mother who fought Satan long and faithfully, right along on this line; and, with God's help, she triumphed. Her boy is now superintendent of a Sunday-school, and doing what he can for a great lot of just such urchins as he was a few years ago. After the boys had gone I asked to see all the teachers. I sat down with them and exhorted them to be not weary in well doing. In speaking of the parents, Miss S. told me that she sent a note home by one of these same boys —the oldest one in the lot, in fact—a note to his mother. Shall I tell you what the mother did? She gave the boy a tremendous whipping—a whipping so severe that my good friend told me she felt almost afraid to report to the mother again. Perhaps the poor mother thought she was doing her duty. May be she had tried other means; but, O dear mothers, please believe me when I tell you that with these other ways I have told you of, where followed up faithfully, week in and week out, I am sure the whipping could, at least in most cases, be omitted entirely. Very likely punishment is necessary, but I begin to fear that it is given only when the parent is off from the track, as well as the child. When weeds become so large that they can not be killed with a rake, we must take the hoe and chop them up; and sometimes, after very long neglect and procrastination, the only thing is to take the scythe and mow them off. Do you see the application, dear father or mother? and do you know by experience how much better and happier a parent feels who has conquered by love instead of the rod? Why, we got so well acquainted in just that little visit with the boys that one of them said, as I told him he might go home, "Why, Mr. Root, I go to your church. Didn't you know it?"

I told him I had seen him at our church, and I was very glad he did go; and I told them, in leaving, that I should watch for them when I passed them on the streets; and I hoped to catch a pleasant look from each and every one of them, assuring me they had kept the little promise given that day to me, before the great God above.

A few months ago a young man applied for employment, and remarked that he had worked at the machinist's trade some. As we were in need of a machinist I talked with him more than I usually do, and his manner and appearance pleased me so well that I set him at work. He did not use tobacco nor bad language, and was not intemperate. His brief history illustrates the point I have mentioned in my opening remarks (that our temptations are unlike). He seemed to be a steady, faithful man; but before he had been with us many weeks I heard he was borrowing money of the hands, and getting into debt for things around town. Then somebody said he was going to get married, and bring his wife to our place. Well, about a week ago he *did* get married, and he married a girl (or child rather) only *fourteen* years old. In order to get a license he took oath that she was of age, and he is now in our county jail for perjury. Almost as soon as he came among us, some of our hands found out he was not a Christian; but he seemed so good natured, however, and willing to join in every thing good, that, before the event mentioned above, he had united with one of our Medina churches. When I visited him in jail he was bowed down with grief and shame. He put his head on my shoulder, and wept so he could hardly speak. I told him he could give better proof of his penitence, if it were *really* genuine, by dropping the past and turning in *real earnest* to Christ Jesus for help. I assured him that the Bible promise, "Come unto me, all ye that labor and are heavy laden, and I will give you rest," was true in every minute particular, and that it was open to every human being, under all circumstances, and *especially* to the sinner. But I told him there was no help from Christ Jesus, nor from his friends here in Medina, unless he told the *honest square truth* from beginning to end. He promised most earnestly to do so. He had been engaged to the young woman for only three or four months, and I asked him why he could not wait until she was of proper age. He replied that he thought so much of her that he could not bear to be away from her, and that most of the money he had borrowed was to hire livery rigs to go and see her. And yet at this time he had been paying at least *some* attention to two or more young women here in Medina. He said he did not think of there being any thing particularly wrong about it. Now, boys, I want to say a word to you right on this point. The man or boy who is engaged to some girl or woman should behave himself toward all other women exactly as if he were married. Of all the solemn engagements in this world, none should be held more solemn and sacred than the promise between two to become man and wife. God sees as the world does not see; and he who resists not evil in this line will surely repent it. "Whatsoever a man soweth, that shall he also reap." The relation between man and wife is sacred and holy, and the vengeance of a just God will come down on the head of him who trifles with this relation. Let me whisper to my young friends of both sexes, to be careful and cautious about making these engagements, as perhaps nothing else in this world can so seriously affect one's whole life. But after having once made it, let it be a sacred and solemn compact made before God. It is a serious thing for anybody to trifle with such an engagement; but ten times more so to the one who professes to be a Christian.

I next spoke to our young friend about his habit of borrowing money from people on short acquaintance. Let me put in a warning also, in regard to foolish extravagance and its attendant, getting into debt, or borrowing money. Of course, there are circumstances where it is right and proper to borrow; but for one who is supporting himself by daily wages, and who is liable to have his income suddenly cut off by sickness or other vicissitude, to borrow money for the purchase of things he could get along without, is not only folly, but it is sinful; and it is also wrong to lend money to such a one. There are more or less of these shortsighted, foolish individuals in every community, and when pay-day or Saturday night comes, these individuals are always wanting to borrow from their comrades. Believe me when I tell you it is a Christian duty and a kindness to such to speak right out squarely, "No, sir. I have no right to lend you this money, and you have no right to borrow it." Such a reproof is the kindest service you can do them. I know it is not always taken as a kindness; but I can look back now, and thank from the bottom of my heart the friends of my boyhood who were friendly *enough* to refuse me, and to point out to me the folly of my request. Now, do not think unkindly of the one who refuses to lend you money or to trust you for goods. Very likely he is not only the wisest but the very best friend you have.

I told this young friend I felt sure that this was a bad habit that had grown upon him little by little. I do not like to compare sins; but giving way to such a temptation is perhaps fully as damaging on community as either swearing, tobacco, or whisky. He declared to me that he had never been guilty of this sin before he came to our town—that he was square with the world, and owed no man except in Medina; in short, that he had resisted the Devil until he came among us. I could not believe it all. Sins like these are invariably of slow growth. The seed must first be planted, and the weeds allowed to grow for at least a time before it results in open crime. He declared to me most positively, when I asked him the question point blank, that he had never been married in his life, and had never been engaged, even, to any woman before his engagement and make-believe marriage with this child. I say "make-believe;" for he was arrested within a short time after the ceremony was performed, and the girl was sent home to her parents, with the information that she was not a married woman at all—that the marriage was null and void. I was greatly astonished to hear, when he came to be examined, that he has a wife living in an adjoining State. Now, notwithstanding my earnest talk—notwithstanding his earnest protestations that he was trusting in Christ Jesus, he had not he courage to confess to me the whole truth.

Although this young friend did not tell me so, I am afraid he has not been resisting the Devil; and the evil one did not come to him through tobacco nor strong drink, nor, perhaps, an uncontrollable temper. But for all that, the result was just the same. O friends, I wish I could impress upon you the importance of resisting Satan's whisperings at the very *outset;* and believe me, I beg of you, when I tell you that he *will* flee from you if you only *hold on.* Don't give up; don't become tired; don't say, "I can't stand it any longer." These trials are the turning-point between life and death. They settle the question between light and darkness—between sorrow and joy, and grief and gladness. These struggles with sin are for *your own good.* They will work out *glorious* things for you if you only overcome. You can not be great and good, and wise to help others, unless you resist and hold on. Stand steady and be brave, until the evil one lets go his hold and gives up and says, "That chap is bound to be good. He is so firmly planted on the rock Christ Jesus that we might as well give him up." And then, oh what joy comes to the poor persecuted sinner when Satan flees away!

EDITORIAL.

Blessed are the pure in heart, for they shall see God.—MATT. 5:8.

We are obliged to add eight extra pages this issue.

ESSAYS AT CONVENTIONS.

Short, pithy, well-written essays, suggestive of several good points, are always in place at conventions: long-winded ones, never. A long essay, however, may be valuable in proportion to its length. But it taxes the nerves a good deal more to listen to something read than something given off-hand, in animated conversational style.

THE PRESIDENT OF THE N. A. B. K. A.

Mr. Elwood is not only a successful bee-keeper, a refined and educated Christian gentleman, but he makes an excellent presiding officer for a bee-convention. He has a happy faculty of summarizing the *best* points brought out by the discussion; and when the discussion becomes a little lopsided he is pretty apt to call out the other side, although that side be against his experience and sympathies. He will make a good presiding officer for the N. A. B. K. A. next fall at Albany.

CLOSED-END FRAMES IN A TIGHT-FITTING CASE.

On page 161 it is suggested that friend Heddon includes this idea in his patent. I trust this is a mistake. Closed-end frames in a tight-fitting case were exhibited on the Ohio State Fairgrounds more than twenty years ago. Another man had a patent on a similar arrangement on the Centennial grounds in Philadelphia, in 1876, and somebody has been inventing it and bringing it out every little while ever since Langstroth brought out movable frames.

A. I. R.

THE GRIPPE AGAIN, AMONG THE BEE-KEEPERS.

It has had a little run here at the Home of the Honey-bees, but for the present it seems to have released its hold. We are just in receipt of a letter from Dr. C. C. Miller, and he says: "I am pretty badly used up with the grippe. Mrs. M. has been still worse, and mother Wilson is getting over the pneumonia. Em is laid up with a sprained ankle." Well, well, doctor, you *have* been having misfortune in your household. We extend to you our sympathies, and are glad to know that you are improving.

DADANT'S LANGSTROTH IN FRENCH.

We notice, by the last *Revue Internationale*, that this great work of our esteemed and celebrated co-laborer is at last ready for the French-speaking people of the world. It will be ready for sale on the first of March, just as this reaches our readers. We are informed that this will not be simply a word-for-word translation, but an adaptation of the book as a whole to the people of France, Mr. Dadant's native country. We predict that it will create a great stir if not a revolution in at least some districts of France. We have not learned the price of the book here in America. The price is 7½ francs in Nyon, Switzerland, at the office named above.

MR. THOMAS PIERCE AND FIXED FRAMES.

It was our special pleasure to make the acquaintance at Albany of Mr. Thomas Pierce, an enthusiastic bee-keeper of Gansevort, N. Y. He is a slim six-footer, and quite fills the bill as given us by Rambler on page 437, 1888. Said he, "So you are interested in fixed frames?" We meekly admitted that we were. "Well, you will find that not all of our York State bee-keepers use them. I don't, and some others don't." We were about to ask the reason, when somebody desired a hand-shaking, and the matter dropped where it was.

A CORRECTION.

Friend Segelkin, whose article on grading honey appears on page 134, calls attention to the fact that the words "*Not white honey*," under the head of "Grading Honey," should be "*No. 1* white honey." He says, "No doubt it was the writer's fault;" and as it passed the eyes of all here as it appears in print, perhaps the fault was not wholly ours. A second inspection of the manuscript shows that the word "not" was plainly written, but the *t* was not crossed. The omission of the period after "No." is what caused the whole trouble.

PRECONCEIVED NOTIONS.

What a lot of trouble this commodity in human nature makes us sometimes! We figure out in advance whether a thing will or will not work. Our experience with bees has been such that we are morally certain that we are not deceived, and we try hard to make all our experiments come out so as to favor our views. With enough bias of opinion we can make out a pretty straight story for or against the idea; but when such are reported it costs the fraternity much. Let us be unbiased, and ready to have our old notions broken down when facts and subsequent experience warrant it.

HOW TO KEEP BEES AWAY FROM WATERING-TROUGHS.

Among some of the good things we learned at Keokuk last fall was a little hint worth remembering, from A. N. Draper. He is an extensive honey-producer—a man who owns several out-apiaries. Said he, "People have had a good deal to say about keeping bees away from watering-troughs. I will give you a secret that is worth them all. Take a weak solution of carbolic acid, and paint it around the edges of the trough, and then they won't bother your neighbors. If you get them out of the habit of visiting such places, they will stay away." We have used enough carbolic acid in the apiary to feel pretty tolerably certain that this will work. Put this down in your note-book, and try it next season and report.

BEE-KEEPING IN RUSSIA.

The official report of the Petrowsky Agricultural Academy of Russia has just been sent us, through the kindness of P. Kuleshoff, Professor of Agriculture in that institution. The document is devoted to apiculture, and gives a general summing-up of bee culture in this country and England, in order to show what the Muscovites themselves can do if they try. Although our early education in Russian was somewhat neglected in our school days, we have succeeded admirably in translating some of the *pictures* into plain English; and these, together with some columns of figures, which seem to add up just the same in both languages, give us a very good general idea of the nature of the book, which is admirably printed — rarely equaled by our own government documents. We see the familiar name "Root" turns up in Russian as Рута (what a pity!) but the pronunciation is the same as in English. Friend Gravenhorst appears under the *nom de plume* of Гравенгорст. Seriously, we shall be glad to hear further about the growth of apiculture in

Russia, and hope that friend Kuleshoff will write us an article on the subject, for we feel sure it would be very interesting.

W. E. CLARK'S PICKLE STORY; WHY EXTRACTED HONEY SOMETIMES DOES NOT SELL.

Among other good things given us by W. E. Clark in the convention at Albany was what we will call his "pickle story." A groceryman had had for a year or so half a barrel of pickles under the counter. A new clerk was hired; and, seeing the pickles, asked if they were sold. His employer replied that they were a drug on his hands. The clerk very modestly volunteered the information that he could dispose of the whole lot in a few days. The employer told him to go ahead. The clerk procured some nice square bottles, filled them with pickles, corked them, neatly labeled them, and, last of all, he put them in a conspicuous place, and, presto! they went off like hot cakes, at a good big price. Said Mr. Clark, in moralizing on this point, "The customers did not know that the groceryman had pickles for sale; and even if they did, they did not have some neat packages of them *constantly* in sight as a reminder of the fact that these things were for sale. That is just the trouble with extracted honey in many of our groceries," continued Mr. Clark. "It is sent to the groceries in bulk, and then they are *not* supplied with attractive packages to exhibit the article; and many times, if supplied, the packages are allowed to become fly-specked, and the honey to become candied." It should have a neat, clean, and fresh appearance. If people do not want to buy it in packages, let them have it in bulk, but let them see that honey is for sale in attractive glass packages. They make the best sign.

THE HAPPIEST MOMENT OF A BEE-KEEPER'S LIFE—A LITTLE ADVICE TO THOSE WHO DON'T READ BEE-BOOKS.

The happiest moment in a bee-keeper's life is not when he becomes the father of a newborn babe of flesh and blood (although that is a supreme moment, so it is said), but it is when he becomes the father of a baby in the shape of a *new-fangled bee-hive* that is "warranted to revolutionize bee-keeping in the near future." Very proud he is of that baby for a while, and jealous is he that no other shall try to snatch it away from him, and he gets the United States courts to protect him. But his "baby," after a while, does not come up to his expectations. Somehow, as the years go by, it doesn't take to the *bees*, and the bees don't take to *it*. The ultimate result is, that it is piled up in the back yard, along with a lot of others. Almost every beginner has been through the experience; but sooner or later he repents, buys a good bee-book, and starts right. There is lots of fun in inventing a hive that will beat any thing ever before heard of. But we urge, *don't*. Don't waste any time or money until you have thoroughly read the A B C of Bee Culture, or, in fact, any standard text-book on the subject. About every week we receive a letter from one who has got a hive, the special features of which he is not yet prepared to divulge, but which he is *sure* is something far superior to those devised by the "fathers" of bee-keeping. By and by, when it *is* divulged, a little inquiry elicits the fact that it is older than the hills, and a little better than the "old log gum;" and that the happy (?) inventor has not even read a bee-book.

LAYING OUT AN APIARY; SEASONABLE HINTS.

It is about time now that we should be thinking of locating our apiaries. Experience has shown that we can not afford to go to any great expense in providing suitable shade. There are plenty of locations that afford shade naturally for at least a part of the day. A young orchard is an excellent place. It may be well enough at our home yard to go to considerable expense in putting up grapevines or other shrubbery; but it certainly will not do for an out-yard. Experience has shown, in many instances, that a yard that has in years gone by furnished tons of honey is now practically worthless, or so nearly so that the moving of the bees to some location more favorable is a necessity. For instance, four or five years ago an apiary furnished an abundance of basswood honey; but the basswoods have all been cut off; there is no clover, and the field is worthless. Again, a locality has once furnished immense quantities of white clover; but extensive agriculture has set in, and clover pasturage has given way to immense wheat-fields. The inroads of civilization sometimes damage the honey-bearing resources of a locality; and, conversely, sometimes make them more valuable. There are a few locations in York State that formerly gave but very little honey; but the farmers, in recent years, have introduced buckwheat to such an extent that these are now splendid buckwheat countries; and the yield of this dark rich honey plays a considerable part in the net profits of the season. In a word, we want our apiaries so we can load them up at a moment's notice, and move them at practically little expense to any new field that may be more inviting. We can not always tell at first whether it will be a favorable location or not. If it does not come up to our expectations, we can "pull up stakes" and try elsewhere again. If you can locate near swamp land you are fortunate.

W. L. COGGSHALL'S EXTRACTOR; COMBS HANGING IN THE BASKETS THE SAME AS IN THE HIVE.

In between the sessions we had a very pleasant visit with W. L. Coggshall. He is one of the largest honey-producers of York State, and runs for extracted honey almost exclusively. Said he, as our conversation turned to extracted honey, "I do not like your extractor."

"Why?"

"Because the combs do not hang in the extractor-baskets the same as they do in the hive."

"Why, that makes an extractor so cumbersome and awkward," we interposed.

"Not at all," said he. "My can is only 30 inches in diameter and 30 deep. The baskets are made to take the combs just as they hang in the hive, and will hold four frames at a time. When I pick a frame out of a hive I do not have to turn it over endwise, and let it down into a deep basket. I pick it up just as it comes out of the hive, and put it squarely into the machine. In reversing the combs there is another advantage. Combs pick up easier, and go back into their respective places with less trouble. Why," said he, "I can not begin to extract the amount of honey with one of your extractors in a day that I do with one of my machines, and I have tried both."

"What gearing do you use?" we asked.

"The upright."

Mr. C. has the reputation of producing immense crops of honey, and he also runs, in connection, a farm; and with the help of one assistant he does the work alone, practically. We have not had calls for an extractor to hold the Langstroth combs as they hang in the hive, to any great extent. We are quite willing to make whatever bee-keepers want, although it should be remembered that such an extractor would cost more, and very possibly would not please some as well.

Our subscription list is now 10,097.

WHO IS RAMBLER?

WE will tell you in our next issue, and give you one of those beautiful half-tone portraits of him.

"DOWN BRAKES!"

A MOST excellent article appears from the pen of L. C. Axtell, on page 169. We commend it to the thoughtful consideration of every reader who is interested in new developments.

CHALON FOWLS.

WE have just had a very pleasant call from Mr. Chalon Fowls, of Oberlin, O. He is one of those enthusiastic and thoroughly practical bee-keepers whom it is a pleasure to meet. He is so full of bee-lore that *even an editor of a bee-journal* may get some new ideas in talking with him.

REFRESHING RAINS IN CALIFORNIA.

THE following little gleam of news comes to hand from one of our California subscribers:

> Our long drouth in Southern California is at last broken by a most refreshing rain of 3½ to 4 inches at this place. Of course, we feel wonderfully thankful, for it not only puts our honey prospect on a good footing, but almost insures a general variety of crops. ALLEN BARNETT.
>
> Whittier, Cal., Feb. 17.

SECTIONS MADE OF RED WOOD.

MR. J. W. UTTER, of Amity, N. Y., sends us samples of sections made of red cedar. The wood is of a reddish-pink cast, and has the characteristic odor of an ordinary leadpencil. Mr. U. says these sections set off the honey, and make the combs look whiter. By the way, wouldn't that strong odor of red wood rather give a flavor to the honey? It would be like making butter in a new cedar churn. The butter would surely taste of it.

TWO MORE NEW BEE-JOURNALS.

THE first one, a monthly, hails from Berlin Falls, N. H., and is entitled the *White Mountain Apiarist*, and contains 12 pages. The second has 16 pages and a neat tinted cover. It hails from San Francisco, Cal., and bears the name of the *California Bee Keeper*. This latter is very neatly and tastily printed. Let's see: Mr. Newman, of the *A. B. J.*, a few weeks ago counted up five new bee-papers for the new year, and here are two more—seven in all. Still there is room. Next!

P. S.—One of our compositors suggests, on seeing the above, the wisdom of starting an obituary department for bee-journals. Two have already suspended publication within two months—not of the number, however, of the new year. *We* were not mean enough to think of such a thing; but, say, if the new publications continue to start up at this rate we shall have to have a department of "New Bee-Journals."

THE EDITORIAL "WE" IN THIS DEPARTMENT.

OUR readers will observe that we have been employing the plural form of the personal pronoun in this department, in spite of the fact that Dr. Miller has urged in the *Bee-Keepers' Review* some very good reasons why the singular form of the word should be used. We like the personality of "I," but do not see how we can consistently use it with justice to other members of the Home of the Honey-bees who use their brains. E. R. R. dictates most of the editorials; but while in most cases the editorials are the expressions of his own opinion individually, they are also very often the expression of three or four in our establishment. For instance, take the matter of using square kerosene-cans for shipping California honey. E. R. R. consulted Mr. J. T. Calvert, business manager, and the shipping clerk in the express department, as well as several of the boys who have to do with the handling and testing of the honey in these oil-cans. Now, we can't very well say *he* did so and so; but we could say with truth that *we* did. Very often an editorial is suggested by our superintendent, and an opinion is rendered by him; and E. R. R., in conning it over, digests it and finally gives it to the stenographer; and it very often happens that as he takes it down he suggests some other ideas. E. R. R. fears that, if he were to use the singular pronoun, he would be unfairly credited with an unusual amount of wisdom; and if it seems necessary, for one reason or another, that the individual personal "I" should be used he adopts it, and then he signs his initials. For instance, if he picks a bone with Mr. Heddon, the latter knows who is responsible for the statements.

GRAND RAPIDS LETTUCE, ETC.

IT is refreshing to notice that my two children in the line of garden products, namely, Grand Rapids lettuce and the Ignotum tomato, are taking such prominent places in the seed catalogues of the world. Perhaps I should say the two children I *introduced*, for of course I did not originate either of them. I believe that few or none of the catalogues give me any credit for my efforts in that line; but so long as they have met with great favor, I do not know that it matters. I omitted to mention that our friends at the Experiment Station, at Columbus, have made some very careful experiments to determine how much of an improvement the Grand Rapids is over its parent, the Black-seeded Simpson, large beds of which were in their greenhouses, side by side. The Grand Rapids shows a marked superiority. It has a better color, and will keep longer out of ground; so the claims that our friend Eugene Davis made for it are certainly honest and deserved. By the way, quite a few do not seem to understand that the Grand Rapids lettuce is just as well calculated for outdoor culture as in the greenhouse. As it does not form a head, however, a good many prefer the Boston Market or Henderson's New York for growing in the open air. A. I. R.

HUBER LEARNING TO READ.

As the young hopeful is now nearing seven years of age, and has never heretofore manifested any special liking for books, I began to be a little surprised. If he is going to be a chip of the old block, thought I, he must pretty soon begin to get a glimpse of the wonders this world has to offer, especially in the line of literature. Well, about a week ago he took a great fancy to a book called "Bible Pictures, and what they Teach us;" and before we knew it he was spending all his leisure time poring over its pages. When Sunday came, of course there was no reason why he should not continue, with *such* a book. His favorite attitude is to spread the book and himself on the floor, in the center of the room. In this way he can change his position, and sprawl out first one way and then another, and thus he keeps it going. After dark he has a big bright lamp down on the floor by his side. I was a little curious at first to see what book he had selected among the multitude of books that are to be found almost everywhere. The book is the work of the author of Story of the Bible. A. I. R.

A NEW METHOD OF TREATING DISEASE WITHOUT MEDICINE.

WATER CURE APPLIED INTERNALLY AS WELL AS EXTERNALLY.

Wash ye, make you clean.—ISA. 1: 16.

With the present amount of interest in this matter of internal bathing, or the use of the "drugless remedy," as it has been termed, I feel as if I could no longer keep still consistently; and even though the subject I take up may seem to some an indelicate one, when we take into consideration the amount of human suffering that may be relieved by it I think we are excusable for talking plainly, and even using very plain terms, in print. In Titus, 15th verse of the first chapter, we read, "Unto the pure, all things are pure; but unto them that are defiled and unbelieving is nothing pure; but even their mind and conscience is defiled."

One reason why I feel moved to take the matter up to-day, and make it as plain as I know how, is that so many are, at the present time, *making capital* of selling one of the uses of pure water, to their fellow-men, as a *secret*, as if it were right or proper to receive money for telling how to make use of God's gifts, such as pure water, sunshine, pure air, etc. It seems sad to me that at least a *part* of the world should be stumbled over such a simple matter, or should imagine it right to keep from our neighbors a knowledge of a plain, simple plan of removing suffering by the use of water; yes, water, and nothing else. If any one should feel like questioning my authority or my moral right to make this secret free and public property, I will quote, at the outset, from a little book published by Fowler & Wells in 1847.

The book referred to is "The Water-cure Manual," by Joel Shew, M. D., copyrighted in *1847*, printed by *Fowler & Wells in 1850*. Speaking of these injections Dr. Shew writes:

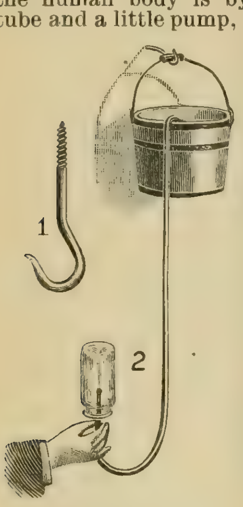
"They may be repeated again and again, n as great quantity as desired. . . . A good mode, too, is to take a small injection, a tumblerful, more or less, that is retained permanently, without a movement before morning. This is very soothing to the nervous system; aids in securing sound sleep, and, by its absorption in the coats of the bowels, dilutes acrid matters therein, tonifying and strengthening likewise those parts, and aiding materially in bringing about natural movements."

After naming various diseases for which this remedy is invaluable, he says:

"This statement will cause sneering, I know; but it is no fancy sketch. The thorough washing out, so to say, of the lower bowels, by which the peristaltic, or downward, action of the whole alimentary canal, is promoted, and by the absorption or transudation of water its contents are moistened and diluted, and the whole of the abdominal circulation is completely suffused by that blandest and most soothing of all fluids, pure water. Whoever understands well the sympathies and tendencies of these parts of the human system will at once perceive the truth of what I affirm."

The above, you will notice, contains the whole of the secret—or, at least, so much of it that no reasonable individual can pretend to call it new, or a real discovery of the last few years. Our older readers will remember vividly the time when Fowler & Wells created such an excitement throughout the world by what they accomplished by the use of water and nothing else—water used hot or cold as the occasion demanded, or lukewarm. Vapor baths also was another form of using hot water. While, perhaps, all the claims made fifty years ago have not been fully realized, yet I feel sure the world has been made better as well as *cleaner* ever since this water-cure excitement. At different times the use of water in large quantities, taken into the system by way of the mouth, has had its advocates. Dr. Salisbury for many years has been accomplishing a good deal by "feeding" his patients on *hot water*. We have all seen painful sprains and bruises cured almost as if by magic by the use of water as hot as the patient can bear it. If you want to get out a corn, first soak your foot in hot water; and many surgical operations can be performed with comparative ease where hot water in *sufficient quantity* applied for a *sufficient length of time* is used to relax the muscles and to soften the skin and flesh. Physicians have for ages (for aught I know) used water, both hot and cold, in the form of injections; and the wonder is, at the present time, that they have been working so close to a great discovery, as it has been called, without realizing the wonderful things to be accomplished right along in that line. Perhaps my good brethren of the medical fraternity feel like smiling a little at this last remark of mine. Well, smile if you like, my good friends; in fact, I rather think you had better smile, for a world of suffering people are beginning to smile right along on this line, and we are *going* to smile and have more vigor and energy to thank God for this new gift.

As near as I can make out, the discovery consists in using more water—perhaps hotter water in some cases—and using it for a greater length of time. If we wish to wash a jug, it is an easy matter to make the outside very clean. We can use hot water, soap, and ashes, if need be. We can rub and scour dirty spots; we can use a brush and a cloth, and some sand, if need be, but not so with the inside. You can pour in hot water and pour it out again. You can put in soap and ashes, and shake the jug vigorously, and you can put in water again and again, until you judge by what comes out that it is clean enough to be used for food. Well, this matter of internal bathing is a good deal as it is with the jug. We want lots of water; and in order to perform its office thoroughly, it may be necessary to let this water remain for some time, just as we let it remain for some time in the jug, that it may soak up and loosen accumulations on the sides, where no man can see. After this soaking-up process, a vigorous shaking will probably do much to remove every last vestige of accumulation. A customary way of introducing hot water into the human body is by means of a rubber tube and a little pump, or ordinary syringe, such as we find in great plenty at our drugstores. But I have found something not only very much better but even cheaper; and this little picture will, I think, make it all plain.



APPARATUS FOR INTERNAL BATHING

Fig. 1 represents an ordinary screw-hook, made of heavy wire, such as you get at the hardware store for two or three cents. This is to be screwed into the wall so as to support a pail of water. Instead of hanging the pail as in the cut, however, I would turn the hook a quarter around and hitch it on to the pail at the ear right where the bail is attached to the pail. The rest of the apparatus is simply a piece of rubber tubing (¼ inch, outside diameter) about five or six feet long. Twenty or twenty-five cents would cover the whole cost of the apparatus. Where the rubber tube goes over the side of the pail, it must be kept from slipping by means of a little wire staple put across it; or you can, if you choose, tie it by a string at one of the ears of the pail. It should go inside of the pail so as to reach to the bottom, that it may take out all of the water. To start the water, throw the tube in the pail, so it sinks clear under the water. Now take hold of one end; and as you do so, pinch the sides of the tube so as to close it. Bring it over the outside of the pail, and the water will run of itself. If you bring it down below the pail, as shown in the cut, the water will be thrown from the end of the tube with considerable force; and it is just right to wash out a jug, bottle, or any thing else, for the force of the jet will make it strike every part of the bottle. Now, you are to cleanse the human body just as we wash out the glass jar in the figure. Please bear with me now, friends, a little, even if I speak very plainly, in order that those who are awkward with such appliances, just as I was myself six months ago, may have no trouble in managing the matter. When I spoke to my mother about it, a few days ago, she said, more than 50 years ago she saved the life of a neighbor in just this way when no physician could be obtained. The doctor told her, when he arrived, that the woman would have been dead before he reached her had she not used this simple remedy. The only difficulty about the operation is in introducing the end of the rubber tube into the body; and this, I suppose, would be an impossibility with the average patient did we not depend upon the good offices of the hot water before mentioned, in its power of relaxing the muscles. The pail should be at least two-thirds full of water, and I would have it about as hot as it can be and permit you to hold your hand in it. Now let this stream of hot water play for a little time against the external part of the organ that ordinarily closes itself involuntarily by muscular contraction. In a very brief time the hot water will have the effect of relaxing the muscles, and after the pressure of the water has forced a little of the liquid through the opening, all difficulty in that direction has disappeared. The question naturally arises, "Is there no danger of injuring the delicate machinery of the human system?" I am sure there is none whatever. The more water you can get into the *colon*, as physicians term it, the better. More of this, however, anon. I am told by members of my own family, however, that not every one can use a simple rubber tube as I do. In that case, put on the end of the tube a hard-rubber nozzle, such as is used on an ordinary syringe. I presume different people will need to vary the plan somewhat. But I have never heard of anybody yet who did not succeed finally in getting the water to fill the colon in a satisfactory way. Introduce as much water as possible. Two quarts is better than one; and if you can store away a gallon you will probably make more effective work than with a smaller quantity. If it persists in bursting out, use a cloth or other means to restrain it. I would first wash the colon clean from every thing it contains. Get out every thing that can be made to pass out with the water; then fill up again with clean water, retaining it while you walk about; or if there is difficulty in removing all accumulations, get some friend to roll you and shake you, kneading the bowels, if need be, the same way I spoke of in cleaning the jug.

☞Right here comes something of my own invention; that is, I have not heard of anybody else using water in *just* the way I do. It is well known that a running stream will thoroughly cleanse many substances better than any other means of using water. The reason is, the current constantly carries away all impurities, and fresh clean water is constantly taking the place of that charged with the matter to be removed. Well, I accomplish the above result by letting the rubber tube remain in its place until the colon is thoroughly cleansed, and the water entirely emptied from the pail. The plain rubber tube, without any nozzle of any kind, gives a larger stream of water, and finishes the cleansing much quicker, than where the hard-rubber tube is used. If you do not find yourself cleaner than you have been before in years I shall be mistaken.

Let me give you a little of my experience: During all my life I have been more or less subject to what is called summer complaint and trouble with the bowels. My wife, years ago, recommended this water remedy as ordinarily applied by physicians. But I got a notion in my head that it was unnatural, and tinkering with Nature's business. The very thought of the thing, also, had something repulsive about it to me. I thought it was well enough for old women, and possibly for babies and sick people, and so I went on suffering. After I had paid $4.00 for the secret, however, I could not very well do less than to make a test of the thing that was recommended so highly. Of course, I succeeded without a bit of trouble; and, to my astonishment, before I got through I removed a vast amount of trash of different kinds that my nose bore vivid evidence to being unfit to lodge in the human system. Now at this time I was not conscious of being in particularly poor health. In fact, I did not suppose that I needed any remedy of any sort; but in my eagerness to see whether the new drugless remedy was what it claimed to be, I determined to give it as full a test and examination as I could. In order to see whether any injury or even unpleasant symptoms could result from a very frequent use of the internal water bath, I used it for some time, every day; lately from two to three times a week. I was agreeably surprised to find that the very offensive smell given forth on first using it did not manifest itself again; and I was led to conclude that this superfluous matter, if taken from the system at once, need not be particularly offensive. On waiting, however, for ten days or more, the same peculiar offensive smell was present; and after having used the remedy for six months or more, together with the testimony of great numbers of others, I am ready to conclude that it is no more harmful than bathing the body, or even washing the face. Some may urge that it is not according to nature. But, my friends, few things that we do nowadays are "according to nature." I am not sure that washing the face is "according to nature." I am sure, however, that washing the whole body greatly *assists* Nature in her efforts to ward off disease. The Bible commends it in our text. When you urge "nature," you should remember that man is uneducated by nature. The savages in the isles of the sea are a specimen of nature without civilization and the restraint of Christianity. They are not only heathens but cannibals. Now, I can not tell why God left humanity through all these ages without this knowledge which seems at present so conducive to our health; and when we come down to the real truth of the matter, he did *not* leave us without it. The thing has been before us for hundreds of years. We simply have been dull in appropriating the knowledge that was before us so long.

I do not know how many forms of disease this matter of internal bathing will remove. I suspect, however, that people in general will enjoy much better health in every way if the waste matter of the system be thoroughly removed about as fast as it accumulates. Typhoid fevers are considered at the present day as being the result of bad air, bad water, and unwholesome smells in our cellars and around our buildings. Is it any thing strange that the continued presence in the human body, of the most offensive matter we can imagine, should be the cause of disease? Physiologists tell us, if I am correct, that the elements and juices of our daily food are constantly passing into the circulation, even after they have passed the intestines and reached the colon. If this be true, our systems may be poisoned by secretions from this offensive matter. In a state of health, very likely nature takes care of this; but, unfortunately, few people are in the possession of full health. A man or woman who is thoroughly well in every way is the exception and not the rule.

During the past year, quite a few testimonials have been given in these pages in regard to this drugless treatment of disease, and I could easily fill this present number of GLEANINGS with testimonials, many of them astonishing ones. I will, however, for the present, content myself by giving you simply my own experience. For several years past I have been having occasional distressing spells of sick-headache, sometimes accompanied with vomiting. I am very apt to have these spells while traveling. One such attack nearly spoiled my visit at Dr. Miller's. While at Madison, Wis., during a beautiful winter night, I suffered from severe headache and sickness at the stomach for more than four hours. Those who have similar attacks know something about the suffering that accompanies it. So far as I know it was caused by eating a fine large apple during a buggy-ride across the country, the afternoon before. I thought that, if I was getting so I could not enjoy even an *apple* without trouble in my digestion, I was getting into a bad state. These periodical headaches kept getting more and more frequent, and I began to think my health was giving way in that direction. If somebody had told me, during that night in Madison, that I could have perfect relief in three minutes, without using any sort of drug or medicine, I would willingly have given *ten dollars* for the privilege of lying down to rest, and getting the sleep I needed, so as to fit me to enjoy the convention next day. Well, during these past six months I have had a number of attacks of this same sick-headache and distress from indigestion. The new remedy has given perfect and immediate relief every time. It seems to be the result of accumulation in the colon. When this is removed out of the way, and the apparatus thoroughly cleansed and put in working trim, Nature goes buzzing along her way. Once upon a time I used to run a small gristmill by windmill power. The mill would occasionally become choked, and it then had to be pulled to pieces, and the surplus meal got out of the way, and then it would go on as lively as ever. It seems to me that the human machine, given us by the great Father above, occasionally gets in this fix, and then the hot water gets it in perfect trim.

A great part of my earlier life was devoted to clocks and watches. I have also been more or less intimately acquainted with the physicians of our town. You may wonder what clocks and watches have to do with this human machine. Listen: Once or twice I have been invited to be present during examination of the human body, to determine after death where the difficulty lay. In one case that baffled the physicians, dissection revealed the fact that the valves of the heart had become ossified. At another time, a lady, a distant relative of mine, was doctored and drugged for months for a complaint that all doctors thought was of the reproductive organs. An examination after death showed these organs to be in a perfect state of health. The whole trouble was what they call intro-susception—a mechanical derangement of the colon. Of course, the trouble was in the *neighborhood* of the organ they were doctoring; but when the real truth came to light, they found they had been giving the most powerful drugs known, in the attempt to do something for an organ that had nothing to do with the disease that produced her death. Now, when a watch or clock is deranged we pull it to pieces to see what cog is broken or what tooth is bent. Then we can easily confine our efforts to the precise spot where the trouble is. How often I have wished the human body could be taken apart in the same way, that we might not be blundering in the dark! Well, the medical world is making great progress in just this line. By the use of the knife they go right to the point of disease, and in many cases fix it as we would fix a watch; and I confess that, when I first discovered that we could flood and cleanse at least a great part of the internal body, it seemed to me a great step toward what I had been so long looking for.

I believe our physicians do not all agree that this water thrown into the colon can make its way into the bladder; but when they take that ground, they are certainly at fault. Almost any one who has used the treatment *thoroughly* will tell you that quite a portion of the injected water can be passed off through the urinary organs. If this be true, then you can, by the same means, rinse from all impurities, accumulations, and secretions, the urinary apparatus as well; and I am sure that I have received great benefit in just this line.

Of course, great things are claimed for this new remedy. Some of those who sell the secret have enumerated a long string of diseases that may be cured by flushing the colon. I suspect there is great exaggeration in this line; but for all that, I would recommend that every person who is out of health from *any cause* should go to work carefully, and see what effect this treatment will have. If you are weak and in poor health, and take cold easily, be sure you do the work in an apartment sufficiently warmed so that you may not take cold by drafts or exposure. Although I have never heard of trying it for a patient in a chill, it seems to me it is far ahead of bottles of hot water, hot bricks, and every thing of the sort. I should say, from personal experience, that the hot water goes directly into the circulation; for I can feel the warmth clear to the ends of my fingers, and toes, after using it for, say, five or ten minutes. Just think of the effect on the system, of introducing into the body, say, half a gallon of water just as warm as you can possibly bear your hand in it! I have counseled with quite a number of good physicians before writing this, and the general opinion seems to be that it certainly can do no harm, even if it does no good. Therefore let us be clean and keep clean, as in the language of our text; and when we have done every thing we can along this line, we have certainly *paved the way* for Nature to go to work vigorously in her work of patching up and fixing up.

There is one unpleasant feature connected with this drugless remedy. In my instructions I have planned to have the pail hang up in the ordinary out-building belonging to most rural homes. The trouble is this: Before you get through, your clothing will become scented unpleasantly. A chimney attached to the out-building, so as to carry the bad-smelling air clear out at the top, would be a remedy. The close out-building, with a vault underneath, with no chance for a circulation of air, seems to be the worst arrangement we can have in this one respect. A very open building, so that the air can blow freely through and all around it, would probably not scent the clothing. A friend suggests that the form of water-closets used in cities, where water and nothing else is used to carry away accumulations, is a perfect arrangement for the drugless remedy. The Smead system will doubtless work beautifully, only they are not so arranged, usually, as to dispose of so large a quantity of water. If this new remedy, which commends itself to every one who loves cleanliness, comes largely into vogue, as I suspect it will, our out-buildings must be planned especially for them. It seems to me that this is a matter that not only our *health-journals*, but our rural and agricultural journals, should take in hand. In our family, one member has been perfectly cured of a chronic diarrhea of years standing, that threatened to be something very obstinate and serious. Another has been receiving great relief from a tendency in the opposite direction; and wherever it is used, so far as I know there has been but one verdict. A good many of my friends and acquaintances have paid $4.00 for the remedy; and in several cases no one knew they were using it until those around them began to notice a wonderful improvement in the general health. When questioned, this drugless remedy was the explanation. Our printers are instructed to have several thousand copies of this paper printed for free distribution. We will mail to any of the readers of Gleanings, or, in fact, to anybody else, just as many as they want, to give to whoever needs it; and the more calls you make for them the better I shall be pleased. I have had, as you may know, some experience in furnishing without pay things that benefit mankind. He who is working to benefit his fellows will always find the wherewith. God himself will see to it, when the work is done within the bounds of reason, and in a Christian way. I should be glad to answer any questions our friends may see fit to ask. One great reason for writing this paper is the *general* desire for information in regard to this whole matter—not only from my own acquaintances here in Medina, but from far-away friends.

SPECIAL NOTICES.

THE HUBBARD SECTION-FORMER.

We can furnish this machine, described elsewhere, for $2.50. It weighs 24 lbs., and its extreme length is 5 feet.

THE HONEY MARKET AT MEDINA.

Honey is going off some better of late, especially to-day (26th) when we are shipping 100 cases (12,000 lbs.), in three lots. Most of this is for manufacturing purposes, and goes at a special price. For prices we refer you to page 43 of No. 2, current volume.

PLANET JR. CULTIVATORS AND TOOLS.

We have the new 1891 catalogue of these valuable garden implements. A number of new tools have been added to the list, and old ones improved. Besides, we can make better prices than usual. We have the catalogue ready to mail on application, and in each is a sheet giving our net prices, which are from 15 to 50 per cent below catalogue prices. If interested, write for catalogue.

MAPLE SUGAR AND SYRUP.

The maple season opened early this year, and the sugar and syrup produced thus far excel the average in quality. We have a limited quantity on hand, which we can furnish at the following prices: Syrup in 1-gal. sq. cans at $1.20 each; $11.00 for 10; $21.00 for 20 cans. In 5-gallon cans, if preferred, at 5 c. per gallon less, when we have it put up this way. Choice sugar at 10 and 11 cts. per lb.; ½ ct. less in 50-lb. lots; 1 cent less in barrel lots of 300 lbs.

WHITE-CLOVER SEED.

We have a nice lot of this, which we bought so as to be able to make the following price: $8.00 per bushel; $4.10 per ½ bushel; $2.20 per peck; 18 cts. per lb. White-clover seed has always been higher than alsike till this year, but we can now sell it lower. The time to sow these seeds is during this and the next month, according to locality. Alfalfa clover seed at $7.00 per bushel; $3.60 per ½ bush.; $1.90 per peck; 15 cts. per lb.

JAPANESE BUCKWHEAT WANTED.

Those having choice clean Japanese buckwheat seed to sell will do us a favor to mail us a small sample, and write how many bushels (50 lbs.) you have to sell, and the price you ask for it. Remember, that, as we are selling it lower than last year, we expect to buy it lower. As a rule, it is selling for about what the millers pay for it to grind. Choice clean seed brings a little higher price.

ALSIKE CLOVER SEED.

We advanced the price of this the first of January to $9.00 per bushel; $4.60 per ½ bushel; $2.40 per peck; 20 cts. per lb., bag included. Since then the market has been very firm—at one time as high as $9.00 wholesale, in large lots, bags extra. We expected to have to advance the price again, but the demand has slackened, and the market is easier, so that we propose to leave our price where it is, although at this price we sell on a very small margin. We have choice seed, ready to fill orders promptly.

CAULIFLOWER SEED FROM H. A. MARCH.

We have just received by mail a pound of seed, and here is what friend March says about it:

> It is of 1890 growth, and I cut and sold in market every head that was not "perfection." It is really stock seed that I grew last year. My reports from the stations are better this year than last; and all growers who used my Puget Sound seed are sending for it again this year. H. A. MARCH.
>
> Fidalgo, Wash., Feb. 7.

The price will be 5 cts. per packet; ⅛ ounce, 25 cts.; ¼ ounce, 40 cts; one ounce, $1.50. Our friends will notice that these prices are lower than they ever have been before, and at the same time the quality of the seed is superior to any thing that has ever before been raised. When you get an orthodox *bee-man* to raising seeds, or any thing else, he generally "gets there" sooner or later.

WHITE AND CREAM SECTIONS.

Owing to an exceedingly open winter in Ohio a year ago, there was very little basswood cut till spring; and this spring, cut lumber is not a clear white, but more of a cream. Had we not secured about 150,000 feet of extra nice white lumber in Michigan, we should have been poorly supplied for white sections. This winter we have already twice our usual year's supply of the nicest white basswood we ever had. It will be a month or six weeks yet before any of this is dry enough to work into sections, and we have got to the end of our dry white from Michigan, last year's cut. We have white 1-lb. sections in stock, 7 to foot, 1¾ and 1⅞ inches wide; but, until our new lumber is ready to work we shall have to furnish other widths and sizes in cream color. Of course, we will furnish these cream color at a lower price, and many of you no doubt would just as soon have them at the lower price. We have just been rigging up our dry-house so we can hurry up the seasoning of the white lumber more than ever before; and as this comes to your notice this dry-house is running full blast. We have only a limited quantity of lumber for cream sections, and make this into sections only because of the present dearth of white. As soon as our white lumber is dry enough we shall discontinue the cream grade.

PRICE OF 1-LB. SECTIONS.

The price of a single thousand 1-lb. one-piece sections, with most of the manufacturers and dealers, is $3.50. In larger lots the price varies somewhat. To be uniform with other large dealers we make the following:

Quantity.	No. 1 white.	Cream, when we have them.
Less than 250, per 100	$ 50	$ 40
250 1-lb. sections	1 00	80
500 to 2000, per 1000	3 50	3 00
2000 1-lb. sections	6 50	5 50
3000 "	9 00	7 50
5000 "	14 00	12 50

Prices of white sections in larger quantities made known on application. Cream sections are not sold for less than above figures in any quantity.

VEGETABLE PLANTS FOR MARCH.

Well, I suppose we might as well confess we have not any, unless it be Palmetto asparagus and strawberries. We have a few cold-frame Jersey Wakefield cabbage-plants, but not enough good ones to offer them for sale. We have a great lot of plants raised from seed started in the greenhouse in January and February, but none of these will be real nice to send out before the middle of March. The same is the case with *transplanted* lettuce-plants and celery-plants. Plants from the seed-bed we have abundance, of cabbage, lettuce, and celery. But these are so delicate, and need so much care, both in shipping and transplanting, that about half of the time they do not amount to much. We can send them if you wish, at the prices we have in former years; but unless in the hands of an expert, they (seedlings) are often not a success. We can furnish asparagus-plants and strawberry-plants at 10 cts. for 10; 75 cts. per 100, or $6.00 per 1000. If wanted by mail, add 5 cts. for 10 or 25 cts. per 100. The four strawberry-plants we have selected to offer for spring planting are the Jessie, Bubach, Gandy, and Haverland. The Jessie and Gandy are growing in the greenhouse, so we can take them up at any time. The Bubachs are in the open air; but as we seldom have much frost in March, we can take them up almost any time. But of the Haverlands, our stock is already exhausted, and we are waiting for a shipment of 5000 plants which we have engaged as soon as they can be taken up. We are going to put these out in our rich plant-beds, under glass; but we prefer to have them make some growth before sending them to customers; therefore we can not furnish you Haverlands right off now. We can send all the rest promptly.

SECOND-HAND FOUNDATION MILLS.

We have on hand to dispose of, the following second-hand mills. As a rule we consider new machines the cheapest to buy, even at a much higher price; but there are circumstances when a man wants to make only for his own use, and can not afford a new machine when it may be profitable to buy an old one.

One 12-inch Dunham mill, formerly used by Dadant, and in fairly good order; makes heavy brood foundation with round cells. It sold when new at $50.00; will sell now for $18.00.

One 10-inch, our own make of several years ago, in fair condition, will make fairly good brood foundation; will sell for $10.00.

One 10-inch, of our make, in fair condition; used some more than the last, but well taken care of; a brood-foundation mill; will sell for $9.00.

One 6-inch mill, of our own make a number of years ago; better adapted to brood than section foundation; will sell for $6.00.

We have also a new 8-inch mill for thin surplus foundation, hexagonal cell, which is a size we do not advertise. It has not been used, and is first class. Price $17.50.

It seems as though we never had such a demand for foundation mills during what we call the "dull season" as we have had the past few months. We planned to fill all orders, and get some mills ahead so we could be more prompt in filling orders during the rush. We hoped, also, to get a little chance to experiment with a view to further improvement; but no chance has come. Instead we are behind on mill orders already, and have been more or less behind for a month or two back. We are working three men in this department, and turning mills out at the rate of nearly two a day, so we hope soon to be up and have some machines ahead. The mills we are turning out now are better than ever. On the ten-inch machines we now put only one pair of gears, which answers the purpose fully as well as two, as formerly used.

OUR $8.50 BEE-KEEPING OUTFIT FOR BEGINNERS.

There are a good many beginners who feel all at sea when they get hold of an apiarian catalogue. They want to start to keeping bees, but do not know exactly what they want, and can not afford to buy a lot of stuff they do not absolutely need—at least, until they have a larger apiary or more experience. For the convenience of just such people we have selected an outfit that gives a beginner all that he absolutely needs as a start. He should have a few hives, and the necessary tools for handling bees, and, not less important, a bee-book. We append the following table, selected from our 52-page catalogue, mailed on application.

One A B C book, bound in cloth	$1.10
One No. 2 bee-veil	.60
One Clark smoker	.50
Five No. 1 Dovetailed hives, complete, in the flat, for comb honey, including all inside furniture, sections, separators, etc.	5.56
2 lbs. light brood foundation	.96
Total	$8.66
We will lump the whole in for an even	$8.50

Directions for nailing and putting together will be put in with each package, giving sectional drawings showing each part. There possibly may be some who would prefer to see a hive nailed up. For $1.50 more, or an even $10.00, we will send a No. 1 Dovetailed hive, put up nailed and painted, complete, for comb honey. The material in the flat or knock down will be so packed that there will not be more than 2 lbs. of crating, and will go for third-class freight. The freight in this and adjoining States will be from 50 cts. to $1.00.

The A B C of Bee Culture will give the necessary instructions how to start. Read Transferring, Nuclei, Comb Foundation; and, as the season advances, Comb Honey and Swarming. Along in the fall you will need to read carefully Wintering. All of these subjects will be found in their alphabetical order.

FEEDING BEES IN WINTER — SOMETHING OF IMPORTANCE TO BEE-KEEPERS.

In England they advertise soft candy for placing directly upon the brood-frames for early spring or winter feeding of colonies where it is thought they are or will be short of stores soon. Several have reported that the ordinary Good candy (probably the same thing), made in 1-lb. lumps, and placed directly on top of the brood-frames, is just the thing to prevent starving. There are those who do not want to bother with making candy, so we have decided to furnish it in pound packages for 15 cts., by express or freight with other goods. The packages are all ready for use. The postal regulations are such that we can not send it by mail. Ten packages will be sent for $1.35, or, in bulk of 10 lbs., $1.20. Fifteen cents, if it saves a colony, is money well invested.

BEES & SUPPLIES FOR IOWA.

Send for my supplement for 1891, now ready (no new catalogue). Say whether you have my catalogue dated 1889 and 1890. Address *Oliver Foster*,

Maple Sugar and The Sugar-Bush

THIS IS A NEW BOOK BY

PROF. A. J. COOK,

AUTHOR OF THE

BEE-KEEPER'S GUIDE, INJURIOUS INSECTS OF MICHIGAN, ETC.

The name of the author is enough of itself to recommend any book to almost any people; but this one on Maple Sugar is written in Prof. Cook's happiest style. It is

PROFUSELY ✳ ILLUSTRATED,

And all the difficult points in regard to making the very best quality of Maple Syrup and Maple Sugar are very fully explained. All recent inventions in apparatus, and methods of making this delicious product of the farm, are fully described.

PRICE: 35 Cts.; by Mail, 38 Cts.

A. I. ROOT, Medina, Ohio.

Wire Cloth.

For door and window screens, tacking over hives and nuclei for shipping, making bee and queen cages, and a variety of purposes. We have the following list of green and black wire cloth which is not exactly first class, but is practically as good for the purposes mentioned, and at prices MUCH BELOW the ordinary price. You can no doubt select from this list a piece to suit your needs Price in full pieces, 1¾ cts. per square foot. When we have to cut it, 2 cts. In case the piece you order may have been taken by some one else before your order comes, please say whether we shall send the nearest in size, or cut one the size ordered at 2 cts. per ft., or give a second or third choice.

No. of Rolls and Color.	Width, In's.	Length, Ft.	Sq. Feet.	Price of a Full Roll.	Pieces less than 100 ft. long. These figures are the number of square feet in each piece. Multiply by 1¾ cents for the price of piece.

Job Lot of Wire Netting.

CUT PIECES AT A LOWER PRICE THAN FULL ROLLS.

Having bought from the factory, at our own price, five or six hundred remnants, as listed below, we are able to give you the choice of a great variety of pieces at the price of a full roll or lower. Full rolls of netting are 150 ft. long, and when they are cut we have to charge nearly double the full-roll rate, because it is so much trouble to unroll, measure, and cut, and run the risk of having a lot of remnants on hand. No doubt it is in this way that the following remnants have accumulated. It costs a good deal to get all this in shape so we can easily pick out from the lot the piece you want. But to move it off quickly, we put the price down so you can all have a chance at it. Remember, first come, first served. In ordering, therefore, name a second or third choice, or say that we may send the nearest we can if the piece selected is gone. On 5 pieces deduct 5 per cent, on 10 pieces 10 per cent. These remnants are shipped only from here. If any of you want to secure some, and don't want them shipped till later, when you will order something else, so as to save freight, pick out the pieces you want, send remittance with the order, with request to lay by till called for, and we will mark them as belonging to you. We prefer to ship them right out, however.

LIST OF POULTRY-NETTING REMNANTS.

Width in in's.	Size of Mesh.	No. of Wire.	Cts. p'r Sq. Ft.	Length of each piece. Multiply by the width in feet to get the number of square feet in each piece. Then multiply by the price per foot for the price per piece.

7	9 " " " "	50	2 25	12 00

About two years ago we bought 150 dozen of above shears, and they have gone off like "hot cakes"—so much so that we have just bought another lot of 350 dozen, which are, if any thing, nicer than the other lot, most of which are gone. The others pleased so well that we got repeated and increased orders from the same parties. Neighbors of those who were fortunate enough to get a pair, on seeing them and learning the price, wanted a pair, and so the orders kept repeating themselves. We are always glad to give our customers a bargain which gives more than satisfaction, and this is one of them. You will see we have made special prices in quantities, and no doubt some of you can do a good thing for yourselves, as well as your neighbors, in getting a quantity and introducing them. They are put up ½ dozen in a box, and we can not assort ½ dozen; but we can give you larger lots assorted, ½ dozen of a kind.

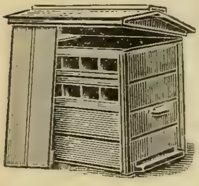
ADVANCED BEE-CULTURE;

Its Methods and Management.

I am now engaged in writing and printing a book that is to bear the above title. It is to take the place of my other book, *The Production of Comb Honey*, which will not be re-published. Although the new book will contain at least five or six times as much matter as *The Production of Comb Honey*, yet the price will be only 50 cts. The book is already partly printed, and will probably be out some time in April or May. If any of the friends would like to "help me along" in meeting the expenses of getting out the book, they can do so by sending their orders in advance. Such orders will be most thankfully received, and filled the *very day* the book is out. I will send the REVIEW one year and the book for $1 25. The REVIEW will be sent on receipt of order (I have plenty of back numbers to send it from the beginning of the year), and the book as soon as it is out. Stamps taken, either U. S. or Canadian. 10tfdb

W. Z. HUTCHINSON, Flint, Mich.

☞In responding to this advertisement mention GLEANINGS.



DOWN THEY GO!

For the next few days $1.25 will buy our 8-frame chaff hive, with 2 T supers and 8 heavy top-bar brood-frames.

Send for PRICE LIST.

ROE & KIRKPATRICK,
Union City, Ind.

☞In responding to this advertisement mention GLEANINGS.

DON'T READ THIS.

For if you do you will send to R. E. Smith, Tilbury Center, Can., for your tins. I wish to say that we are making all kinds of tinware used by the bee-keeper. Honey-extractors of all sizes to suit Jones and L. frames, or to order. 60-lb. square tins. Also a large number of honey-pails, holding from 1 to 10 lbs., with bails. We are prepared to furnish bee-keepers of Canada with

ALL STYLES OF HONEY-CANS

this season of 1891. No. 1 tin used in all these goods. Send for price list of 1891, now out.

R. E. SMITH, Tilbury Center, Can.

☞In responding to this advertisement mention G

OAK HILL POULTRY FARM.

The home of the best general-purpose fowl for the farmers and the fanciers, the **Barred PLYMOUTH ROCKS.**

This year, as in the past, I will devote my five large coops to Plymouth Rocks only, and try to fill all orders promptly from first class stock.

Eggs at $1.50 per 13, and $1.00 for each additional setting in the same shipment. 6d

E. J. KENNEDY, Troy, Pa.

☞In responding to this advertisement mention GLEANINGS.

Cash for Beeswax!

Will pay 25c per lb. cash, or 28c in trade for any quantity of good, fair, average beeswax, delivered at our R. R. station. The same will be sold to those who wish to purchase, at 31c per lb., or 35c for *best selected wax*.

Unless you put your name *on the box*, and notify us by mail of amount sent, I can not hold myself responsible for mistakes. It will not pay as a general thing to send wax by *express*.

A. I. ROOT, Medina, Ohio.

SILVERHULL BUCKWHEAT

for seed. Free from all foul seeds. This buckwheat will outyield the Japanese.

YIELDED FORTY BUSHELS PER ACRE HERE

the last season. This buckwheat is profitable to sow for bees alone, to say nothing about the crop. Delivered on board cars here, in new grain-bags, at $1.00 per bushel. No order taken for less than two bushels. **EZRA G. SMITH, Manchester, Ontario Co., N. Y.**

In responding to this advertisement mention GLEANINGS.

HAVE YOU READ MY

Ad. on **Inside Back Cover** of Gleanings, Feb. 1st? Also my ad. on **Page 117,** Feb. 15th **Gleanings,** about my **New Potatoes?** If not, do so at once. W. Z. Hutchinson, on page 45 of the Feb. *Review*, says, "They would almost **pass for a Sweet Potato."** If you intend to try them it is necessary for you to **order soon,** as they would not go half way round to the readers of Gleanings. Potatoes will be sent the first week in April. Safe arrival guaranteed. 5tfdb

Jacob T. Timpe, Grand Ledge, Mich.

HONEY COLUMN.

CITY MARKETS.

SAN FRANCISCO.—*Honey.*—Since the last rains, the outlook for the coming crop is more flattering. However, we do not expect to see as large a crop as in the previous year. We now quote: Extracted honey, 5¾@6c. Comb, 2-lb. frames, 9@13; 1-lb., 10@15. *Beeswax*, 23@24.

SCHACHT, LEMCKE & STEINER,
Feb. 24. San Francisco, Cal.

ALBANY.—*Honey.*—Comb honey selling quite freely, and stock on hand getting quite small. Have received one consignment of comb honey since last issue. The demand for dark extracted honey is good. There is not quite so much call for light. *Beeswax* very scarce. We quote clover, 15@16c; buckwheat, 12@13. Extracted light, 8@9; dark, 7@8.

CHAS. MCCULLOCH & CO.,
Mar. 10. Albany, N. Y.

NEW YORK.—*Honey.*—Our market is bare of comb honey, and but little demand for any. California extracted is in good demand at from 6¾@7¼c a lb., and the market is well supplied with same. Extracted buckwheat is selling at from 7@7½c a lb., and stock scarce. No Southern at present. *Beeswax*, 25@27c. HILDRETH BROS. & SEGELKEN,
Feb. 26. New York.

DETROIT.—*Honey.*—Comb honey is quoted at 14@15 cts.; sales slow. Extracted, 7@8c. *Beeswax* firm at 27@28c.
Bell Branch, Mich., Feb. 19. M. H. HUNT.

ST. LOUIS.—*Honey.* Market unchanged; have had several inquiries for large quantities, say 15,000 lbs., extracted and strained. Prime *beeswax*, 27c.

D. G. TUTT GRO. CO.,
Mar. 9. St. Louis, Mo.

MILWAUKEE.—*Honey.*—The demand for honey is very moderate; supply of all kinds fair. One-pound sections, best, 18@19; good, 17@18; fair, 15@16; dark or old, 10@12. Extracted white, in barrels and half-barrels, 8½@9; same, in tin cans, 8½@9; dark, in barrels and kegs, 6½@7½. *Beeswax* wanted at 28@30c. A. V. BISHOP.
March 6. Milwaukee, Wis.

CHICAGO.—*Honey.*—Stock is not large, and for the best white comb in desirable shape there is a steady demand at 17@19c; any thing off in appearance is slow at one to two cents less. Extracted, steady at 7@8. *Beeswax* 27c. It is time now that all comb honey were on sale. R. A. BURNETT,
March 8. 161 So. Water St., Chicago, Ill.

FOR SALE.—600 lbs. white-clover and basswood honey, in 60-lb. cans; 10c, f. o. b. F. G. FENTON,
Box 221, Bluffton, O.

FOR SALE.—"Choice orange-blossom" extracted honey in 60-lb. tin cans, or kegs holding 14 to 15 gallons. Price $1.25 per gallon, f. o. b. cars here.

ARTHUR F. BROWN,
6 9db Huntington, Putnam Co., Fla.

FOR SALE.—1200 lbs. extracted white-clover honey in barrels or 60-lb. cans, as desired.
1tfdb E. J. BAXTER, Nauvoo, Ill.

FOR SALE.—Choice honey in sections, cans, and C. pails. Send for price list to OLIVER FOSTER,
12-tfdb. Mt. Vernon, Ia.

FOR SALE.—120 lbs. choice clover honey, in 20 lb. cases. F. H. MCFARLAND, St. Albans, Vt.

Bee - Keepers' ✻ Supplies.

I WILL GIVE 10 PER CENT DISCOUNT

on all orders received during March. Don't wait until the busy season before **ALBINO** you order your queens, for it sometimes causes delay. 6d
A. L. KILDOW, Sheffield, Ill.
Please mention this paper.

$5.00 IN MAY, AND $4.50 IN JUNE,
—WILL BUY—
A Strong Full Colony of Pure Italian Bees

in Root's new Dovetailed or the old Simplicity hive, as you prefer. Each to contain a fine tested queen and plenty of bees and brood. Everything first-class. Pure Japanese Buckwheat, per bu., $1; ½ bu., 60c; ¼ bu., 35c, bag included. Scotch Collie Pups, $4 each.
N. A. KNAPP, Rochester, Lorain Co., O.

GLEANINGS IN BEE CULTURE

A JOURNAL DEVOTED TO BEES AND HONEY AND HOME INTERESTS

Published by A. I. Root, Medina, O.

Vol. XIX. **MAR. 15, 1891.** **No. 6.**

STRAY STRAWS

FROM DR. C. C. MILLER.

DON'T YOU LONG to see the bees at work?

THE TRADE-MARK isn't booming so much.

THE *Review* wants no trade-mark. Right, Hutch.!

ISN'T THAT a neat engraving at the top of the page?

HON. EUGENE SECOR is re-elected President of the Iowa State Horticultural Society.

HOW TO GET a stand of melilot might be a good subject for experiment at Michigan Agricultural College.

J. H. LARRABEE, a live bee-keeper from down east, has been chosen to help Prof. Cook in his apicultural experiments.

THE CALIFORNIA BEE-KEEPER is out—Vol. I., No. 1. It *ought* to live—gotten up in fine shape, and the salutatory has the right ring to it.

"STORIFYING" is what our English cousins think we ought to say instead of "tiering." I'm afraid they're right. "Piling" might do.

"NET WEIGHT ONLY" marked on the end of the case, says Henry Segelkin (GLEANINGS, p. 133). Please tell us why only net, and why on the end.

A NEW SMOKER, by A. G. Hill. Looks a trifle like a Bingham upside down. Has the advantage that it is always right side up, whether in use or idle.

PROMINENCE is to be given just now at Michigan Agricultural College to experiments in wintering, improvement in bees, and planting for honey.

OLD KEROSENE-CANS, says the *California Bee-keeper*, should *not* be cleaned out for honey. Just leave them dirty, and then fill them up with—kerosene.

"If God has made this world so fair,
Where sin and death abound,
How beautiful beyond compare
Must Paradise be found!"

AN EGG IN A CELL stands up straight the first day; second day at an angle of 45°; third day, it lies flat on the bottom of the cell. I learned that from Cowan's new book, "The Honey-Bee."

GEO. F. ROBBINS writes that he has tried it, and knows that enameled cloth is better than painted muslin for hive-covers. He puts the enamel side down and then paints it. It doesn't take one-third as much paint as muslin. Still, tin is good.

GOOD FOR WISCONSIN! Here's a resolution at their State convention: "That this Association send one delegate to the next American Bee-keepers' convention, and pay $10 toward his expenses."

PUTTING BEST PREMIUMS on light honey, and little or nothing on dark honey, is scratching out our own eyes. So says Hasty in an article in *American Bee-keeper*. The whole article is excellent.

IN HAULING BEES or honey in day time, A. N. Draper tells in *A. B. K.* about loading up close to the hives, and, by means of a 40-foot rope, hauling the wagon some distance before hitching on regularly. Good idea.

LINDEN-TREES are among the most desirable for shade on the streets. Wouldn't it be a good plan to give them away to be planted on the villags streets?—cheaper than to plant them on your own ground, just as good for you, and a kindness to your neighbor.

WHAT SECRETIVE PEOPLE those Michiganders are! There's Prof. Cook. It was darkly hinted that the government was doing something for the benefit of bee-keepers, and now Hutchinson brings out the fact that an experimental station is started, with Prof. Cook as chief engineer—a grand choice.

GERMAN BEE-KEEPERS are all stirred up over the matter of *heating* in winter. Its leading advocate, Pastor Weygandt, is considered by one party as an investigator to be placed alongside of Dzierzon, while the other party looks upon him as an idle dreamer. Details as to carrying out his plans are so indefinite that at present we can only wait to see what others do.

PROF. COOK says he wants suggestions as to subjects for experiment, also as to the manner of conducting experiments. Wouldn't it be a good plan to snow him under with suggestions? Out of the lot he ought to get some that would be usable. With such men as Cook and Larrabee at the helm, it's a pretty sure thing that the experimental station will be in close touch with the rank and file of bee-keepers.

NO SWARMING will generally take place, says Dr. Tinker, in *A. B. K.*, "if at the beginning of a honey-flow we take an empty story with foundation starters in the frames, and put on the excluder, then a super of sections for storing, and the brood-chamber of any colony ready to work in the sections on top of all. The queen, of course, is to be put below the excluder in the new story." In 1889 I tried a number of colonies on this plan, but failed. Possibly the season was too poor.

"THE DOUBLE-COLONY" plan, as he calls it, is given by G. W. Demaree in *A. B. K.* In brief it is this: When a colony swarms, remove its queen and put it in a brood-chamber on the old stand, with empty combs, except one comb of honey in which a queen-cell is grafted, on this a queen-excluder, and then a second story with the brood-frames and queen-cells, and then the surplus cases. The queens above will be destroyed before or after hatching, and the young queen below remains reigning. Won't the bees sometimes desert that single cell?

A NEW STUPEFIER is described in *Leipziger Bienenzeitung*. It is kept by supply-dealers, put up in little bottles, and, under the rather inappropriate name of "laughing-gas," consists of solid white crystals the size of coffee grains. Its fumes act like magic in immediately producing apparent death, and, as magically, life is restored, with no trace of effect, except that all memory of the past is gone, allowing change of queen, change of locality, uniting, etc. But disastrous results weeks, and even months afterward, are charged to its account.

GET READY for a big crop. If you're ready for it and it doesn't come, there's no great harm done. If you're not ready and it does come, then there is harm done. You'll get all in a stew right in the middle of harvest, and, instead of being just running over with gratitude for having such a big crop, you'll grumble at the supply-dealers because they don't start your supplies on the road about two hours before you mail your order, snap up your wife when she asks you to stop long enough for dinner, and make yourself such a nuisance generally that you'll want to get away from yourself. Get ready in time.

GENERAL CORRESPONDENCE.

BIOGRAPHICAL.

WHO IS RAMBLER?

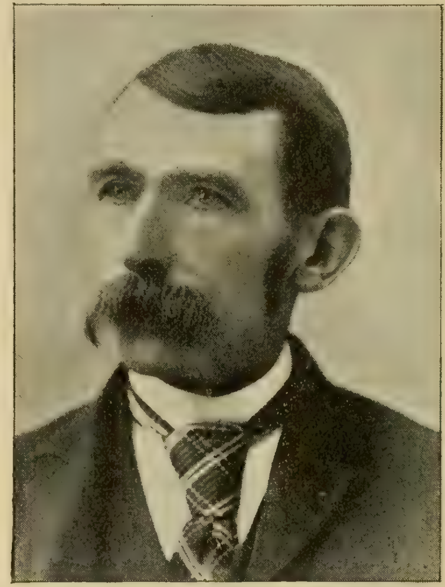
The subject of this sketch was born in the town of Hartford, New York, Dec. 30, 1839. His grandfather came from the State of Massachusetts, and was one of those hardy Puritan pioneers who settled in that region near the close of the last century, and there carved comfortable homes from the virgin forest. He was a man of high native qualities and Yankee shrewdness, and from him John H. seems to have inherited his full share. As John was an only son he was given good educational opportunities, spending some time at a neighboring academy, and at the Fort Edward Collegiate Institute.

In 1868 he married Miss Libbie C. Edwards, who died in 1881, leaving no children. She was an estimable lady, and her death was a great loss to the community.

For many years Mr. Martin followed agricultural pursuits on his father's farm; but owing to a somewhat frail constitution, and the death of his wife, followed, in 1883, by the death of both his parents, he gave up the farm entirely; and bee culture, which had formerly been a side issue, was given all his time and attention.

His grandfather was the first to introduce into that section the Weeks patent hive, which at that time was a great improvement. By observing his grandfather's bees and methods, he early became interested in the bees, and hence he can hardly tell when his career as an apiarist began. As early as 1874 we find him with 55 colonies of bees, and a contributor to GLEANINGS. Since that time his apicultural career has been plainly indexed by his contributions to this paper. Since he has devoted all his time to the bees, it has been his method to keep from 200 to 300 colonies, running them for extracted honey, and doing all the work himself, except during the extracting season. At present his colonies are somewhat reduced, owing to the past successive poor seasons and bad winters. One season his crop was 16,000 lbs. of honey, and his average for the past 12 or 15 years has been about 7000 lbs. of extracted honey per year. Since the advent of the Heddon hive he has adopted it and its methods, and the chaff hives and outdoor wintering are being discarded.

Mr. Martin is a thorough student of the bee, as the many bee-books, old and new, and bound volumes of the bee-periodicals to be found in his bookcase, all show. He is also a superior workman in wood, and very ingenious in the invention and application of apiarian implements. The old homestead, where he now resides with kind friends, is a most beautiful spot. A broad turnpike leads up from the village, and for some distance there are, on either side of the road, rows of thrifty basswoods, planted years ago by Mr. Martin's own hand. The house is a typical Eastern homestead, large and square and white, among venerable maples. Just beyond the house is the apiary with its high lattice fence and arbor of grapevines, while all around are the high hills and broad valleys of an excellent honey location.



THE RAMBLER.

In person Mr. Martin is quite tall and slender; there is not an ounce of spare flesh about him. In manner he is very modest and quiet, yet continually, through his eyes and in his words, one sees the humor of the man. He has great love of the quaint and humorous side of humanity, yet his humor never offends by its coarseness nor galls by its acidity. The series of articles written during the last two years, under the *nom de plume* "Rambler," has made him well known to all the readers of GLEANINGS. His method of combining the entertaining and the instructive in a manner to make it read by all is very characteristic.

Mr. Martin is a true Christian—very zealous in Christian work, and is a leading member and deacon of the Congregational church of his town. He has long served as superintendent of the Sabbath-school; and in all matters pertaining to the spiritual and temporal welfare of the society his influence is felt, and is always on the side of right. JOHN H. LARRABEE.

Ag'l College, Mich., Jan., 1891.

[You have given us an excellent sketch of our "mutual friend," and your next to the last paragraph describes his personality almost exactly. Along on my bicycle tour I was frequently asked, "Who is that Rambler? I like his style, anyhow. But I want to know when that chap is coming around to visit me, so I can kind o' slick up, you know." I was asked so many times about Rambler's identity, that, when I reached Lake George, I told Mr. Martin that it might not be a bad idea for him to let his real name be known, now that we had abundant evidence that his Rambles were appreciated and sought after by thousands of readers. Dr. Mason once said to me, "Ernest, I don't like this *nom-de-plume* business. Now, there is Rambler—a rather nice fellow, I judge, but I should like to know who he is; and when he gives me a 'blackboard exercise' I can give him another in return." Again, at the Albany convention, I think it was Charles Stewart who said to me, "Rambler is John H. Martin, is he not?"

"Yes, sir; how did you know?"

"He referred in one of his letters to his horse 'Nig,' and then I knew his identity at once."

Later.—Rambler is now going to California, and our readers will get the benefit of his western rambles. See his advertisement elsewhere.] E. R.

CONDUCTIVITY OF HIVE-WALLS.

EXPERIMENTS TO ASCERTAIN THE COMPARATIVE RESULTS BETWEEN THEM.

With a view to test the relative conductivity of different hive-walls I recently spent about a week in conducting experiments, and in making preparations for them.

The hives used were eight-frame Langstroth. No. 1 was a single-walled hive, made of scant ⅞-inch lumber, sent to a neighbor as a sample hive from the factory of Mr. Heddon. Nos. 2 and 3 were half an inch wider, and one-eighth inch longer inside. Both of these were double walled, with 1¾ inches for packing. The outer walls were plump ⅜ inch, ship-lapped, and lined with one thickness of building-paper to keep the wind from driving in through the joints. The inside walls were composed of picture-backing, say about $\frac{3}{16}$ inch thick. In No. 2 the walls were firmly packed with cut straw, such as is used for fodder, and in No. 3 they were packed with granulated cork.

The bottoms were removed. In order to cause the cooling to take place as much as possible through the sides, each hive was covered with two cushions of wool tacked down with strips, the cushions weighing together 29 oz. There was a difference of only half an ounce in the weights of the three covers. To prevent the escape of heat as much as possible downward, similar cushions were fastened on the under side of the bottoms.

The first step was to verify my thermometers. I tested five instruments simultaneously, and, as it happened, the variations were so slight that, in experiments of this kind, they might be ignored. When every thing was ready, a tin pail containing 7½ lbs. of boiling water was set on each bottom-board, and the hives set over them. The thermometers were then inserted through slits in the quilts, so that the bulbs extended into the water. After the mercury began to fall in each instrument, readings were recorded every half-hour for ten hours and thirty-five minutes. At the end of that time the temperatures, which at the first reading were 170, 171, and 175°, had dropped to 40, 48, and 58° respectively. It was noticeable, that at first the thermometer indicated higher in the single-walled hive than in either of the others, the heat in the latter being absorbed, I presume, in warming up the thicker walls.

It would, perhaps, be interesting to the reader to be able to examine the record of the readings in detail, but it would take up considerable space.

The outside temperature during the time the readings were taken averaged about 1° below 0. The following figures show the times of cooling down 100°:

Single-walled hive	330 min.
Straw-packed "	450 "
Cork-packed "	459 "

When this experiment was finished, I was not satisfied with the result. The double-walled hives did not stand close on the bottom-boards. I tried to fill up the cracks with oakum; but with a wind blowing, and a zero temperature, a very slight crack would vitiate the result; so I resolved upon another trial.

In the second experiment I fixed up the bottom-boards so that they would hold 2½ inches in depth of dry wood ashes, this being a very good non-conductor of heat. On these beds the hives were placed, and pressed down so that they were comparatively air-tight at the bottom. In this case the bulbs of the instruments were not placed in the water, but extended below the covers about two inches. During this experiment the outside temperature averaged about 10° above 0. The times of cooling down through 65° were as follows:

Single-walled hive	390 min.
Straw-packed "	460 "
Cork-packed "	475 "

In this experiment I found that, having the hives close together, affected their rate of cooling perceptibly, from which we may infer that, by placing hives close to each other in clamps, cellars, etc., they will keep warmer than when a greater distance apart. I thought, too, that, after all, keeping the bulbs in the water gave safer indications of the rate of cooling, so I determined to try it over again once more.

In the third experiment the hives were placed on beds of ashes as before; but I now packed soft wet snow around each hive, and crowded it up against the walls every hour to prevent air-spaces forming. The bulbs of the instruments were placed in the water as in the first case. This experiment I regard as the most reliable of the three. The times of cooling down 75° were as follows:

Single-walled hive	503 min.
Straw-packed "	570 "
Cork-packed "	675 "

When Count Rumford made his elaborate experiments on the conductivity of materials used in clothing, about 100 years ago, his method was this: "A mercurial thermometer was suspended in the axis of a cylindrical glass tube ending with a globe, in such a manner that the center of the bulb of the themometer occupied the center of the globe; the space between the internal surface and the bulb was filled with the substance whose conductive power was to be determined. The instrument was then heated in boiling water, and afterward, being plunged into a freezing mixture of pounded ice and salt, the times of cooling 135° were noted."

My experiments were imperfect in this respect: Although the hives had been kept over night in the kitchen, there was a great difference between their temperature and the temperature of the water placed in them. Owing to the difference in the material and thickness of the walls, the amount of heat absorbed by the walls in each case was not the same. If I could have placed the whole lot in a large oven, so as to heat all the materials to the same degree, as was done in Rumford's experiment, the result obtained would have been more reliable. As it is, however, the experiments give some indications of the comparative warmth of the different hive-walls. S. Corneil.

Lindsay, Ont., Feb. 20.

[Friend C., we are very much obliged indeed for the report of your valuable experiment. I wish, however, you had placed a similar pail of water right outdoors, without any protection; then we could have told just how much any sort of protection amounts to. Another thing, a colony of living bees giving off moisture from their respiration requires a covering somewhat different from that needed to preserve a vessel of hot water or a cake of ice; that is, the arrangement that would hold the heat longest for the brick or the ice would not be exactly what we need for a cluster of living bees. Your experiment demonstrates very clearly, however, the advantage and the protection that chaff and cut straw afford to a colony of bees during severe weather.]

FIXED FRAMES.

AN ILLINOIS MAN DISCUSSES SOME OF THEIR FEATURES; HE CAN HANDLE THEM FASTER THAN THE UNFIXED FRAMES.

Friend Root:—The discussion that has appeared in Gleanings in the last six months in regard to the different frames used in hives should interest every progressive bee-keeper, since Ernest's visit to the East; and he there found a majority of the bee-keepers using a fixed-frame hive. It has aroused an inquiry in the minds of many of the bee-keepers of the South and West: Does the fixed frame possess advantages with which we are unacquainted? and have its disadvantages been exaggerated? The discussion has, I think, disclosed the fact that there are more using a fixed-frame hive than was generally supposed—not from mere choice, but because they were convinced, after trial, that it possessed advantages not found in the hanging or adjustable frame.

I believe it is generally conceded, that, in the fixed-frame hive, there is less burr-comb built than in the hanging frame, especially between the hive and super; that it possesses superior advantages when hives are hauled on wagons to out-apiaries or distant fields to take advantage of honey-flows not existing in their own neighborhoods. The frames being fixed, they are ready to load on the wagon without having to stop and fasten them in the hive by some device, and then unfasten them on arrival at destination.

The disadvantages claimed for the fixed frame are, that they can not be manipulated as fast or as easily as the adjustable frame; but when Ernest saw some of the prominent bee-keepers of the East handle fixed frames easier and faster than he could the loose frame, he was convinced that the disadvantages claimed for it in this direction had been greatly overrated, and so I think.

I have been experimenting with hives for 12 years, having tried most of the different styles that have laid claim to popular favor, being desirous of obtaining the best hive invented. Having tried many of them, I will say that I can handle a fixed-frame hive, invented by Mr. Armstrong, of Jerseyville, Ill., who is now out of the business, with greater ease, and faster, than I can any loose-frame hive that I am acquainted with. But I have settled on a shallow fixed-frame hive, brood-frame 5 inches deep. Two cases filled with these frames make a brood-chamber. Here we have nothing but white clover to depend on for surplus, and it is gathered in from two to five weeks. Now, in order to get through the honey-harvest with as few unfinished sections as possible, we must devise some plan to keep the bees at work in the sections from the time they commence until they are finished; for if we allow them to stop, which they usually do when they swarm, the harvest is likely to be over before the sections are finished. Now, in order not to have the bees stop work in the sections when they swarm, I move away the hive that has swarmed, and in its place I set one case of the shallow hive; put on a queen-excluding honey-board and the supers from the hive that has swarmed; then run the swarm in the new hive. The brood-chamber being so shallow, the bees are forced up into the sections; the work goes on, and the sections are completed without delay. In four or five days the queen-excluding honey-board can be taken off, if desired. The queen will not go above in the sections. If, when the sections are about completed, there is not time to finish another lot, raise up the super and insert, between it and the brood-chamber another section of the brood-chamber, which the bees can proceed to fill for winter stores, or it can be extracted.

While the plan above is not new or original, yet I think it worth repeating, as we sometimes have to read a thing two or three times before we think there is any thing in it.

Delhi, Ill., Feb. 5. H. D. Edwards.

[Yes, it appears that there are more using fixed frames than was generally supposed, and that, too, when most of the books and journals for years have declared against them. Now that the tide is changing, the fixed-frame users will increase greatly, but the loose frame will continue to be used largely yet. See page 224.]

R. F. HOLTERMANN ON A VISIT.

HE CALLS ON MR. ALPAUGH.

A visit to the home and apiary of Jacob Alpaugh, St. Thomas, Ont., could not result in any thing but material gain to an observing bee-keeper. On every hand we find ingenious contrivances to lessen labor, and to do work in a better manner. To assure the readers of Gleanings that these inventions are practical, I need only to mention that they are in use by Mr. Alpaugh and others, and that Mr. A. intends running five apiaries the coming summer, and has at present 370 colonies, 190 of them in the cellar, the remainder wintering on their summer stands. The bees wintered on their summer stands are packed four in a box, two entrances at opposite sides. They are packed with forest-leaves, no packing at the bottom; at the top, a fresh quilt and about eight inches of forest-leaves; the entrance is left open to the extent of about eight inches. A few colonies are being experimented with for the second year, the first having been an entire success. An empty story is placed between the bottom-board and the body of the hive; an entrance is left in each; an eight-inch packing of forest-leaves is put above the body, with bees in it. A new quilt is, of course, put above the bees. No further protection is given to the bees. Of course, we have had several mild winters, and it would hardly be advisable to adopt this plan generally at present.

In order to give the method of cellar wintering, the cellar must here be described. It is 18x11 feet and 6 feet high. The walls have no connection with the outside. The entire cellar is inside of another 30x25-feet wall made of stone 16 in. thick, and with a cement floor, the latter common to all. The inner compartment has for its walls half-thickness brick. The ceiling is boarded with matched lumber against the joists. The air, hot or cold, can, therefore, pass clean over and about the inner repository, all but the floor. Two ventilators pass into the inner cellar. One, 4x8 inches, is attached to a chimney; the other, 4 x 4 inches, passes up through the center of the house. Both generally draw air from the top of the cellar; but by adding a length to the pipes they can be made to draw from the bottom. A door connects the inner repository with the outside cellar. Either wire or solid wood can be used. So far this winter the screen only has been used. The main cellar is further ventilated by means of a door at one side, and on the opposite side a window. The door to the inner repository is between the door and window of the outer, giving a free current to the bees when desired.

There is another compartment which contains a large stove, used as a furnace. From this the air around the inner repository can be heated to any desired temperature. The only difficulty, Mr. Alpaugh says, is when the outside temperature gets too high. The bees are packed almost solid, four tiers high. The bottom tier is about four inches from the floor, and this tier has an inch rim between the body and the bottom-board. The greatest number of colonies ever wintered here was 260, and the temperature has been as high as 60°, seldom as low as 50. No trouble has been found in regard to spring dwindling, and there were not enough dead bees to cover the cellar floor up to the time of my visit, Feb. 7. We raised the quilt of one colony. The bees were as small as in summer, bright and clean. They certainly were not hibernating, however. The 190 colonies made a slight hum, but one could scarcely detect the odor of the bees—a very good indication of a healthy condition. I feel satisfied that the bees go into winter quarters in good condition. Of course, this is a great step toward successful wintering. I have for years felt that Mr. Alpaugh had a very fine cellar for wintering bees; and the only addition I might advise would be a spring of water to assist in keeping down the temperature in spring.

In a future number I propose describing a few of Mr. Alpaugh's inventions in the bee-line; and as your readers may be interested in one or two contrivances about the house, not in connection with bees, I shall take the liberty of briefly describing them, especially as I know you have a weakness for pure water. The cistern, or tank, for soft water stands on the floor of the main cellar. It is 6 ft. in diameter and 6 ft. high. The water is caught from the roof of the house and pours into the top of the tank. The overflow pipe draws the water from the bottom and communicates with the house-drain. A tube connects with the overflow-pipe, just where it bends over the tank. This tube carries all foul air from the drain to the chimney, joining the kitchen stovepipe, I believe. The water in the tank, by means of the above, and being quite open at the top, is pure, and used for drinking, frequently; so, Mr. Root, when you go to Alpaugh's you will find waiting for you soft water as well as a soft bed.

MR. ALPAUGH'S DEVICE FOR DRAWING WATER.

I was attracted in the woodshed by a wire-cloth trap-door covering a box. Asking what it was I found it covered the box upon the well-platform; and immediately above it, and suspended to the rafters of the shed, was a wooden roller with two light ropes attached. I knew Mr. Alpaugh could afford a pump, but I received the following explanation: "I believe that every well should be so arranged that the air has full access to the water. That is why I have the pump out and the pail to dip; also the wire trap-door. The latter allows a constant free circulation; the former takes a certain amount of fresh air to the water every time we dip, and takes it from the surface at all times. We could not use the water when we had the pump in it; but now, as you can see for yourself, it is very good, for surface water." The above contrivance is to make the drawing of water easy. It consists of simply an eighteen-inch roller, half of it two inches in diameter, the other half four inches in diameter. To the latter a rope is attached, long enough to strike the water and allow the attached pail to sink and fill. The pail is galvanized iron. To one side is attached a weight, so that, when the pail strikes the water, the pail is drawn to one side and fills. The pail rights itself the moment the rope pulls on it. To the two-inch roller is attached a cord half the length of the one attached to the 4-inch, and to this is fastened a weight just the weight of the zinc pail when filled with water; when the weight rolls up, the pail goes down; and when the pail comes up, the weight goes down. So it takes a little pull (you can do it with thumb and finger) to bring the pail down and about the same to bring it up. With a proper catch to clasp the bail of the pail, it is a pleasure to draw water. It is fully as easy as pumping, and the frailest woman can work it without much exertion.

When I think of all the places I visit where they draw soft water, and sometimes hard, by means of a rope or a stick attached to the pail, I feel as if you should turn that simple roller, and have it among your household conveniences, for such it assuredly is. It may be old to some, and to many new. R. F. HOLTERMANN.

Romney, Ont., Feb. 16.

GLOVES—WHAT KIND TO USE.

RUBBER GLOVES NOT SUITABLE FOR BEE-WORK. FINGERLESS GLOVES PREFERRED; DRESS FOR LADIES.

Friend Root: — I, for one, have used rubber gloves in the apiary, but I did not like them. They draw, and burn the hands until one can hardly endure it, especially if the weather is very warm; and when you take them off, your hands will look as if you had been washing in hot suds all day. Another thing is, they are so clumsy in handling frames that one is apt to drop one end of the frame on the hive with a jar, and the result is—mad, stinging bees.

I like my fingers uncovered while working in the apiary; but I prefer the backs of my hands covered. As much as I dislike propolis on my fingers, I would rather endure it than to wear rubber gloves. I like fingerless gloves, and I will tell you how I make mine. Take an old pair of stockings; cut the feet off; cut a small piece out of the sides about two inches from the end where you cut the foot off. This is for the thumb. Take a thread and needle and whip the edge over and over, not too tight; next whip over the bottom so it won't stretch so much; then sew it together in three places; that makes four finger-holes; then run a rubber cord in at the top to keep them up on the arms. The gloves keep the bees from crawling up the sleeves; protect the hands from the sun and a little from stings. I will say *a little*, for the bees will sting through them; but do as in the A B C—that is, slap your hand against your person, and you will suffer very little from stings. They are so easily made, and so inexpensive, that, when one pair gets soiled, you can burn them; or, if one chooses, they can be washed and used again.

I think Miss Emma will find bed-ticking aprons too heavy and warm for summer. They will do very well in spring and fall. Last season I used seamless-sack aprons with large pockets sewed on flat made out of Indian-head factory, also faced around, and belt of the same. I liked them very well, as the honey does not leak through them. I found them pretty warm in June and July. This coming season I am going to try a soft pliable kind of table oil cloth. I don't think paper aprons would do, on account of fire from the smoker. The apron and glove part doesn't bother me as much as the head-dress. I don't like veils or wire-screen hoods very well. They are hard on the hair. Still, by wearing a net or a thin muslin cap to protect the hair, I can get along very well with the hood. I wear one made like Mrs. L. Harrison's with a cape and draw-string at the waist. With this kind of a head-dress, and my fingerless gloves, and my long apron, I think my dress is pretty well protected.

Mrs. W. G. Tittsworth.

Avoca, Ia., Feb. 8.

[As practical and as extensive a bee-keeper as W. L. Coggshall uses fingerless gloves. I never wore any thing of the kind; but if I worked with some of those York State hybrids I should certainly want them. Hello! here is another who prefers fingerless gloves. He writes:]

I noticed an article in your journal about buckskin and other gloves, and I beg to offer a suggestion. I use gloves made like mits, covering the hand nicely, and just letting the ends of the fingers protrude. These are home-made, made of white linen or domestics. The reasons for their use are, they are white; they prevent the sun from burning the hands; are nice to use, and, above all, can be frequently washed, and thus kept nice and clean. If those who use gloves will try those made of two thicknesses, as above stated, of linen or domestics, they will find them vastly superior to rubber, and much pleasanter to wear in every way.

Atlanta, Ga. T. E. Hanbury.

A HIVE.

DR. MILLER HAS GONE AND INVENTED A BEE-HIVE.

"Didn't know I'd been studying up a hive?" Well, now, you listen. It's to "fill a long-felt want." Some people want a hive that is just right for cellar wintering—a single wall, with nothing inside but the frames—precisely the one I'm talking about. Some want a hive with a dead-air space, light enough to be easily handled. Mine's just that. You see, it hits everybody. It's an A 1 affair. I first called it "*The A1 Hive;*" but the "1" seemed so small a number I left that out, and I thought the name still pretty long, and so I dropped the "*The*," leaving the name, "A hive," and then I changed the big "A" to a little "a," so that, when anybody ordered a hive without mentioning any particular name, the supply-dealers would be sure to send mine.

It's a summer and winter hive. I'll tell you about it. An outside body just like the Dovetailed; inside of that, the frames. These are closed-end, the top-bar being closed at each end like the Hoffman. A dummy, or follower, is wedged up against each outside frame. That's for a summer hive.

For a winter hive I have invented a stick in manner and form as set forth, of just such size and proportions as to fit in the spaces between the top-bars. When the harvest is over, these sticks are put in. You will now see that we have a dead-air space all around. At each end of the hive there is a space between the closed ends and the wall of the hive. At each side there is a space between the dummy and the side of the hive. After the sticks are put in, the bees will glue every thing air-tight, leaving a dead-air space between top-bar and cover.

Now, don't you see that here is a hive, warm, light, good for any season of the year? What? "Nothing original" about it? That's just like A. I. Root. Lie awake nights thinking up a big thing, only to be told it's "nothing original." Well, anyhow I'd like to know who invented those sticks in manner and form as hereinbefore specified.

LAYING WORKERS.

G. B. Replogle has given me his plan of getting rid of laying workers. It is based on the fact that, in a hive containing laying workers, the bees are all old enough to know the way to their hives, no matter where they are put. So, after getting the bees of such a colony to fill themselves with honey, he shakes them down in front of a colony containing a laying queen. Being filled, they are received all right; but on their first flight they will return to their old location, where a caged queen may be given them. The laying worker or workers will not fly out, but will be killed. The plan is ingenious, and I don't see why it won't work. I should think some of the bees, at least, would be so much better pleased with their new quarters that they would mark their location on their first flight, and not return to the old place. But there would be no great harm in that.

FIXED FRAMES AND CLOSED ENDS.

The matter of fixed frames and closed-end frames has been pretty thoroughly discussed; but some of us old fogies are a little anxious yet, for fear we shall be driven with the current into some place we don't want to go. There is no question as to the desirability of having frames always fastened in the hives, if we can have the advantages with no accompanying disadvantages. The prominent question that comes up in my mind is this: "Can frames that touch together throughout the whole or a part of their end-bars be handled as rapidly without killing bees?" We are asked to believe that we can, and yet—and yet. Does it look reasonable? Of course, I have confidence in the word of those who say they can; but, have they tried fairly both ways? I may be asked why I didn't try both last summer. I did intend to, but failed to get the frames made at either of two principal establishments to which I applied, and had not time to make any myself. I am not a good hand to make experiments, for in the busy season I am worked to the limit of my time and strength, with little time for any thing but straight work.

Assure me that fixed closed-end frames are not bee-killers, and I think I am "fixed." But if the Hoffman frame, with the end-bars touching part way, kills no bees, why not go the whole figure and have the frames come together everywhere except that part of the top-bars which is directly over the comb? That would allow no bees to get on the outside part of the frames unless they entered at the bottom of the frame-ends. In that case it seems to me there would be no glue on the outside of the frames unless at the bottom of the end-bars.

On page 87, G. F. Robbins asks that there be only $\frac{3}{32}$ of an inch play between the end-bars and the end of the hive, and E. R. replies, "No, it would not do to leave the usual ¼ inch between the closed ends and the end of the hive." You may be right, but please tell us why. With any thing less than ¼ inch you can count for a certainty on having the lower ends of the end-bars thoroughly glued to the hive.

In days gone by, the insuperable objection supposed to be against fixed distances was that combs were not all alike, and fixed distances would thoroughly prevent interchanging. A. E. Woodward brings up the same objection as the result of experience (page 96). I must confess I don't now believe there's much in it. How much advantage do the loose hanging frames really have? How much difference do we make for inequalities of combs? I must own that I don't pay any attention to them, and I doubt whether others do. I try to space the top-bars equally; and if I succeed perfectly in my endeavor, they are spaced precisely as they would be with Hoffman or closed frames. The only difference would be, that, with such frames, I could do easily and quickly what I can do only imperfectly with loose frames, even after spending much time at it. C. C. MILLER.

Marengo, Ill.

[Well, doctor, I have been studying your hive pretty carefully, and for the life of me I can not tell whether you are in earnest or whether you half mean what you say. There are some good things about your hive, fooling or no fooling. I know it is cruel to say so, but this method of plugging up the spaces between the top-bars with suitable sticks was suggested by some brother a year or two ago in GLEANINGS; and, if I remember correctly, he has put the thing in practice, and says it is all O. K. But, doctor, there is a better way than that. Throw away the sticks, and lay an enamel cloth on the frames, and the bees will seal it down tight, and you will have your dead-air spaces and all—see?

The reason we do not want a bee-space back of the closed ends, or, rather, between the closed ends and the end of the hive, is to prevent the bees from getting *behind* and propolizing in the cracks on the *back* of the uprights, etc. You see, if these uprights are thick enough to fill up this space, and yet leave sufficient play to be readily removable, the bees can propolize them where they come in contact on *the inside only*, and you will see this would make quite a difference in their mobility.

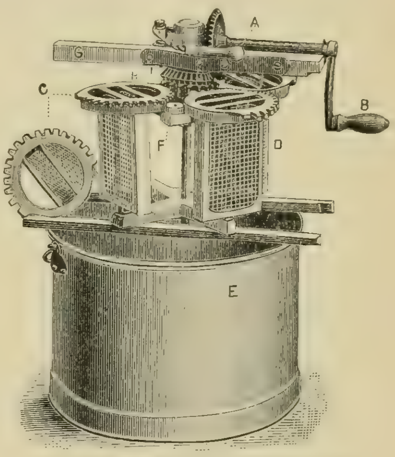
As to fixed frames not being interchangeable, there are only two that I know of who have urged this as an objection. I questioned very closely the York State bee-keepers—prominently, Elwood and Hoffman—on this very point; viz., whether fixed distances prevent the frames from being alternated or interchanged from one part of the brood-nest to the other. They hardly knew what I meant; and when I questioned them further they said they had experienced no such trouble. Closed-end frames on the Quinby plan will not kill bees—in fact, not as much so as ordinary loose hanging frames in wood rabbets. I know some of you will be somewhat surprised, but nevertheless this is a fact. Mr. Elwood will shortly explain *why* this is so, in an article, and so I will not attempt to explain.

With the Hoffman frames there will be killing of bees if there be careless or unskillful handling. But Mr. H. himself avoids the trouble, and I think the rest of us can. You know that, when we put a flat cover on a hive, we kill bees if we set it flat down on the square edges of the hive; but with a *sliding* motion, in the hands of those who use that cover, there is not the least excuse for killing bees; and the same thing is true, to a very great extent, in handling the Hoffman frame.] E. R. R.

REVERSIBLE EXTRACTOR.

ANOTHER MACHINE.

As per request, I send you a photograph showing my improvement in automatic reversible honey-extractors, taken from a rough model of my own construction. It will be seen that the mechanism is such that reversing the motion will reverse all the comb-baskets, with positive action. The comb-baskets stand and reverse on a pivot at the center of their bottom end, the top end being held in position and reversed by metal rings having cogs half way or more on and around their outer surface, with large or stop cogs at each terminus of cogs. The rings have a flange all the way around from the base of the cogs downward, which work against anti-friction rollers, as at F on the end of the arms which hold the rings in position. The rings are secured to the comb-baskets in such a way as not to interfere with this flange working on the guide.



LAWSON'S REVERSIBLE EXTRACTOR.

The cog pinions are fastened together and driven by the beveled wheel from the crank, and revolve loosely on the shaft—the lower one, or spur pinion, working in the cogs of the rings, and, when in contact with the large or stop cogs, set the extractor in motion. The comb-baskets with rings can be instantly removed from the machine for cleaning, and just as quickly returned to position. The brake A is very powerful, and will stop the machine almost instantly. It is composed of a drum secured to the top of the main shaft, and encircled with a strap secured to the cross-bar, and tightened with a lever.

This machine is not mere fancy theory, as I have done all my extracting the past season with one of about the same construction, and I can truly say it gave me entire satisfaction, and, in my humble opinion, is the extractor of the future. ALLEN J. LAWSON.

Brighton, Ont., Feb. 3.

[We at first did not see how the rings at the top of the basket were held in position so as to mesh into the gear of the driving-shaft; but we notice the little rollers you speak of as F in the ent. and we have no doubt they will hold the rings in position. Your extractor offers facilities for putting in and taking out the combs, and the action of the reversing would be positive and certain. The extractor will work, no doubt; but we are inclined to think the expense of manufacture would preclude its general use among bee-keepers. So much gearing is expensive; and, besides, the can will be large.]

WAX SECRETION.

DO CIRCUMSTANCES OR THE BEES GOVERN THE SECRETION OF WAX SCALES? ARE THEY EVER WASTED?

Many writers for our bee-journals, and some of them our most cautious and able bee-keepers, take the position that bees have to secrete wax, and that if comb or foundation is used the wax is lost. But, is it true that bees have to secrete wax? I greatly doubt it. Nature has not arranged things that way. The cow secretes milk when there is a young calf that must have milk. When the bees need wax to form comb, then we find wax scales in the wax-pockets, otherwise we do not find them. I feel quite certain of this. I have hived swarms on combs, on foundation, and on frames with neither comb nor foundation. In the first two cases the bees would be very active, and it would be very difficult to find any wax scales. In the other case, most of the bees were very quiet, and almost every one would have wax scales in the wax-pockets. Even those flying out would show the scales. Now, if, as some contend, the bees in the first cases had to, and did, secrete the wax, where were the scales? I could find no signs of them, and do not believe they had any existence. In case of using foundation in brood-chamber and in supers, I have often had great difficulty in finding a bee with the wax scales to show my class; but, once hive a swarm in an entirely empty hive, and how soon we could find the scales! Indeed, it was hard to find a bee without them. It is hard to explain just how the bees regulate this matter. I have thought it was through activity. If very active, no scales are secreted; if quiet, or active to only a limited extent, then wax secretion was active. When we work mares hard, the young foals get too little milk. The mares can not secrete a full supply of milk, and work hard at the same time. Is it not quite possible that the same is true of bees? When they need comb, they hang quiet in graceful festoons from the top of the hive, and wax secretion goes on rapidly; and the material for the beautiful combs is abundant. When no comb is needed, true to their instinct they hie forth to gather sweet, and wax secretion is nearly or quite suspended. This hypothesis is not without support from analogy. The wax is much like our fat or adipose tissue. We know that it is the sedentary men that become rotund, while our Cassiuses—the lean and hungry men—are generally active. This fact does not necessarily prove that it is wise and profitable to buy and use foundation. Whether foundation is profitable or not, must be determined by actual trial; but that we should desist from its use to save wax scales that else will be secreted and lost, I think is not proved. I think a little close observation will convince any one that bees secrete wax only when, in the economy of the hive, they need it. A. J. COOK.

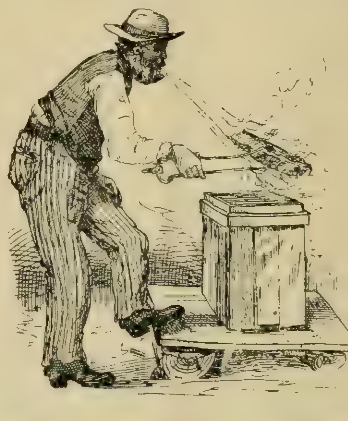
Agricultural College, Mich.

[Friend C., I am very glad you have brought up just this point. I once thought just as you state it; but other things have tended to change my opinion somewhat. For instance, where we feed a colony of bees tremendously with sugar syrup, if feeding is kept up for a sufficient number of days wax scales will form in great numbers; and if they are not permitted to build comb, these beautiful pearly scales of wax will fall on the bottom-board in great quantities. You know I once fed a single colony all the syrup that a barrel of sugar would make; as I wanted them to fill and seal over some combs to give to other colonies, they were not permitted to build comb at all, except capping cells. Well, the great difficulty in the way of the success of this experiment was, that so much syrup was consumed in the secretion of wax—wax that fell to the bottom-board—a good deal of it in the form of wax scales. In hiving new swarms on a full set of finished combs (or two full sets, if you choose) we did not find very many scales on the bottom; but the bees filled up all the corners, and built bits of wax all through the corners and crannies of the hives, and put considerable quantities of wax on the top of the frames. As this matter is one of great importance, I hope that we may have more suggestions on the subject. Although we have foundation to *sell*, my opinion is, and has been for a long time, that, where the brood-combs and honey-boxes are all filled with foundation, more or less wax is lost. I hope you are right, but I fear you are not wholly so in your conclusions.] A. I. R.

RAMBLE NO. 39.

IN MASSACHUSETTS AND CONNECTICUT.

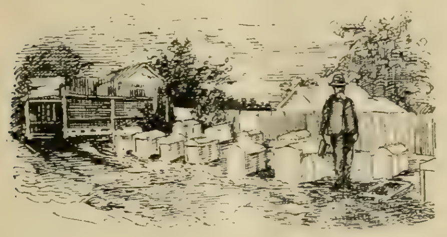
After a few changes on the many lines of railroad in this portion of Massachusetts I arrived in Georgetown just as the shades of evening were falling. Here I met an ex-pastor of our little Congregational church at home, and who had given us the words of life for several years. This brother was anxious to hear all about our home prosperity. The doubling of our church-membership through a long-hoped-for and prayed-for revival, and the building of a beautiful new church, were all precious things for him to hear. Our talk was necessarily brief upon bee-matters, as the only acquaintance our friend had with bees was through a brother-minister who had lately taken up bee-keeping as a recreation; and my clerical friend was quite elated over the fact that this brother, after studying up on bee-matters, went out among the farmer bee-keepers and told them more about bees than they ever knew before.



THE SCOTCHMAN AND HIS SMOKER.

"Why," said he, "it is astonishing how ignorant some people are of the common every-day companions of their lives. To illustrate," said he, "a Scotchman in a remote county had never heard of a smoker, and to subdue bees he carried a billet of wool from the stove with the tongs, and wafted it over the hive; and he believed that each drone laid an egg, and then sat on it till it hatched!" The idea was somewhat peculiar, but as I had come across such an idea before in my travels, I was not over and above surprised at it. It was a pleasure for me to talk with this clerical friend, for his moments of converse were packed with valuable information.

But, again the feet of the Rambler sought pastures new; and as the shades of another night enveloped the earth he was over 100 miles away, and in the land of steady habits and —wooden nutmegs! The town of Southington, Ct., charmed me for two days. Several years ago I visited this town and found it a growing manufacturing village. This time it had been incorporated into a borough, and the reason for its growth I could readily comprehend, as I frequently stumbled through a shoal of baby-carriages. I have no doubt this will soon be a large city.



JOSHUA BILLS AND HIS APIARY.

In this lively borough I found a live bee-man, Mr. Joshua Bills. To make all of his spare time useful, Mr. Bills is proprietor of a store for books and stationery; conducts the telephone office, and is also collector of the water-tax. He is connected with several other items too numerous to mention. Mr. B. has a pretty apiary of 21 colonies in Root and Falconer chaff hives. The average honey-yield in this locality is about 50 lbs. per colony; and at the time of my call, the bees were at work upon a flower of the aster family. The home market consumed all of his surplus. The aforesaid babies were rapid consumers of sweets, another evidence that Southington is to be a large city. Mr. B. has but little competition. His most extensive rival, Mr. Holt, lives out several miles in the country, and is a veritable Huber, as he is a blind man; but for all that he is quite successful, being aided, where eyes are needed, by Miss Holt.

The prosperity of Southington is derived from iron-rolling mills, bolt and nut shops, manufactories of novelties, cutlery, including the Yankee boys' jack-knife, Britannia ware of many beautiful designs, and common screws. While in Providence, Mr. Miller and the Rambler were denied admittance into the extensive works there located; but here, after passing the ordeal of a few questions, George (that's my brother-in-law) and I were allowed to pass, and entered a very noisy room where over a hundred machines were working (or, rather, biting) wire from large coils, and turning it out into screws of various sizes. The work is all done by automatic machinery. The little flat-headed pieces are picked up by steel fingers, chucked, and the screw-thread cut. They are then dropped into a box complete, and in an incredibly short time. All the workmen have to do is to change boxes or fill the hoppers when the automatic fingers seize the pieces. And now when I drive a screw home with the screw-driver, I think of the wonderful machine that made it, and am thankful for the genius that has given us so many useful things which are made so rapid and at such small cost. Wonderful are the days in which we live!

RAMBLER.

THE MILLIONAIRES OF AMERICA.

ARE OUR RICH MEN, AS A RULE, WICKED MEN?

Brother Root:—I have just read Alvin L. Potter's letter in Feb. 1st GLEANINGS; and I must confess that, when I read what you had to say in the December issue, I felt somewhat as Mr. Potter has expressed himself; but "charity suffereth long, and is kind;" and I believe you want to do what is right; but it appears to me you are not posted in that line; and Dr. A. B. Mason, I think, is a little off too. I should like to quote you a few passages of Scripture: Psalm 37:16: "A little that a righteous man hath is better than the riches of many wicked." Are not the rich nearly always wicked men? Prov. 30:8: "Give me neither poverty nor riches." The Wise Man thinks it not best to be rich. Dr. Mason does. Solomon says, "Labor not to be rich."—Prov. 23:4. "Deceitfulness of riches choke the word."—Mark 4:19. "How hardly shall they that have riches enter the kingdom of God."—Mark 10:23. Then why wish for more millionaires? "Woe unto you that are rich."—Luke 6:24. "Woe unto you lawyers also, for ye lade men with burdens grievous to be borne, and ye touch not the burden with one of your fingers"—Luke 11:48. Are not our legislative halls full of lawyers? and are not many of them worth their millions? I claim that no man has ever *earned* an honest million. If that is so, how is it possible for this country to prosper, and the people be happy and out of poverty, when we have so many rich men? Why, John D. Rockefeller is worth 135 millions; W. W. Astor, 120; Cornelius Vanderbilt, 90; Jay Gould, 75; Henry M. Flagler, 60; Charles Pratt, 55; Wm. K. Vanderbilt, 50; John H. Flagler, 40; Fred W. Vanderbilt, George Vanderbilt, William Astor, and Louis C. Tiffany, are worth 35 millions each; and I have the list of hundreds more, running down to three millions each. G. F. HESELTON.

Homeland, Mo., Feb. 3.

[Dear brother, the figures you give us, if they are indeed true, seem to indicate, I admit, that there is something wrong. But let us remember that, besides the good texts you quote from the Scriptures, there is another one that says, "Why beholdest thou the mote that is in thy brother's eye, and considerest not the beam that is in thine own eye?" Please bear with me if I suggest that there is danger—yes, very great danger—of a bad spirit getting into *our* hearts also, when we undertake to discuss these matters. When we get to feeling bitter and envious toward the millionaires, we are certainly in the wrong, whether they are or not. Now, it seems to me your mistake is in your *sweeping* assertions. You claim that no man has ever *earned* an honest million. Please bear in mind, dear brother, that George Muller, one of the grandest missionaries the world has ever known, and a home missionary at that, handles money by the millions of dollars. In fact, the Bank of England has said, if I am not mistaken, that they would honor a draft with his name to it, for a million of dollars. Surely you do not mean to say that *he* is a wicked man. This vast sum of money that he controls has been given into his hands in answer to prayer, and his life and work have been before the world almost like a modern miracle. I admit that this is not quite a parallel case, for in one sense Muller is a poor man. He uses this property for the benefit of the orphans and destitute of the great city of London. Now, is it not possible that some of these men of property you mention are using their property in a like way? Ernest just informs me that our schools of learning—our colleges and seminaries—were, many of them, founded, and now kept going, by our millionaires. In regard to your Bible texts, if you will consult your pastor or our doctors of theology, and the commentaries, they will tell you that the word "rich" in a scriptural sense refers to those who lead a life of selfishness and ease; so in reality the word describes the *way* a man lives, rather than his standing at the banks. We all respect and honor a man whose word and signature are as good as gold; but we as a people do not respect nor honor him who looks with disdain upon the workingmen of our land, especially those who work with muscle as well as brain. Let us work and pray that our rich men may become Christians, and the spirit of Jesus Christ will manage the money matters.

You err, friend H., in assuming that money must be *earned* in order to be honestly owned. Some years ago a babe was born in Hoboken, N. J., and he was worth $40,000,000 before he could use a cent. That money founded the Stevens Institute of Technology in Hoboken—one of the grandest institutions in this or any other land. Grand old Peter Cooper was worth millions over and over; and yet every workingman in New York loved him as he did his father. When he drove along Broadway, by general consent the teamsters made way to let the old philanthropist pass by in his plain old shay. Why? Because he gave to the people of the world the celebrated Cooper Institute in New York, where free instruction is given in all the arts and sciences. George Peabody gave $17,500,000 to the poor of London, to improve their homes. Vanderbilt gave half a million to the Fisk University, of Nashville, Tenn. Space would fail us if we were to tell all the good things that rich men have done for mankind. Certainly, God designs money to move in large masses, just as he collects the water in lakes and seas. What would the world be if the water were all equally divided?

You ask, "Are not our legislative halls full of lawyers? Perhaps you do not mean to reflect on the lawyers of the present day. The class in the text you quote certainly does not mean lawyers as we know them at the present time. Please remember that our fathers, sons, husbands, brothers, are lawyers; and to condemn them in toto would be as unjust and unkind as to say that the grocers of our land are all rascals. Since I have been on the school-board of our town I have become acquainted with more or less of our lawyers, because we always find it wise to have at least one lawyer on the board; and I have learned to respect them and to look up to them as I have never done before. As a rule, they urge people not to go into law; and several times I have seen them give their time gratis to point out to farmers, and other classes of people uneducated in law, the folly and injustice of the thing they had in mind. We know there are many of them who are not Christians, and we lament it; yet I have known even these to give advice that was very much in line with what we might expect from the pastors of our churches. If we have the right kind of love toward our neighbors we certainly shall not be in *haste* to decide they are rascals, even if they do happen to be lawyers.

Now, dear friends, had we not best let this matter drop right here? I admit that I am not posted, and that I am unable to handle politics and finance; but I do feel that it is in my province to say that these troubles, like all others that threaten our land of liberty, are to be remedied in the line of the text, "Not by might nor by power, but by my Spirit, saith the Lord of hosts."]

THE REASON WHY.

A PLEA FOR THE CROSSWISE L. FRAME; A GOOD-NATURED SCORING OF SUPPLY-DEALERS; WANT CLOSED-END FRAMES.

Mr. Editor:—While the hive and frame question is one main topic at present in GLEANINGS, and everybody is talking, will you allow me to say my piece, as I see you sometimes allow contrary people to talk? Why is it, that, when you were getting up a new hive (the Dovetailed), you didn't embrace one more change, and thus make it a perfect hive—that is, a change in the frame, and make it to run crosswise of the ten-frame hive, instead of lengthwise? After testing almost all of the sizes and styles of frames in use, and for many years, I am fully persuaded that the regular ten-frame Langstroth hive, with the frames crosswise, has more good features than any other hive I know of. I know, too, that many will "kick" at this idea. Why? Because they are not the standard frame. But, hold! Why is the Langstroth the standard frame? Because it started first; and after the patent expired, supply-dealers and hive-makers went to making and selling them, and each dealer began advertising and puffing their superiority over other makes. Editors of bee-journals puffed them. Why? Because they were supply-dealers, and it was to their interest to do so. Bee-keepers fell into line, and began buying and using them. Why? Because the bee-journals say they are the best. Soon the bee-keepers who had never used any other frame began writing for the journals on the superiority of the Langstroth frame over all others; then, when a standard frame is talked of, it must be the Langstroth. Why? Because there is most of that kind in use, and all the fixtures, such as supers, foundation, sections, etc., are for that sized hive. Why, bless you, nothing would have to be changed but the frame, in length, that's all; and the many conveniences gained would repay for doing that. Some of the points gained would be, no sagging, no wiring needed, combs not so liable to break in handling or extracting; straight combs; easier to contract by a division-board for weak colonies in spring. With a division-board in the center, it is in the best shape possible for two nuclei in a hive. Combs will not break in hauling to and from out-apiaries; are much nicer and easier for lady bee-keepers to handle; much better for starting nuclei with few bees. While the capacity for bees, brood, sections, and comb surface will be exactly the same as in the ten-frame Langstroth. I use wide frames for sections, and a frame this size holds just six 4¼x4¼ sections; or, by putting two brood-frames together, I have a wide frame, and it is much easier to get sections out than if it were one solid wide frame; then, when it is empty, I can use them for combs. But now I am making my frames closed-end, and they will not do for sections.

Mr. Editor, I was a little amused when reading your foot-note in answer to friend E. J. Baird's question on this subject, page 453, 1890:

"I do not know of anybody now who uses them to any extent. The only objection is, they are out of the beaten track." Why are they out of the beaten track, and not in general use, or not the standard? Simply because supply-dealers and bee-journals don't puff them, that's all. I can count at least ten bee-keepers who do use them, and like them too, and scores who would use them exclusively if they were advertised for sale. I have at present 50 colonies on Langstroth combs, and 125 on the crosswise frame. I know, by years of practice with both sizes of frames, which is best for all purposes, and I wish you had introduced your new hive with the crosswise closed-end or Hoffman frame, and break away from the beaten track for something better.

This is an age of improvements, you know. Ernest speaks favorably of Mr. Manum's frames not sagging. Not half of the large honey-producers here in the basswood region of Wisconsin use the long Langstroth frame; and Wisconsin, you know, comes to the front in honey production.

I could say much more in favor of adopting the crosswise Langstroth frame, and also show indisputable reasons why the long frame is not as good. I have no ax to grind. I am only a practical bee-keeper, and not a supply-dealer or hive-maker, except for my own use. But, let us still be progressive in hives as well as in all else pertaining to bee culture.

Orion, Wis., Feb. 23. W. T. STEWART.

[I wish there were more contrary people who would speak out their mind as good naturedly as you do. You have given us some excellent reasons why the L. frame is the standard; but you have not named them all. No doubt, for your locality and other places of a similar nature, the crosswise L. frame is better; but don't forget that localities differ. I know, that is, I think, there are places where the Quinby frame gives better results. I am also of the opinion that the fixed frames are adapted for most localities, but there are some places where they would not answer as well as the loose frame. There is a good deal of twaddle about localities making a difference in results; but when we come to talk about the size of frames, there is some sense about it.

Father Langstroth, years ago, experimented with a great many different sizes, and finally settled upon one in use by bee-keepers generally. The trouble with the crosswise frame is, that it does not hold comb enough to suit most bee-keepers. We want a comb not too deep, but one that gives plenty of brood-rearing surface, and that we get in the L. size.

With your crosswise frame you are obliged to handle 13 instead of 10, as in an ordinary ten-frame Langstroth body. There is quite a little difference you see.

One great reason why the L. frame is so generally accepted is because it is a compromise between the very shallow and very deep frames, and because, for most localities and most bee-keepers, it gives good results.

You overlook one very important fact. If the time has not already come it has almost, when over half of the hives in use will be eight-frame instead of ten-frame; so that the eight-frame people could not use the crosswise, even if they chose to do so; that is, the crosswise, if used at all, would have to be shortened —then what? there would be another frame.

Still another thing: We have had scores of testimonials to the effect that bees would gather about as much honey, and do about as well on the L. size as on any other, and that with comparative tests. But there are exceptions to all rules. In this case, take, for instance, that of the Dadants. Instead of using a *smaller* frame than the Langstroth, they want a larger one—the Quinby. And they say they have made comparative tests to prove the superiority of the larger frame. Now you call for a *smaller* one. Don't you think that the L. frame is a very nice compromise between the extremes, for most people?

You say no wiring is needed for crosswise frames. There are very few who will agree with you on this point; that is, those who have tried wiring and not wiring. A crosswise frame needs wiring, else why do so many use wire for square frames? It is true, that a *shorter* top-bar would be less liable to sag, but we compensate for that in the longer L. by making them ⅝ thick now.

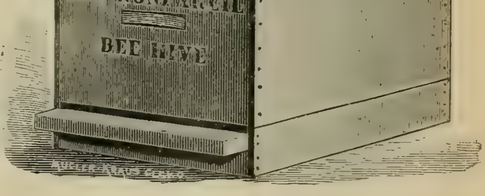
Perhaps two-thirds of those using other than the L. frames would be glad to use a standard size if they could make the change without expense. Why? Because, from the few comparative tests they have made they get just as good results from one frame as another.

I do not overlook the fact that you represent your own locality. You want a smaller frame. The Dadants represent their locality, and they want a larger frame. The fact can not be denied, that bee-keepers ought to have a standard, and that that standard ought to be the one that *most* bee-keepers will agree upon, and that is the Langstroth frame. The standard in England is the crosswise L., or very nearly that; but that is not this country. I think I can join hands with you in regard to the closed-ends; but when you advise changing the size of the standard, you will encounter a bigger job than you think for.] E. R. R.

THE NONPAREIL BEE-HIVE.

DR. TINKER EXPLAINS HIS HIVE.

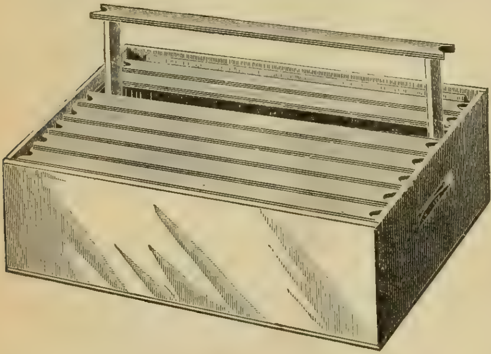
The engraving for the accompanying illustration was made four years ago, since which time the cover of the hive has been improved by making a square framework, similar to that of the Simplicity hive, and covered with sheet roofing steel, made here in New Philadelphia. An improved clasp of malleable iron, similar to the Van Deusen clamp, has been made to secure the removable side of the section super. Otherwise, the hive as now made is the same as the original. Where the hive is to be set into a winter case in the fall for winter, a very cheap cover and bottom for temporary use has been devised for all increase during the working season. In this locality, and further south, the hive in two stories will winter as safely as in



box-hives, but at a loss in stores sufficient to pay for a winter case in a few years. When the hive is placed in the latter, the safety of wintering, with proper care and good packing, is insured in our longest and coldest winters. The results of wintering in these hives have also shown that there is far less danger of dysentery when the two-story hive and winter case is used than in any other style of hive now made. At least, several tests in the same apiaries upon the same stores have shown complete immunity from disease when the bees in other hives like the American, the Simplicity, chaff, and several other kinds of hives, some of which were at least three times as large as the Nonpareil winter case, either all died or were so greatly reduced in numbers by dysentery that the colonies built up too late to get a crop of honey. In all of these instances the great difference in results seemed wholly due to the greater depth of the two-story hive, or to the free passageway between the stories.

THE NONPAREIL BROOD-CHAMBER.

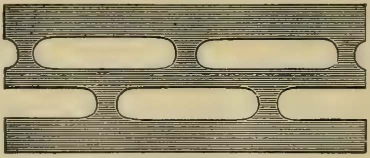
The chief feature of this hive is the size and shape of the brood-chamber. It will be noticed that it is a very plain and cheaply made storifying Langstroth brood-chamber, with a quarter-inch bee-space at the top above the brood-frames, and an eighth-inch space at the bottom below the frames. It contains eight Langstroth brood-frames, notched at the ends of the top-bars, similar to the metal-cornered Simplicity frames, the size being 17 inches long by 7 inches deep, outside measure. The top-bar is 18⅜ inches long, ⅜ thick, and one inch wide. The end-bars are 6⅜ inches long by ⅜ thick, by one inch wide; and the bottom-bar is 17 inches long, ¾ inch wide, and ¼ thick. To each of these frames we now attach a spacer, made on the principle of the Van Deusen frame-spacers. They fix the frames without destroying the movable function of the Langstroth brood-frames. The brood-chamber is 19⅛ inches long, 12½ inches wide, and 7⅜ inches deep. The inside measure is 17⅜ inches long by 11¼ wide.



THE NONPAREIL BROOD-CHAMBER.

Owing to the small capacity of this brood-chamber, which contains 830 square inches of brood comb (and after making allowance for bee passageways at the ends and bottom of the combs, not ordinarily over 800 square inches), it is impracticable in the production of comb honey without a queen-excluder. The latter is the wood-zinc combination, the strips of zinc being ¾ in. wide, and two-rowed, as in the cut.

The perforations are about ¾ inch long, so that the excluder contains about 300 of these perforations, which seem to be essential to the ready ripening of the stores in supers. The framework of the excluder is made of half-inch stuff, rabbeted to receive the slats, which are ⅞ inch wide by $\frac{3}{16}$ thick. The queen-excluder for this hive is made with continuous passageways; that is, the zinc is placed in the framework so as to come over the spaces between the combs. The break-joint queen-excluder is a disadvantage; and when the stories of the hive are piled up above 24 inches high it becomes a serious disadvantage. As the system of management with the continuous-passageway queen-excluder almost entirely obviates all burr-combs, it will be seen that the break-joint queen-excluder can have no merit on this hive.



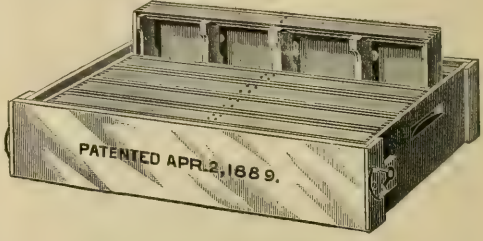
TINKER'S PERFORATED ZINC.

THE NONPAREIL SECTION SUPER.

This consists of a case with a removable side, containing 6 wide frames holding 4 sections in each. The frames are made with a center-bar to prevent sagging, of the same shape as the sides of the open-side sections. The five separators are made of wood, and perforated. They are $\frac{1}{16}$ thick, and 4⅝ inches wide, and are placed loosely in the case, so that any one of the frames of sections can be taken out, and the bees be readily shaken off, which can not be done where the separators are nailed fast to the wide frames. As the separators come down to the bottom of the sections they entirely prevent the attachment of the combs in the sections to them. They are not only cheaper than tin, but are, on account of the less liability to the attachment of the combs, greatly superior to tin. They are also, when sawed, more durable than tin, lasting an indefinite time. The cut of section super shows the improved malleable-iron clasp.

THE WINTER CASE.

This is made of very thin stuff, a little less than $\frac{5}{16}$ of an inch thick, making the case very light and easy to handle, weighing not far from 25 lbs. The sides of the case are 22 inches long, and are nailed to the framework at the top and bottom, so as to stand upright, making the case both waterproof and very durable. The bottom of the case is made of the same thin stuff, as also a part of the cover. The framework of the bottom is 3 inches wide by one inch thick, the two side pieces being rabbeted to receive the thin stuff for the bottom. Two braces are nailed into the framework at the bottom, to prevent sagging when a great weight of honey is in the hive. The entrance is ⅜ by 11 inches, and is in a line with the bottom, so that any refuse, in wintering, may be raked out. However, we have never found it necessary to do so, as the bees will do it cheaper than we can.



PATENTED APR. 2, 1889.

THE NONPAREIL SECTION SUPER.

A block 1½ inches thick, and wide enough to support a queen-trap, is nailed to the lower framework at the entrance, and a portico is attached above to keep off rain and snow. The top-frame is made of ¾-inch stuff, 1¼ inches wide. The cover is a frame made of ⅝-inch boards, 2½ inches wide, like a picture-frame, and rabbeted on the inner top at the sides to receive the thin stuff to support the roofing tin or sheet steel, whichever may be used. The size of the case is such that a sheet of 20 x 28 roofing tin will cover it and leave room to lap over the sides so it may be securely nailed. Thus this winter case combines a bottom and cover complete in itself, and is preferred with the bottom attached solid to prevent the effects of dampness from the ground and rain, which is sure to affect the bees more or less where the bottom is not made fast.

The management of this hive for comb honey will be the subject for another article.

New Philadelphia, O. Dr. G. L. Tinker.

FOUL BROOD.

HOW TO TELL WHETHER COMBS HAVE BEEN INFECTED.

[Read at the Michigan State Convention at Detroit.]

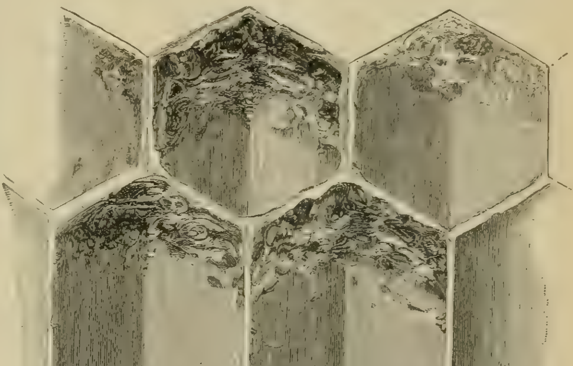
Though I discussed the subject of foul brood at our last annual meeting, I have, at the request of our secretary, prepared a sort of supplemental paper on the same subject; and, first, I shall add a further word to aid in the identification of the malady. Enough has been written about sunken and perforated capping, and the color and viscid character of the brood recently dead of the disease. In the case of weak colonies generally, and of all colonies during the breeding season, some of these indications will be found if the disease is present, and will furnish certain means of a correct diagnosis; but it is to be noted that, after the breeding season is well over, a strong colony, though badly diseased, exhibits none of these indications. The cappings, if ever present, are all nicely cleared away, and the dead brood is entirely dried up—mere scales, almost of the color of the comb itself, lying fast to the lower side of the cell, and drawn back more or less from the opening. I have samples of affected comb with me, one of which illustrates this point, though the sample is hardly a fair one, as the scales resulting from the dead brood are more apparent than they usually are, being less drawn back, and thicker, and rather darker than they are often found.

To detect the disease in strong colonies, some little time after brood-rearing has ceased, open the hive and apply your nostrils directly to the combs as they hang in the hive. If the disease is present to any extent, and your olfactory organs are sensitive, you will detect an odor more or less strong, which may be described by the term "old." But not many, at least at first, could say by this test with any degree of certainty whether the colony were diseased or not. It is to be taken only as an indication.

Now take out three or four combs, one by one, from near the center of the brood-nest, and hold each with the bottom-bar from you, in different directions, until the light strikes well into the *lower side* of the cells, when, if affected, the scales I have described are very evident. The sample makes this plainer than any amount of description can do.

In contending against the evil there is nothing so important as an active knowledge of the sources whence the danger of spreading the contamination arises. With this knowledge, I am convinced there is little necessity for fear that the disease will spread to healthy colonies, if only the sources are within reach of the apiarist. If many wild bees, among which it has a foothold, are in the vicinity, it must become eradicated there in the course of nature before the apiary is safe; for every wild colony affected will, in time, surely die, and its honey, if any be left, will be appropriated by other bees, and the plague unavoidably disseminated. This danger can not well be guarded against; but those at home may easily be reduced to a very small figure. They fall under three heads—those from infected honey, from infected combs, and from infected hives.

Under the head of hives is included, of course, all paraphernalia. I think the principal danger from this source arises from infected honey which may have been left on the parts of the hive by daubing or otherwise. No bee should be allowed to visit them; and, as soon as it may be safely done, they should be boiled in water, scorched with flame, or burned up. Either method is effective. Infected combs are dangerous, not only from the honey, but also from the dead brood which they contain. Every dead larva is a bundle of seeds; and when moistened by honey, new brood, or otherwise, they are released, and carry death wherever they go. Such combs are safely rendered innocuous by fire or boiling only. The extremest caution in changing combs from one colony to another should always be observed. There is no more certain and rapid way of propagating the malady. Infected honey itself, however, is the chief medium by which foul brood is disseminated, and so it is the principal source of



FOUL BROOD SCALES IN COMB. MAGNIFIED FIVE TIMES.

danger. The bees are sure to contract the disease thereby, whether they obtain it by deliberate feeding on the part of the apiarist, or by gathering up what is carelessly allowed to drip and to be left exposed about the apiary or by robbing. When once pointed out, every bee-keeper should be able to guard against the danger arising from the feeding and the dripping of honey; but to secure protection against robbing, extraordinary care is often required. If bees were deprived of their disposition to rob, foul brood would soon be eradicated. This can not be done. Indeed, to one who has had to deal with the plague, this disposition seems to be increased thereby. The more powerful nations of Europe keep their eyes upon the Turk as the "sick man," waiting for occasion when they may profit by his dissolution. The bees emulate the example of the nations. As soon as they catch the odor of the disease issuing from a hive, they promptly label it "the sick man," and eagerly watch and wait; and at length, unlike Russia, Austria, and the rest, instead of holding each in check, they all turn in at the nick of time to complete the work of destruction, and, like many a human individual and nation, find the seeds of death wrapped up in their ill-gotten wealth.

From infected colonies that are reasonably strong and in good heart, with sound hives having moderate entrances, I should not apprehend immediate danger, but I would keep a sharp lookout for the impending decline. It behooves him whose bees are infected, whether or not he obeys the general injunction, "Keep all colonies strong," to be instant in his efforts to keep all diseased colonies strong. No one will understand me to advise building up such colonies. I mean, only, that no weak one in a diseased condition should be tolerated for a day; and, indeed, it is to be hoped that this advice will be seldom applicable; for it is to the interest of every apiarist to banish the disease by the most effectual method, as speedily as possible.

I hardly need add, that the taking of bees from a diseased colony, and adding them to a healthy one, would as certainly convey the disease in the honey carried as though it were brought by robbers.

I shall close here, for I am sure that, if due and timely heed be paid to the directions given herein, and in my paper of a year ago, no one need be greatly alarmed nor very seriously damaged by foul brood; and I only hope that none of you may ever need even to call them into exercise.
R. L. Taylor.

Lapeer, Mich., Mar., 1891.

[I have carefully read your paper, friend T., and I consider it one of the best that has ever been given on the subject. Your method of diagnosing diseased colonies after brood is hatched out, and combs have, after a fashion, been cleaned up, is an exceedingly valuable one; and although I have read a good deal of foul-brood literature, I believe you are the first one to give it. The sample comb that you gave at the convention was forwarded to us, and I exhibited the same in person to our artist, showing him the scales and what we wanted illustrated. After examining it he answered that it was a hard thing to illustrate. Then I said, "Enlarge the drawing five times. This is such an important matter that we want everybody to see it." He did so, and I am glad to present the result above. The scaly appearance around the edges of the cells is perhaps a little exaggerated, but this was necessary in order to show them. That you may understand it better, I will say that the piece of comb was stood on end, and a knife sliced right through three or four of the cells, longitudinally. The other row of cells is shown just back. A few scales are seen at the bottom, but more of them are attached around the edges, and that side or sides of the cell which are the bottom when in the hive. I shall be glad to have friend Taylor tell us how near the engraving does justice to the thing itself.

Your methods or precautions for preventing the spread of the disease are excellent, all of which we have tried. We can not place too much emphasis on being careful.

Perhaps some may wish to know, in this connection, what Mr. Taylor's method of cure is. It is very similar to the one we give in the A B C book; in fact, I believe it is just the same, because we followed Mr. Taylor.]
E. R. R.

THAT TRADE-MARK.

MR. HEDDON ARGUES FOR ITS ESTABLISHMENT IN THE BEE-KEEPERS' UNION.

On page 143 I see you quote the words of an anonymous writer in the *American Bee Journal;* and in your foot-note on the next page you say that "some of the points are well taken;" but some way I fail to find much argument in the quotation. In the first place, "Bro. Heddon" has never been "enthusiastic" nor has he yet "waxed eloquent" over the trade-mark scheme, but has said from the beginning that it was only a snap idea gathered in a moment's time at the late Detroit State convention. You were there, I believe, Mr. Editor, and will recollect that, at the outset, it was admitted by all that consumers of honey had full faith in the purity of goods straight from the hands of producers. I think few will deny the prevalence of such an opinion. Well, as producers have, in the past, placed lots of poor honey upon the market, and surely as much adulterated as they ever will, that washes away that point presented by Anonymous. The Union will not warrant any thing, neither need it; for already has the public full confidence in the purity of all honey put up by producers. The object of the trade-mark is to let the whole public know at all times just how to quickly determine which is from the producer. Mr. A. can not see how a trade-mark can be obtained from the government, for the Union. Well, your gentle subscriber can see, as well as he can see some other things connected with patent laws and rulings, which many others can't get even a glimmer of. The manager can get a trade-mark of a 30-years' longevity for $40, and then make out an individual right to any one he pleases. This can be done at a cost not exceeding one cent per person. I wish our friend A. would tell us how the trade-mark scheme can hurt the Union "awfully;" that is what I can't see. Will A. be as kind to me as I have been to him, and enlighten me? If the Union doesn't handle the trade-mark scheme, who will? Only some organization of actual honey-producers can afford to give a great number of bee-keepers such an advantage, at cost. Already the manager of the Union has to be on the alert to detect any attempt on the part of any bee-keeper to creep slily into the Union for its protection after persecution has already begun. It will be just as easy—yes, much easier, to keep out of the Union, or keep the trade-mark out of the hands of a city packer of honey who happens to import a wasp-nest into his garret in order to be classed as a honey-producer. It will be much easier than to prevent or detect perjury when a witness has taken an oath which gives his statements a hundred-fold weight. I think we shall have little trouble in plugging up the small holes in this dipper, the same as we have to do in nearly all of the affairs of this world. If our basic principle is right, our details can be made to join in the success. Are they? So far I don't see that they are not. Do you? JAMES HEDDON.

Dowagiac, Mich., Feb. 21.

AIR-CHAMBERS VS. CHAFF PACKING.

S. A. SHUCK DECIDES IN FAVOR OF THE AIR-CHAMBER.

Considerable is being said about "dead-air chambers" in double-walled hives, as against chaff packing. The question arises, "What is known as to the difference between hives with double walls packed with chaff or other light material, and those with double walls and no packing?"

Without calling in question the views set forth by other writers on this matter, I wish to present a few thoughts which I believe have not been set forth heretofore. In the first place, I wish to contrast air-chambers with those packed with some light material. It is well known to all those who have acquainted themselves with the action of cold and heat when applied to air, that heated air rises up, and chilled or cold air settles down. A moment's thought in this direction will show that, as soon as the temperature outside of hives containing the so-called dead-air chambers becomes colder than that on the inside of the hives, the air in the chambers becomes active, and can not be said to be dead. As the outer walls of the hives become chilled, they in turn chill the atmosphere adjacent to them on the inside of the air-chambers. This chilled air settles to the bottom of the chambers, while that near the inner walls of the hives, being warmer, rises up to the top of the chambers, thus starting a circuitous motion, which is continued as long as there is a difference between the temperature outside of the hives and that within the hives. It will be seen that, if these chambers were filled with some light material, such as chaff, this circuitous action of the air in these chambers is prevented, the process of cooling is retarded, and the protection afforded the bees in any hive is in proportion to the retarding of this cooling process.

No little stress is being placed upon the superiority of air-chambers over chaff packing, by some writers, while it is conceded by many practical bee-keepers that bees can be packed too warmly, even during our most severe winters; while it is known, on the other hand, that large air-chambers are not beneficial. As proof of the foregoing, it is only necessary to mention that house-apiaries have proven to be the poorest of winter repositories for bees, when no further protection is afforded than that of the building and the hives. But where the hives are thoroughly and carefully packed in dry chaff, bees winter as well, perhaps, in house-apiaries as anywhere.

While it is easily shown that chaff packing affords greater protection to the bees, there are other facts to be taken into consideration. Hundreds of bee-keepers have learned that the effect of the direct rays of the sun on the hives is as beneficial to the inmates as it is to our cattle, hogs, sheep, horses, etc. Hence, it will be seen that, while the chaff packing is a protection by retarding the cooling process, it also becomes a hindrance in the process of warming up the hives and their inmates. If the hives were packed full of bees during all severe weather, the benefits derived from the direct rays of the sun would be greatly lessened, and those afforded by the chaff packing would be proportionately increased, owing to the protection given to the inner walls of the hives. But, on the contrary, the hives are usually less than half full of bees; and, not only this, the entrances being open they permit the unoccupied portion of the hives to become nearly as cold as the outside atmosphere. Owing to these conditions the difference between the protection afforded by chaff packing and air-chambers is so slight that it would be difficult to observe its effects upon the bees.

There is still another difficulty encountered in chaff packing—that of keeping the chaff perfectly dry. If the chaff becomes damp it is more detriment than good; and the injury resulting from moisture in this chaff packing is just in proportion to the degree of dampness and the severity of the weather; as, the wetter the packing and the colder the weather, the nearer it approaches the condition of an ice-chest; and the longer it is in thawing out, and the less the influence of the sun's rays upon the hives. This, I think, is the principal source of unsatisfactory results from chaff-packed hives; and owing to the difficulty in preventing moisture in chaff packing, it is highly probable that air-chambers will give us more general satisfaction; notwithstanding, the degree of protection afforded by these air-chambers depends largely upon their being absolutely tight, so as not to lose the heat except as it is driven through the inner walls of the hives by the action of the cold on the outer walls.

Liverpool, Ill., Feb. 9. S. A. SHUCK.

HERE AND THERE.

SHORT NAMES FOR THINGS, ETC.

CAP-KNIFE.

Why not drop the long and awkward name, "uncapping-knife," and adopt the name I use for it, the cap-knife? You are welcome to it, and why doesn't it fill the bill?

BINDING GLEANINGS.

And now let me give you *my* plan for binding GLEANINGS. Get some of those T-shaped brass paper-fasteners, which lawyers and others use to fasten legal cap and other papers together. Take eight numbers, four months GLEANINGS, leaving on them all covers and all advertisements. The latter are often as valuable as any other part. Arrange the eight numbers carefully, in nice even shape, and, with an awl, punch three holes in the proper places—one in the center and one near each end. Now drive a T through each, having the point come through into a gimlet-hole or other small hole in the bench, or in a board. Then turn the volume over and clip off the sharp points of the T with cutting-pliers or shears. Turn down and then hammer down the points of the T with a light hammer, and it is done. You now have a nice handy little volume about the size of a copy of the *Century*, and a year's GLEANINGS makes three of these little volumes, which are much nicer and handier than a year in one volume. Bound thus, eleven numbers of the 1890 *Review* will make a nice little volume; and the numbers for 1891, and the Dec., 1890, number, will make two nice volumes.

CAPTIONS AND NAMES.

And now, friend R., permit me to hint to you that G. M. Doolittle, Borodino, N. Y., wouldn't look a bit worse if placed just under the caption than it does at the tail end of an article. That is, I—I mean to say that it would look just as well under the caption. And if you would only place it there, you would confer a special favor upon every busy reader of GLEANINGS who can afford to waste no precious moments of his limited reading-time; and you would receive the heartiest thanks of thousands of such busy readers. Also, please give plenty of catch-lines. They are always helpful. And whatever you have to leave out, please don't leave out any foot-notes. Do you fully realize that, with the exception of a few of the ablest articles, they are the most valuable and helpful part of GLEANINGS? And that is quite right, for so they ought to be. By the aid of caption and name, catch-lines and foot-notes, the experienced and busy apiarist will often be able to catch, in a minute the gist of the article, or be able to decide whether it will pay to read the whole of it, or how much of it he can afford to read.

THE QUESTION-BOX.

This is a very valuable addition, and even GLEANINGS seems a little more spicy when taken with a *Straw* in it. J. W. MURRAY.

Excelsior, Minn., Feb. 17.

[The "cap-knife" is shorter and just as good. Accepted usage, however (and this is something we can't very well change if we would), compels the use of the longer name, "uncapping-knife."]

EVAPORATING HONEY.

SUN HEAT, A LA BOARDMAN, WON'T DO. SO SAYS A CALIFORNIAN.

On page 50 Mr. Boardman asks whether the sun evaporator is not the secret of some of the California honey not candying. I think if he would travel around among California apiaries, as Mr. Root did, he would come to the conclusion that it is not the secret, because he would find very few if any sun evaporators. I admit that honey exposed in a sun evaporator for several days will not candy, at least for a long time; but our sage honey will often remain liquid several years without candying. On the other hand, some of our spring honey will sometimes candy in a week or two after extracting.

The carload of honey which I sold to Mr. Root ran directly from the extractor into large tanks, from which it was drawn into new five-gallon cans; and I do not think you will find any of it candied yet. My experience with sun evaporators has not been very satisfactory. They make the honey darker, and change the flavor, and do not evaporate fast enough. I should like to ask Mr. Boardman whether he can take this honey, extracted before any of it is capped over, and evaporate it thick, without changing the color or flavor; and if he can, how many of his evaporators would it take to reduce 2500 lbs. in one day? We all know it would be a great saving of time and labor to ourselves and the bees if we could extract all of our honey before it is capped; but the point is, whether we can evaporate it artificially, without injuring the color or flavor, as economically as the bees can. I say, no, not by the sun's heat. It is too unreliable, even in California. When your honey is thinnest, the weather is often cloudy or foggy. My only hope now is in "vacuum-pans." I think honey should not be heated to over 150°Fah., and it will not evaporate very fast at that temperature unless in a vacuum. I wish some one living near a condensed-milk or sugar factory would get them to condense some of their honey, and see whether it affects the color or flavor; and if not, find what it will cost to reduce a ton of honey to 1500 lbs. Perhaps it will pay to have small vacuum-pans, and work the air-pumps by hand or horse power. This is extracting the water from honey by power instead of heat. J. F. MCINTYRE.

Fillmore, Cal., Feb. 16.

[Friend M., I want to thank you for having given me my first clear idea of what is meant by "vacuum-pans." We second your request. Perhaps somebody who has used the arrangement will tell us more about it.]

DISCOURAGEMENTS OF BEE-KEEPING.

AN OLD VETERAN RECOUNTS THEM.

[Read at the State Bee-Keepers' Association, Madison, Wis.]

As the bright side of bee-keeping is the one generally presented to the public, some items from the other, or discouraging side, ought to be in order. When I commenced keeping bees 34 years ago, we had no bee-literature of any account to aid us, but we had plenty of good pasturage, any amount of basswood timber, wild flowers, buckwheat, and but few bee-keepers, and nearly every season seemed to be a good one for honey. Honey bore a good price, foul brood was unknown, and even the moth-miller had not found us out. The prejudice against bee-keepers by farmers, fruit-growers, and others, of late years existing, was then never mentioned; but those good old times are past, and the favorable conditions then existing can not again be enjoyed. This thought discourages one. The improvements and the advance made in bee-keeping since I began have been marvelous. The movable frame, the extractor, comb-foundation mills, sections, cases, smokers, veils, different races of bees, large factories for the manufacture of supplies, and the excellent literature pertaining to bee-keeping, now available, have boomed bee-keeping. All items relating to big honey-yields and rapid increase have been given, copied in agricultural and other papers. These have advertised the business till the result has been that we harvested a countless throng of bee-keepers. As the saying is, the woods are full of them, and, we might also add, the open ground too.

Of the thousands who have commenced bee-keeping in the last few years, I am satisfied that, had they known fully the chances and the actual conditions as they existed, half would have turned their attention to something else; but, being captivated by the big reports of some of the few most favorably situated, to achieve success they embarked in the venture, not considering the much larger number who had made a failure of the business.

This big crop of bee-keepers is discouraging to me. It may speak well for the advancement of the pursuit and the cheapening of honey for the masses; but every accession to our ranks is one more rival in the field to lower prices and share with us the pasturage. A large part of the beginners are inclined to cut prices, which are already low enough.

Another discouraging feature: While bee-keepers are increasing, pasturage is not. Basswood is fast disappearing; buckwheat is not raised nearly as much as formerly; wild flowers are disappearing before the plow, sheep, and cattle. One honey source, white clover, is on the increase, but is an uncertain honey-plant in our climate.

Fifteen years ago I had, including the home yard, bees in six places, the furthest yard being ten miles from home, with scarcely a rival yard that would lessen my crop; but for several years past, bee-keepers have increased to such an extent that last season I occupied only the home yard, and that was badly trenched upon by surrounding yards. The rest of my bees, 200 colonies, outside of those kept at home, I moved 28 miles, attempting to get them where there was a reasonable chance to make them pay expenses.

Another cause for discouragement is the appearance of foul brood at several places in our State.

The price of honey is also discouraging. This year, of all others, it would seem that honey ought to sell on sight; but many have found it hard to dispose of the little crop that they did have at any thing of a fair price. Honey is not like the staple farm products that have a fixed market price, and that will sell any day when taken to market. You have to look for your honey customer, and then he is not always easily found. I have looked for him sometimes at home, and sometimes abroad; and I have looked as far, even, as New York, and then not found him.

Still another discouraging feature is, that my bees went into winter quarters light in both bees and stores. I am not sanguine of being able to make a very good report for 1891, even should the season be fairly favorable.

The Bee-keepers' Union has been a comfort to me in the past; in fact, it sprang into life through my need, and came to my defense for its first work, and is still doing for the fraternity and individuals valuable service. Long may its officers live, and long may its banners wave; but I am discouraged because it does not number thousands where it numbers hundreds. In justice to ourselves as bee-keepers, it stands us in hand to be as prompt to chronicle losses and discouragements as we are items of success. I know it is more pleasant to tell of success than failure. We all like to tell a big story if a true one. But our interests demand both sides; so, let us see to it that we report both sides faithfully. S. I. Freeborn.

Ithaca, Wis.

[Friend F., we are glad to hear from you; and we are glad, also, to have you give us plain hard facts, gleaned from years of experience; but even if it be all true, exactly as you state it, bee culture does not differ very much from most other rural industries. They all have their ups and downs, and in one sense the field is pretty well crowded. A great army of people are looking in vain for something to do that is sure pay and has no discouragements, as you tell of. They do not find it. While in your State, and through the basswood region in your vicinity, some of your neighbors were so enthusiastic as to say that they never had a failure in basswood; but the failure has come already. Now, I do not believe, dear brother, that it will pay for many of us, at least, to become discouraged and give up. One of our bee-men was in to see us yesterday. He became discouraged because bee-keeping did not pay, and so he went into evaporating fruit. By the time he had a good crop, and a great lot on hand, the prices went down so he could not sell. Last winter he sold his evaporated apples for 5 c. per lb. because he was discouraged. This winter he said he could have sold them readily for 15 cts., which would have made a good profit, and paid a good interest during the time he held them. But he is now out of the fruit business. Let us do the best we can, year by year, leaving no stone unturned, as Doolittle says, to secure a crop; and I think we shall, as a general thing, fare as well as the rest of mankind. It is true, it is not well to have too many bee-keepers so crowded together as to overstock the locality. But I think this state of affairs will not continue long. The fittest will survive, and the others will give it up.]

THE NEW DOVETAILED HIVES.

TOO MUCH OR TOO LITTLE FOUNDATION; A SUGGESTION FOR EMMA WILSON.

Friend Root:—I have to-day finished nailing up 250 dovetailed bodies, 100 dovetailed supers; covers, 100 each, and bottom-boards, and 2000 Hoffman frames, all of the latter nicely wired. I have had only a boy 13 years old to help me, and have gone out selling honey and vegetables on an average of at least once a week; so you see I have been quite busy. All the above is for my individual use the coming season, and I hope to fill them with full swarms by natural swarming. I should like to say right here, that, although I have dealt with you extensively every year for over ten years, this last lot of goods has been the best, and has given me more satisfaction than any I ever bought of you before. You certainly are improving all the time in workmanship.

Now for a little chat in regard to several topics. I should like to ask those who advocate the use of less foundation, if they were offered all they could use free of cost would they not use full sheets of it in the brood-chamber, and full-sized starters in the sections? I am sure I would, for one, *every time.*

Your remarks on page 34, in regard to taking a partner, fit my case exactly. Three times in life I have been broken up by doing so, and I propose hereafter to have only wife and children as partners.

Tell Miss Emma Wilson to try an apron made of the waterproof cloth, recommended for hot-beds—the lighter quality; I think she will like it. It will be a little stiff at first, but soon gets limber and pliable, especially after being washed.

I have used bricks for recording the different operations in the apiary for years past, and prefer them to a memorandum-book.

KEENEY WIRING VERY SATISFACTORY.

As stated elsewhere, I have just finished wiring 2000 Hoffman frames, and I am surprised that any one finds fault with the bent nails. I think I have used, or tried, every method of wiring mentioned in the bee-journals since wiring frames has been invented, and none of them equals the Keeney plan, in my estimation. Perhaps friend Bunch (see page 100) nailed his frames together *first*, before putting in the wire nails and bending them; if he did, let him take 1¼-inch No. 18 wire nails; drive them through at the proper place, and then with small-sized pliers give them a twist. He will soon get the hang of it, and he will never nail the frames together again before putting the wire nails in. I can make them very uniform and yet twist them faster than a smart man or boy can drive the nails through.

HONEY FOR CHILDREN; HOW TO GIVE IT TO THEM ON SQUARES OF PAPER.

I have two little tots, aged 5 and 3 years respectively. They take a great interest in my work, and "want to help pa" every way in their power. I feel sure it would do you good, friend R., if you could see them come into the workshop every morning about nine o'clock, each with a little square of paper, and say, "Honey, papa;" and then I go to the barrel of candied honey and dig out a suitable quantity. It makes me smile to hear their "thanky, papa," and see them sit down by the stove and enjoy it. In the afternoon they repeat the same, as regularly as clockwork, from day to day. Some may think they might eat too much of it, and so get tired of it; but care is taken not to give too much at any one time. I find that, when given honey in that way regularly, they care little or nothing for the ordinary candies we buy; and as for health, if you can find healthier, rosier, or more active children anywhere, I should like to see them; and, by the way, friend R., I have a theory that, if they grow up accustomed to the daily use of such pure sweets as honey, they will never require a taste or fondness for stimulants or intoxicating liquors. Have you ever observed that any one given over to the use of intoxicants seldom or never uses sweets in any form? When a young man I met at social gatherings many friends and acquaintances; and when refreshments were served I noticed on quite a number of occasions that three of the young men present never touched any thing sweet, but were very fond of pickles and stimulating dishes. In a few years every one of them died of *delirium tremens*, from excessive use of intoxicants taken in secret. Since then I have found it the rule that, in 99 cases out of 100, those that use sweets rarely care for stimulants, and *vice versa*.

SELLING EXTRACTED HONEY LOW, AND WHY.

I have just received a letter from friend Baldridge, of St. Charles, Ills., in which he (in a friendly way, of course), scores me for selling extracted honey at retail at 10 cents per pound, and says that he gets 20 cents for all he sells, and that, if he had to take 10 cents, it would drive him out of the business; and he further states that it is more profitable to him to buy extracted honey at 5 to 8 cents a pound than to raise it. Now, I know that friend B. sells gilt-edged honey, and he has, besides, a very taking way with his customers, and he keeps the custom he makes, too, which shows that he deals fairly and squarely; but notwithstanding all this, I do not believe he could sell in my vicinity at any better figures than I do. My customers are mainly coal-miners, and laborers in large manufacturing establishments; and if you say to them 20 cents per pound for honey, they will laugh at you and do without it. A few will buy it at that price for colds, and to use as medicine; but as food, never. I have made it a point to go to every house, street by street; and if this article were not too long already I could give some pointers too, as to how to sell honey to those who think it too good, and too high priced for food.

You have to suit your prices to the class of customers you deal with; for there are some few who will pay any price asked, provided they get what they want. Another thing, too, is that no basswood and but little white-clover honey is raised here. Our chief source of honey is fall flowers, and it is necessarily more or less dark. Though Spanish needle and smartweed yield clear nice-looking honey of excellent quality, it is not gilt-edge or superfine, and must bring a lower price, both wholesale and retail, than the finer-looking grades of white clover and basswood raised elsewhere.

Belleville, Ill., Feb. 7. E. T. FLANAGAN.

[Friend F., your suggestion is good in regard to giving the children honey instead of candy. For the past four or five weeks we have been having excellent maple molasses, and I fear I have been using more of it than is conducive to my health. A day or two ago I thought I would substitute honey, and see whether it answered any better, and I was agreeably surprised that, when taken in considerable quantities, with its complement, a glass of milk, it seemed to be much more wholesome, at least to myself, than the maple syrup. Very likely both are nature's sweets, designed by God for human food; but the holy Scriptures lay very much more stress on milk and honey than on any other kind of sweet.]

MOISTURE IN BEE-CELLARS.

DOOLITTLE REVIEWS THE MATTER.

On page 877 the editor adds quite a long footnote to what I have to say about the dampness in my bee-cellar. On the whole he is perfectly right; but his reasoning does not fully apply to the cause of dampness in bee-cellars, as he will soon see, I think, if he will stop to think a little. As he says, the cause of moisture and water collecting in drops on any surface is that of warm damp air coming in contact with a cold or cooler surface than the surrounding air. From this he reasons that, at times when the outside air is warmer than the air of the cellar, this warm air will enter the cellar through the ventilators and thus cover the walls with moisture, making all damp and wet, and thinks it is for this reason that I do not have any ventilators to my cellar. Well, now, while this might be the cause of dampness in a bee-cellar once in a while, yet in 99 cases out of 100 it has nothing to do with it. Without any ventilators whatever in my new bee-cellar, the flagging cover and the painted door at the entrance have been running down drops of water on the inside all winter, and no air from the outside has been allowed to enter. The reader will remember that, at the front end, this cellar is 3 feet under ground, while at the back end it is 9 feet. Well, the air which comes from the back end of this cellar, or, perhaps I should say, the air warmed by the lower back end of the cellar and the breath of the bees, together with the heat from their bodies, is warmer than the flagging overhead or the door at the entrance, which are affected by the cold and frost from the outside, so that, when this warmed air comes in contact with these cooler surfaces, the moisture from it is condensed on them; hence the moisture is continually trickling down on the inside. It is to be remembered that the three feet of earth between the two roofs is kept frozen the most of the winter, or the upper half of it at least, and this is the reason, or one of the reasons, that the temperature of the cellar does not vary one degree inside, although the outside temperature may vary from 30° below zero to 60 above. When it comes more steady warm weather, during the latter part of April, then I have things reversed; for at that time the inside of the cellar is cooler than the dirt and temperature outside; hence the moisture now condenses on the outside of the door and flagging. Am I not right, friend Root?

SUNDAY PLANNING.

It was with great interest that I read the article by friend Miller on "Planning," and your comments on the same, especially that part which touched on planning during Sunday and while in church listening to the sermon. Friend Root seems to think that Satan has *all* to do with it, but I think *not* all. There is a great difference in speakers, or in the way they present the truth. I have sat in church trying to follow a sermon which was presented so dryly, and in such a sleepy way, that I had to use all the powers which I was possessed of to keep my mind on the discourse, at least half of the time; and, again, I have listened to sermons in which the truth was presented so pointedly and interestingly that I could not get away from it *one second*, even to think of some horse-trade or some other exciting thing that happened only yesterday, that was the theme of the whole community. While I have the highest respect for all preachers of the gospel of our Lord and Savior Jesus Christ, yet I have a lingering thought about me that some of them might be serving the master better between the plow-handles, over a bee-hive, or in other callings in life—preaching the word by their "daily lives and godly conversation," rather than trying to preach it from the pulpit. But, really, is it contrary to God's will to do any planning about temporal affairs on Sunday? If the Christian has placed his life and all his ways in the hands of God, willing to be led by the Spirit, and to use all of the things of this world which come to him for the honor and glory of God, so that all the success of his planning is to be put into the cause of the Master, may not his planning then be according to God's will? What is God's will? and what am I to think about on Sunday? About heaven and God in the way many people try to do? If so, then I feel a good deal like the heroine in "Stepping Heavenward," where she says she does not wish to "sit on a bench in a row with others, singing through all eternity;" yet this is about as high and enlarged views as most people have of heaven. Jesus went about doing good, healing the sick, lifting up the fallen, etc.; and he did this on the Sabbath as well as on other days, and he is our great Exampler; and if the outcome of our planning reaches out wide enough to take in all this, why say, "Not *another word* of it on God's holy day"? Oh for broader views and greater enlightenment along the road toward heaven! views that reach out till they can in some measure grasp the Infinite.

BASSWOOD.

If I am correct, Ernest says that the basswood is more luxuriant in growth here than it is in Ohio, and I have so understood by other parties. This being the case, imagine my surprise at seeing, on page 130, that you are receiving lumber cut from logs which have grown from sprouts from the stumps of basswood trees cut only ten years ago! I know basswood is capable of doing great things; but this is altogether ahead of me. Ernest spoke of the thrifty growth of basswood near my apiary, which has grown since the year before I came here, it being all cut off at that time (1874), yet there is not a stick in all this growth that is more than seven to nine inches in diameter, that growth taking 16 years. Some, further from the apiary, that are from 30 to 35 years old, are a foot to fourteen inches through, which might do to cut; still, it would be very wasteful to do so. Would it not be well to modify that statement a little?

Borodino, N. Y. G. M. DOOLITTLE.

[I grant, friend D., that these statements, when put side by side, look a little contradictory; but one fact, perhaps, you have overlooked. The trees which we referred to as having such a rapid growth, grew from the *parent* stumps, i. e., "on the old man's capital." The roots were, of course, strong, and gave the young shoot a tremendous boost, and it is not much wonder that they grew so rapidly. If I remember correctly, the basswood-trees which you showed me, and to which you allude in your article, grew from seed; i. e., they had to build up from *their own* capital. You will notice sometimes, that young locust shoots will spring up and grow with wonderful rapidity from the roots of an old tree; but they would not begin to make half that growth if they had to depend upon their own roots. The farmers who brought us the basswood lumber in question said they had cut it from the same roots from which they had taken lumber ten years ago. If your trees grew from the stumps of old trees, then, of course, I am unable to explain it; but I am sure that the trees of *natural* growth in York State are much more thrifty than those in Ohio.] E. R. R.

[I think you are probably right, friend D., in regard to dampness in the cellar; but in regard to Sunday planning, my test is this: When I plan greenhouses or other week-day matters, even though the sermon may be dry and dull to *me*, I feel a loss of spirituality, and conscience tells me that I am out of the straight and narrow path. Like yourself there are some sermons, or, rather, times, when it is no effort to follow the preacher at all; but sometimes Satan presses me sorely, even when *good* sermons are being preached. Perhaps my greatest temptation is to let my mind go running on some affront I have received. Then before I know it I begin to plan the letter that shall be written to so and so. Now, letting my mind go on such topics on the Sabbath does me harm, and I believe it is the Holy Spirit that tells me I had better listen with all my mind to the dryest sermon I ever heard, rather than to let my thoughts wander on week-day cares or enjoyments. Every sermon, as a rule, contains more or less Scripture texts; and if we listen to them, we shall be doing well. I agree with you, that Sunday should not be a *lazy* day; and when I have a good-sized class in jail (as I have now) I oftentimes do quite a little planning as well as praying in endeavoring to lead them to the Master.]

CLOSED-END FRAMES.

TESTIMONY FROM ONE WHO CONSIDERS THEM "UNBEARABLE AND ABOMINABLE."

Friend Root:—I am completely astonished at so many testimonies in favor of the closed-end or half-closed frames. I have tried them both in Texas and Cuba, and, to own up, they are simply abominable and unbearable; furthermore, I never have known any one to try them who did not get a hatchet and reform them at the first convenient time. They positively will not do here in Cuba, no matter how expert the operator may have become in a colder country. The main reason is, genuine bee-glue, or propolis, that abounds too abundantly, and of a superior quality. In reality, it is so good for glue that, when a colony is left gluing for half a year on a stretch, its frames can be removed only in pieces by a chisel; for, before the joints will separate, the wood will split away off in some other way, and leave the edges glued as firmly as ever at the joint.

As for handling the Hoffman frame rapidly, it, of course, could be done by a Hoffman-frame man; but I should feel shabby if I saw any man handle Hoffman frames as fast as the common frames (that are in general use) can be handled by a man who has had practice enough to work rapidly. Friend E. R., the reason you get only the Hoffman side of the question testified to is because so many like myself have such a contempt for a frame that kills bees and clogs up so, that they don't even care to give in their testimony. But it is now time that the other side of the question were being spurred up; for if it keeps as silent in the future as it has during the past six months, all the beginners will have Hoffman frames, and owe their thanks to

E. R. Friend Woodward's article on page 96 should be read the second time by Southerners who think of ordering frames for the first time, for bees don't generally build perfect combs, for beginners especially.

As far as spacing is concerned, when it comes to extracted honey the Hoffman frame has no advantage, for the simple reason that there should be one or two frames less in the top box, or extracting-super, than in the brood-chamber; for example, if you use nine frames in the bottom you want only seven on top to get the best result with the least labor. Now, how about changing frames from top to bottom without first scraping all the wax and propolis off the edges that didn't touch while in the extracting-super (a sharp hatchet scrapes them for me, and then it doesn't have to be done over again)? and I have friends who advocate the same plan at home, if not in print. W. W. Somerford.

San Miguel de Jaruco, Cuba, Feb. 15.

[That's pretty hard on the closed-end and Hoffman frame, friend S.; but this is what we want—a ventilation of *both* sides of the question, for all localities. Such adverse testimony is valuable. It proves that, in some localities, the propolis may be so bad as to make closed-ends "unbearable and abominable." I have never said that these frames would please everybody. On the contrary, I have hinted pretty broadly all along that the loose frame would never be abandoned; that one frame would be used about as much as the other. Beginners won't be hoodwinked, as you intimate—they will take what their supply-dealer recommends them to; and that, at the present as well as in the past, is the loose hanging frame. Our standard frame, the frame that is sent out in hive combinations, is the loose L. frame. For *special orders* only, we send fixed frames; i. e., closed-end or Hoffman, and generally those are in small lots for "samples to test."

It may be you haven't acquired the knack of handling these fixed frames; still, I should more think your two localities wouldn't admit of their use on account of the extra amount of propolis. Dr. Mason insists that closed ends wouldn't do for him. But all this doesn't argue that there are not a good many other bee-keepers who can use them. No, I won't take back one word that I said in favor of them where I saw them used successfully. In many hands they are a grand success. If propolis is so bad with you, I don't see how you can use sections or even wide frames. Why, they would be stuck together so badly that you would have to use a hatchet to pry them apart. If that is the case, of course you couldn't use closed-end frames. See p. 208 for the "other side."] E. R.

A CHEAPER METHOD OF MELTING WAX.

HOW TO CONSTRUCT A WAX-BOILER OUT OF WOOD, WITH A TIN BOTTOM.

After reading E. France's experience in melting beeswax I feel inclined to give your readers an account of a much cheaper boiler that answers the purpose very well. I have been using for some years, for a wax-rendering boiler, a wooden box about two feet square and one foot deep, with a tin bottom. The box was made several years ago, as part of an outfit for making foundation on plaster-of-Paris casts. It is made of pine lumber; and in order to get the corners water-tight, the end pieces are let into gains or grooves, across near the ends of the side pieces, and well nailed. The tin bottom should be about an inch larger all around than the outside of the box. To put the bottom on so that it will not leak, paint the bottom edge of the box heavily with thick white lead and oil, before nailing on the tin. Then turn up the projecting margin of tin and tack it securely to the wood, having previously used a liberal supply of white lead in this joint also.

The box, or boiler, is used on an old cookstove in the shop. The combs and cappings are put into a sack of strainer cloth. And I may remark here, that a large bulk of combs can be put into a moderate-sized sack when the lower part of the latter is immersed in boiling water. After the comb is all in and much of it melted, the sack should be tied up, and a slatted honey-board placed over it. This can be kept down under water, and a strong pressure brought to bear on the sack of comb by the use of a small pole or prop cut just long enough so that, when one end is pressed down firmly on the honey-board, the other end will rest against the ceiling above. At this stage of the proceedings, if the water is boiling I remove the fire from the stove, as a precaution against the wax boiling over, and leave it to cool. The wax can be remelted in more clean water—the more water the better—and allowed to cool slowly, if a very light color is desired.

Farina, Ill., Jan. 6. T. P. Andrews.

[We used to employ the same method of melting wax in a common second-rate wash-boiler. A boiler could be made in the way you describe, and such a receptacle would be a capital thing in which to scald foul-broody hives. A boiler made entirely of tin, and large enough for the purpose, would be rather too expensive.]

GERMAN CARP AND CARP-PONDS.

SOME INTERESTING FACTS.

Every pond should be so arranged that the whole of the water can be drawn off, not leaving a gill in any one place. The water should be drawn yearly, between Dec. 1 and April 1, taking out every fish, frog, tadpole, etc. Young carp a year old will eat the fish-eggs; after this, instinct teaches them not to eat them; hence, breeding-fish should be kept by themselves. The large tadpole that lives through the winter is a dear lover of fish-eggs, and will leave but very few to hatch. From three pair of breeding-fish, at two years old, in 1886, I got 1500 young; and as I had more grass around the pond, and these fish got larger, I had more and more young fish, until in 1889, it was an innumerable multitude. Because of sickness in 1890, the pond was not drawn off till June, and not a single young fish was seen. This utter failure was wholly chargeable to the large tadpole. I have three ponds — one for breeding, one for those I wish to eat, the other for small fry. Last year one pond stood all the year without water. This year it will be equal to a new one, and another pond will go dry this year, etc. One acre of new pond is worth as much for growth of fish as four acres of three or four year old pond. I can not agree with my friend that his fat carp were made so by preying upon other fish. It was another breed that had eaten the young fish. All the millponds, creeks, and rivers in this country are getting well stocked with carp from broken carp-ponds, and many of them are very fine, weighing from six to ten lbs. or more. It is very pretty to see the young fish eating biscuits and light bread thrown to them after they have been trained awhile. Hundreds may be seen at a time, reminding me of bees swarming. Selling fish for stocking other ponds has more than paid all

cost. But to raise them for food purposes could hardly be made a paying business unless the ponds were very large, and could be rested every other year. N. Jef. Jones.
Design, Pitts. Co., Va.

[We have given place to the above principally because it speaks of the fact that the German carp is now to be found generally in our brooks and mill-ponds. If this is true, then the work of the fish-commissioners, in scattering German carp throughout our land, has been a good one. Inasmuch as we have published a book on carp culture, and there is a periodical devoted to the subject—namely, *National Journal of Carp Culture*, Alliance, O., we think we shall have to devote our space to other subjects for the future.]

OUR QUESTION-BOX,

With Replies from our best Authorities on Bees.

Question 180. *Please tell how much ventilation bees need when wintered outdoors, and how you would secure it.*

We leave the full fly entrance open.
Illinois. N. W. C. Mrs. L. Harrison.

The entrance is all the ventilation they need.
Louisiana. E. C. P. L. Viallon.

Just how much they need is a question I am not prepared to answer. I have had them winter well with *much* and also with little.
Vermont. N. W. A. E. Manum.

Only that from the usual opening, and this should be restricted when very cold. To secure this, keep dead bees out.
Michigan. C. A. J. Cook.

We remove the cloth and use a straw mat over the frames, with absorbents in the cap or upper story. We give but little lower ventilation.
Illinois. N. W. Dadant & Son.

I never winter outdoors. If I did I believe I would put a two-inch rim between the hive and bottom-board, and close up tight, but open the entrance when warm enough for the bees to fly.
Ohio. N. W. A. B. Mason.

We leave, at the bottom, six ⅜-inch holes open all winter, just the same as we have in summer. In summer we have a 1½-inch hole through the front side of the hive, half way up. That hole we close in winter.
Wisconsin. S. W. E. France.

I don't know. I'm trying four outdoors, pretty well covered up, all but the entrance, and that's 12x2. Ought to kill them, oughtn't it? Likely it will. But then, I can say it's the climate.
Illinois. N. C. C. Miller.

I have wintered outdoors successfully several winters, with no other ventilation than the summer entrance, which was ⅜ inch high across the front of the hive, and again lost heavily with the same treatment.
Wisconsin. S. W. S. I. Freeborn.

We abandoned outdoor wintering some years ago, consequently we are not up to the times on this subject. I am under the impression, however, that they do not need nearly so much as is usually given them.
New York. C. P. H. Elwood.

I have had excellent results by placing a rim under each hive, having an air capacity of about 500 cubic inches, and giving them a generous entrance. A close-fitting cover is on the hives, but no rags or quilts.
New York. E. Rambler.

About the same as in warm weather, on the summer stands, and secured in the same way by having the entrance wide open. I think favorably of an empty chamber below the combs for wintering out of doors as well as in.
Ohio. N. W. H. R. Boardman.

I ventilate by an entrance ⅜ by at least 8 inches long—usually the full width of the hive. If upward ventilation is allowed—*I* want none of it—the entrance should not be so large. The hive should be air-tight on top, entrance large, and hive well packed on all sides.
Illinois. N. C. J. A. Green.

Make the entrance ⅜ by 12 inches. Lean a board up over the entrance, so that no cold winds nor the sun can beat in at the entrance, also to keep snow and ice from forming there, and you will have things fixed about right, according to the opinion of Doolittle.
New York. C. G. M. Doolittle.

When I have seen many colonies of bees winter nicely under a snowdrift in old box hives, with no opening except three or four little triangular notches sawed in the bottom of one of the side boards, I do not know why a gimlet-hole will not give air enough, and that may be in the top, bottom, or side of the hive. I have seen much of ventilation, but I do not know much.
California. S. R. Wilkin.

I never could discover that bees needed any ventilation, in doors or out. At present I have over 60 colonies, of my 350, in a cellar which is half full of honey barrels and kegs, and I close it up tight without any ventilation whatever, only as I open the door to go down and see how they are coming on. This winter they are extremely quiet, and appear to be wintering perfectly. Bees flew lively outdoors yesterday, December 22, the shortest day in the year.
Michigan. S. W. James Heddon.

Very frequently I secure it by leaving the entrance just as it was through the summer. I like pretty well to put a special bottom-board under for wintering, which gives two inches more space below. This space is filled up with dry sawdust, except a little in front. In front there is an open chamber about 2x2x6, closed from the outer world by a movable block. Between the block and the corner of the bottom-board there is a vertical entrance, two inches high by three-eighths wide, and fenced against mice by a row of wire nails.
Ohio. N. W. E. E. Hasty.

Confine your bees to the brood-chamber, which cover with a board or boards, a honey-board, or something like it. Keep these boards warm by putting on a straw mat or its equivalent, because the bees cluster below, and would chill without this precaution. Have plenty of honey in your combs, with the heaviest toward the center, and a winter passageway through every one; full width of the entrance open, with a two-inch strip under the back of the hive, so that all moisture is bound to run out; otherwise it will be absorbed by the combs, sour the honey and pollen, and create dysentery.
Ohio. S. W. C. F. Muth.

[From the above, the general tendency seems to be giving at least as much room in winter at the entrance as they have in the summer time: and, if any thing, rather more. To all this I agree, only that I would not allow any sort of entrance that would permit mice to get in. I do not believe it will pay to undertake to contract and enlarge entrances as the weather changes. We once tried it on quite a good many chaff hives; and those that had the entrance open full width all winter, long did a good deal better than where any kind of contraction was practiced. A very small entrance will, of course, answer, providing the bees have upward ventilation—leaving the surplus arrangements on all winter, and such like arrangements. Friend Green is very emphatic in saying "the hive should be air-tight on top." Well, I think likely he is right, providing the entrance be large enough, or that there are other large openings through the bottom-board. Several mention having an empty chamber under the brood-combs. I am inclined to think this is a very good arrangement where you have movable bottom-boards. I rather think that ordinary cellars or caves will answer very well without any special arrangement at all being made for ventilation, and a great many bee-hives will also have all the ventilating cracks and holes that can be needed. There should, however, be some opening for bees to pass in and out whenever the weather is warm. With a loose, poorly made hive, if this opening is sufficient to let one bee pass, and does not get obstructed, it will do very well.] A. I. R.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

SHALL WE CONTINUE TO SEND GLEANINGS IN BEE CULTURE?

No, don't. I've got enough. The contributions of some of the writers for GLEANINGS are good, and with them I find no fault; others I do find fault with—Rambler, for instance. The Home talks are obnoxious. To take a passage of Scripture, and branch off on to such boasting about a $400 team, a big factory, and so many hands to see after, and so much property, and me and mine, and big I, doesn't suit me.

Burnville, Ark., Dec. 22. H. C. M. BRALEY.

[Well, good friend B., the above would be rather discouraging, to be sure, if it were not for the great flood of *approving* letters that come in every mail; and, besides, there is another encouraging thought—you put our good friend *Rambler* down with the author of the Home Papers. I always *did* like to be in good company. Joking aside, however, I want to thank you for your criticism, even if it be very plain and rather severe. It has many times occurred to me that those who do not feel especially friendly might look at my Home talks in just the way you have. I did not mean to boast of our big team. I simply wanted to encourage the idea of having horses adequate to the work to be performed, and giving them good care. I do believe that many of our farmers would accomplish more, and do it *cheaper*, by having heavier horses, well cared for; and instead of the big "I" it was and *is* my purpose to exalt only Christ Jesus. The Home Papers, with all their imperfections (and I see them as plainly, I believe, as almost any one does), have been the means of doing good, through Christ Jesus, and to him alone be all the honor and praise. My old pastor, in his prayer one Sunday morning, said, "O Lord, we thank thee for our enemies, because they tell us our faults when our friends will not." Now, dear brother, I do not want to consider you as an enemy as we bid you good-by. On the contrary, may God speed you in all that is good and pure and holy. May be we shall become better *acquainted* some time; and I hope and pray that we may both become better men as the years go on.]

HOW TO KEEP DRIED FRUIT FROM THE MOTH AND MILLERS.

Mr. Root:—We have had a great deal of trouble every year in keeping dried fruit from the millers, or moths. We should like to hear through your valuable paper how to keep the fruit until spring from becoming wormy. We have been keeping them in barrels lined with paper, and tightly covered, but have not had any success. We are thinking of trying a new plan of putting the fruit, first in a burlap sack, then slipping it loosely into a bag made of oil cloth. We should like to hear the experience of some of the readers. BYRON H. WILEY.

Fillmore, Cal., Jan. 27.

[We sent the above to Prof. Cook, who replies as follows:]

If Mr. Wiley will put his fruit in paper sacks and then tie tightly, he will escape the insects surely, unless the eggs are laid before the fruit is put into the sacks. He says he puts his dried fruit in barrels lined with paper, and yet suffers loss. I think in this case the female moths lay their eggs on the fruit before it is put into the barrels. In such cases, if a small hole were bored in one end of the barrel, and tightly corked, it would be easy to free the apples or fruit of insects by use of bi-sulphide of carbon. Withdraw the cork, turn in half a pint of the liquid, and quickly cork up the hole. The liquid would destroy the insects, and would do no harm to the fruit. This would be a very cheap and convenient cure for the evil. It should be remembered that this liquid vaporizes very quickly, and that the vapor is very inflammable, and very explosive when mixed with air. In this case the barrels could be easily moved out of doors, or be kept in a room where no fire or lighted cigar, etc., is ever taken. I would use paper sacks for storing, and, in case of attack, I would use bi-sulphide of carbon to destroy the mischief-makers. Bi-sulphide of carbon very soon escapes if permitted; and it is so odorous that its presence, even in very small quantities, is sure of detection. It volatilizes so completely, that, even if thrown into a flour-bin, it all evaporates and the flour is uninjured. A. J. COOK.

Agricultural College, Mich., Feb. 6.

RAMBLER'S VISIT TO THE BAY STATE APIARY.

Friend Root:—I have read Rambler's visit to the Bay State Apiary with a good deal of interest. As you seem to have a wrong impression regarding some things, I will try to correct them. I judge by your foot-notes to Rambler's article that you have an idea that I am an inveterate smoker as well as Bro. Pratt. You are wrong in this. I do not use tobacco in any form, except to introduce queens. Although I use several pounds each season of the vile weed, it always has a bad taste to me.

You want to know whether we did not get the "plantain leaf" idea from you. Guess not. We have used it nearly 30 years, and used it, friend R., when you used to send orders to the Bay State Apiary for queens. That, I believe, was a good many years before you published a bee-paper. I give you a cordial invitation, friend R., to visit the Bay State Apiary whenever you can find it convenient to do so. You will see and hear about a good many things that have not been seen in print. You need not look for Alley in a bar-room, nor will you find him in the shade of a tree sucking an old pipe.

Say to Rambler that there is fourteen months difference in the ages of the "twins" he has pictured "eating" honey. These two little queens take a good deal of my time. They get "grandpa" up pretty early in the morning—a good deal earlier, sometimes, than he wants to get up. H. Alley.

Wenham, Mass.

[We are exceedingly glad, friend A., to know that you are not a tobacco-user. Perhaps I got my wrong impression from the fact that some one mentioned your using large quantities of tobacco in smoking your bees. We are glad to know that you are on our side of both kinds of temperance—whisky and tobacco.]

SOMETHING FOR FLORIDA BEE-KEEPERS.

As we bee-keepers in Florida have no paper that reaches, perhaps, more bee-keepers interested in making an effort to prepare for an exhibit at the World's Fair at Chicago than Gleanings, if permissible I should like to hear personally from each Florida reader who is a bee-keeper, as to what he thinks of forming a State Bee-keepers' Association at as early a date as possible, to meet at the capital of the State some time during the session of the legislature, so that, if possible, we might prevail on it for some assistance in making and caring for such an exhibit; and further, to state what amount of honey and fixtures you each could prepare for exhibition. We shall certainly have to unite, first, in a State association of bee-keepers before we can arrange for an exhibit that would call forth any thing like the resources of the State. I should like to hear the views of all the Florida bee-keepers in this matter. It is none too soon to begin the preparation.

John Craycraft.

Aster Park, Fla., Feb. 28.

FEEDING BEES ARTIFICIAL POLLEN WHILE IN THE HIVE; AN INTERESTING CASE.

It seems as if we were going to have a late spring, and a bad time for bees to carry in pollen; and why not take a hint from the following circumstance and put flour on the top of the hives for pollen? My father is 80 odd years old, and he told me that one of his neighbors, some 70 years ago, set a log hive of bees in an old barrel half full of wheat, to keep them out of the cold; and when he took them out of the barrel in the spring they were all right, and had eaten the wheat under the hive until the bran was two or three inches deep.

J. D. Whittenburg.

Marshfield, Mo., March 3.

[Friend W., your story sounds pretty strong, and yet it may be true. When bees are destitute of pollen they will take hold of a great variety of substances; and as they eat wheat flour with avidity when put out in the open air, it is possible that they learn how to dig the flour out of the wheat and thus raise brood.]

PAINTED CLOTH AN EXCELLENT SUBSTITUTE FOR TIN.

I see there have been some inquiries in regard to painted cloth for hive-covers; and not seeing any thing from any one who has used painted cloths, I venture to give my experience with it. Four years ago I was making some chaff hives; and not having lumber wide enough for half the roof, I used narrow boards and painted them. Then I tacked on some Atlantic A sheeting on the green paint, then painted the sheeting. I have painted them once since. They have been exposed to the weather, winter and summer, ever since, and I consider them good for a good while yet, so far as the cloth is concerned. In these times of high tariff on tin, I think it would be well for those who use tin for hive-covers to try a few cloth ones and keep them painted. If they do, I think they will be pleased with the result. I also believe it would make a better roof for dwellings than a good deal of this roofing that is advertised. If Dr. Miller will try painted cloth he will find it far superior to oil cloth. John Anderson.

Oriskany Falls, N. Y., Feb. 28.

[You have given just the fact we wanted. Now, who else can testify? So far the evidence shows that painted cloth will answer. But the great thing in its favor is cheapness, tariff or no tariff. Painting the wood first, before the cloth is tacked on, might have the effect of gluing it so firmly to the wood that it would be less likely to receive tears or injury.]

MICHIGAN APIARIES; STATISTICS FOR 1889-'90.

According to the Michigan Crop Report of Jan. 1, 1891, the farm statistics for 1889-'90 returned last spring by supervisors furnish the following figures: The number of apiarists in the State in the spring of 1890 was 5903. The number of colonies of bees on hand in the fall of 1889 was 77,602, and the number at the time of taking the assessment last spring was 68,404. The number of colonies wintered in cellars was 17,169; in chaff hives, 28,424; in bee-houses, 566; covered with sawdust, 316; otherwise protected, 1810; with no protection, 21,987; protection not reported, 7330.

In 1889, 68,440 colonies made 1,192,112 lbs. of comb honey, and 23,349 colonies produced 271,564 lbs. of extracted honey. The number of lbs. of wax produced in 1889 was 9625.

Compared with the statistics of the previous year there is an increase of 1416 in the number of apiarists; of 23,744 in the number of colonies on hand in the fall, and of 22,891 in the number on hand in the spring. The quantity of comb honey produced in 1889 was 632,310 lbs. greater than reported for 1888, and the quantity of extracted honey was 173,964 lbs. greater in the latter than in the former year.

Concord, Mich. Manly Shotwell.

[There (if reliable, and we should think they were not far from right), these statistics are interesting and valuable. What is the reason that other States don't do likewise? If they did we could then know pretty accurately the number of colonies, etc., in the United States. On an average, then, each Michigan bee-keeper owned, in 1890, 13 colonies. In 1889 he secured on an average, from each colony, 17 lbs. of *comb* honey and 11 lbs. of *extracted* per colony, or 28 lbs. of honey in all; but 1889 was a rather poor season all over the country, especially for Michigan.]

THICK TOP-BARS USED SUCCESSFULLY FOR EIGHT YEARS.

There has been considerable said in Gleanings for and against heavy top-bars. I will give you my testimony in favor of them. When I commenced bee-keeping I made twenty-five hives, all with heavy top-bar frames. With the increase of my apiary, and other work, I did not have time to make the hives I wanted, so I ordered 30 Simplicity hives, so I had two kinds of top-bars. The heavy were ⅞ by 1 inch, spaced 1⅜ from center to center, with ⅜ space between frames and super. I used it six seasons and never was bothered with burr or brace combs. The light frames were spaced the same; and when I took the super off the first hive, the whole of the brood-chamber came with it. In taking off some of the supers I had to lift them up with one hand, and pry the frames loose from the super with a screw-driver. W. J. RUSSELL.

Philmont, Kan., Feb. 8.

[You have given one valuable point; viz., with thick top-bars one inch wide by ⅞ inch thick, even with as large a bee-space as ⅜ inch, no burr-combs will result, even after 8 years. We now know that, by reducing the bee space to a scant quarter-inch, and using fixed distances, top-bars as thick as ½ inch will do, or possibly less. Let those who do not like those extra-thick bars, use a lesser bee-space and note the result.]

REGULATING SPEED BY THE SLIPPING OF THE BELT.

On page 33 you give the experience of one of your boys in changing the speed of machinery. Is not that plan rather hard on the belt, as the change in speed must be caused by the limited amount of belt contact with driver? The driver being constant, the belt speed must be the same, or nearly the same, and the loss in speed must be due to the slip and consequent greater friction on one edge of the belt, which would mean a shorter life for the same; and while it might answer for a temporary expedient it would look to a man in the woods as though the true economy would result in putting in the cones. A. R. KIBBE.

New Richmond, Wis., Jan. 7.

[We have regulated the speed on one of our presses—a small one—with a slipping belt, as described in GLEANINGS, for over 10 years, and the same belt is in use yet. We have adopted the same arrangement on a larger platen press —a half-medium—with entire success. The secret lies in the fact that low speed and small power are required. Cones would certainly have to be used where something over one-horse-power work or high speed is required, or on lathework for screw - cutting. For small presses the slipping of the belt answers perfectly.]

A LADY WHO NOT ONLY DOES NOT WEAR GLOVES, BUT WORKS AMONG THE BEES WITH BARE HANDS AND ARMS.

I see in GLEANINGS that you wanted to hear from other ladies who work among the bees. I put on a hat and veil, push my sleeves up as far as they will go, so the bees can't go up inside of them. They are not so apt to sting my arms with my sleeves up as with them down. A few stings on the hands and arms will get well anyhow. I don't wear gloves, for I want my hands free from any thing of the kind.

I think if Miss Wilson will get some heavy jeans and make an apron, the honey will not run through and soil the dress. It might be "bunglesome" and warm. I do all kinds of work that are done among the bees, and help put up supplies; in fact, every thing but nailing up the hives. I do almost all of the painting and all of my housework—washing, and every thing. I have four small children to tend to. MRS. S. D. COX.

Washington, Ind., Feb. 20.

[Very good, Mrs. C. I, too, should prefer to have my hands and arms bare of every thing, providing I could work with bees when they are gathering honey, and every thing is peaceful and quiet. One who sells bees and queens, however, and is therefore obliged to overhaul hives both in season and out of season, could not well manage in the way you suggest.]

ANOTHER CLAM-SHELL IDEA; USING SHELLS INSTEAD OF SLATE TABLETS.

My plan for keeping record of bees is to use two half clam-shells instead of a slate. I keep one on the front of each hive, in which I write the age of the queen and such other data as I want to go into my book. In the other, on the back end of the hive, I write work done and when, condition, etc. I use a leadpencil, and when a shell is full I pick up another, or rub out with a wet cloth or sponge, and begin again. I live immediately on Lemon Bay, where clams are more plentiful than any thing else (unless it is fish), and clam-shells are not expensive. They are not flat, like a slate, being rounding, but are just as smooth inside, and as nice to write in. I turn the flat (or open) side down, which lies snug on the hive-cover, so that no water nor any thing else can get under them. They are light, not much in the way, not easily knocked off, and are rather pretty than otherwise. J. H. HILL.

Venice, Manatee Co., Fla., Feb. 21.

WHY JAPANESE BUCKWHEAT IS SUPERIOR TO THE SILVERHULL.

I find the Japanese buckwheat superior to the silverhull. After a trial of three seasons I have concluded to sow no other kind. One great advantage it has in this country is, that we can raise a crop early in the season, and the bees have the benefit of the blossoms when they need them so much. In the fall they do not work so much on it because they seem to prefer to gather from heartsease. I raised two crops last season—light crops, of course, on account of dry weather, but it proves that the season is long enough to raise two good crops if there is enough rain. The common kind did not fill any earlier in the season. It will also make more flour per bushel. The miller said it was softer and ground finer. There is, however, one drawback—it is not inclined to grow as tall as the other variety. J. T. VAN PETTEN.

Linn, Kan. Feb. 10.

A SMALL YIELD OF JAPANESE BUCKWHEAT, BUT REMARKABLE UNDER THE CIRCUMSTANCES.

My Japanese buckwheat made only ten bushels to the acre, but I thought that was good, for it never had a drop of rain after being sown until cut. My bees did fairly well, but it was so dry they kept the drones all killed off. Such a thing I never saw, and I almost had a notion to accuse the honest little fellows of killing some of their *queens* in the terrible dry spell. I lost ten or twelve for some cause, and had to give them brood and eggs three times. It seemed as if they would hatch a queen all right; but they did not get fertilized.

Wichita, Kan., Feb. 9. EDWARD HIATT.

ALSIKE VERSUS OTHER CLOVER FOR WITHSTANDING FROST.

My alsike clover came through in good condition last spring, while seven acres of June clover, sown in the same field, in another part, mostly heaved out. It was all on the same kind of ground, and sown at the same time, under the same conditions. Alsike grew too rank for seed. It produced two tons per acre.

A SPORT FROM JAPANESE BUCKWHEAT.

Bro. Root, I have something new to tell you in regard to buckwheat, which will surprise you. When I was cutting the acre of buckwheat I grew from the half-bushel of Japanese I bought of you in 1888, I found one enormous plant, different from the rest, the straw being a little lighter in color, with more than twice as much grain on it, apparently a hybrid. The berry was darker than the regular Japanese. I saved it separate, and got 3500 from this one plant, while 1500 was the very most I could get from any one of ten of the Japanese. I discarded all the rest. I sowed it by itself in 1889, and harvested one bushel. I sowed that on two acres, away from any other, and harvested 100 bushels. Inclosed find sample, which I have named Martin's Prolific. I will sow no other kind another year. **Wm. Martin.**

Cass City, Mich., Dec. 26, 1890.

[I will say to our readers, that friend Martin wished to sell me the seed mentioned above. I advised him, however, to offer it for sale at a moderate price, and let the readers of Gleanings test it on a small scale. If it is really superior to the original, it will soon make itself known.]

JAPANESE BUCKWHEAT.

I think the Japanese Buckwheat takes the lead of any other variety. I bought four pounds of you last spring, and sowed it on an eighth of an acre, and harvested from it this fall 6½ bushels. Who can do better? It was sown on loamy land, greensward, with a light sprinkling of manure. **P. W. Smith.**

West Braintree, Vt.

EIGHT VS. THE TEN FRAME L. HIVES FOR THE ROCKY MOUNTAINS.

May I ask through Gleanings whether eight-frame hives are satisfactory in the Rocky Mountain region? The length of time a colony must depend on its stores extends from September to the middle of May, and I am of opinion that stores less than can be made in a ten-frame brood-chamber will not last through; and that these, being short, the breeding will be correspondingly limited. My own experience is, that the largest hives yield by far the greatest amount of super honey in the season. I should like to know whether this is exceptional in Colorado and the Rocky Mountain district generally. **J. A. Ferguson.**

Loveland, Col., Feb. 10.

[There are some localities where the 10-frame L. hives are better than the 8-frame, though for the great majority of localities the smaller hive is preferable. It can, of course, be made larger by adding another story. The 8-frame hive would be the better one for most localities among the Rockies.]

THE IMPORTANCE OF KEEPING COLONIES FED UP JUST BEFORE THE HARVEST.

I made a blunder last spring, there being no bloom for the bees until clover. I fed a good deal, but not enough. In colonies not having enough feed, the queens quit laying in some ten days before clover came. Colonies that had plenty of feed, gathered, some of them, as high as 80 lbs. to the colony, while others that had not the proper amount of feed hardly gathered enough to winter on. **L. H. Robey.**

Worthington, W. Va., Feb. 20.

BEES EATING LARVÆ AND EGGS, AND THE REASON WHY.

I noticed in Stray Straws, by Dr. Miller, that he is puzzled about bees eating eggs, and the remedy for it. Last fall, a few days after the first heavy frost, I examined my bees and found that the weak colonies that had been raising brood had eaten the white larvæ, but I saw no traces of their having eaten any thing else, because I did not look further. Each larvæ was about two-thirds eaten; the rest were disappearing later. *Cause.* It is evident to me that they were surprised by the cold, and concluded to get rid of the brood by eating it up, as they could not keep all of it warm enough to hatch, and possibly to use it for food. I noticed that only the brood around the outside of the brood-chamber was eaten, and the entrance entirely open, letting all the cold wind in. I afterward started them to laying by almost closing the entrances and feeding. Don't you think they would eat up bee-eggs under similar conditions? Dr. Miller did not state at what time of the year he would expect the eggs to disappear, nor when the queen was taken away. **Geo. E. Fradenburg.**

Kansas City, Mo., Feb. 23.

THE DOOLITTLE METHOD OF QUEEN-REARING A SUCCESS IN CALIFORNIA.

We are rearing nearly all our queens from the artificial cups, and, as a rule, have from one-half to four-fifths of them built out in good shape. We are not having as good success with them this spring as we did last summer and fall; but we hope feeding will make it all right soon. We may report results a little later, as we are a little short of queens for the early orders, and are rearing all queens by the grafting process in upper stories, and count on getting most of them by using the cups. Friend Doolittle also spoke of its being hard to get a queen mated from an upper story unless there was a good honey-flow. We had one mated in November, but she was in a third story, there being two queen-excluders between her and the laying queen below. **H. P. Luther.**

Redlands, Cal., Feb. 16.

YOUNG BEES IN SUPERS REMOVED.

I should like to ask, when you take off surplus and carry it three or four rods to get out the bees, what proportion of them will be young bees that never will get back to their own hive? **J. B. Whiton.**

Ithaca, Mich., Jan. 13.

[Friend W., I should say there might be ten per cent, possibly twenty, that would not find their way back. If there are other hives around, however, where they can hear the bees humming at the entrance, these young bees will get into them, and will perhaps do nearly as much good there as in their own home. I think, however, I should prefer letting them go back where they came from.]

ASBESTOS PAINT FOR HIVES.

In Gleanings for Feb. 1, page 107, we see an article cautioning us against a paint made by the Indiana Paint and Roofing Co. Have you ever known any thing of a paint known as asbestos, as to how it compares with lead?

Buffalo, N. Y., Feb. 9. **A. W. Lindsey.**

[We have heard the asbestos paint talked about, but can not now remember whether it turned out favorable or not. Perhaps some of our readers can tell us about it.]

HIVES FOR HATCHING CHICKENS.

I should be pleased to learn through Gleanings whether any one ever used a hive of bees for the purpose of hatching chickens, or am I the first who discovered it, or "hatched" the idea—which? **George James.**

Willoughby, N. S. W.

[Yes, some of our neighbors have been using some of our old hives, too old for bees—which we sold them cheap for hatching chickens. They reported that they were just the thing.]

PAINTED MUSLIN FOR HIVE-COVERS; AN ILLINOIS MAN SAYS HE HAS USED IT FOR FOUR YEARS, AND WANTS NOTHING BETTER.

In GLEANINGS, Jan. 15, you want to know whether painted muslin on covers of hives will be as good as painted tin. For 4 years I used painted muslin on my hive-covers; and my experience is, that you can find nothing better. It keeps the inside of the hive dry in any kind of weather. Paint and muslin will stick to the wood during the severest cold or warm weather. You never want to re-cover the hive; but every two years give it a coat of paint. But it will be better, where, instead of nailing, the muslin is pasted on the cover. Put the paste on the cover, then lay the cloth on; brush over with a hand-broom; cut the sides off with a sharp knife before they are dry; and, when dry, give two coats of paint. The same can be done with outside winter cases. I have muslin on the roof of my honey-house, and partly on my hen-house.

And now, friend Root, let me make a suggestion about muslin on warm or cold bed-frames. You have several objections to muslin-covered frames, and you are quite right so far; but if, before you nail the muslin on the frames, you nail a piece of poultry-netting (say four-inch mesh) on, muslin over the netting, it will not make the frame much more expensive or heavy—just heavy enough so that it can't be blown about; and during a rain the cloth will not form a water-basin in the middle. I am going to try it this spring; and if you think it over you will perhaps do the same.

HENRY SCHWERDTFEGER.

Lincoln, Logan Co., Ill., Feb. 3.

OLD KEROSENE-CANS FOR CALIFORNIA HONEY, AGAIN; A HINT TO CALIFORNIANS.

I see by GLEANINGS that the honey-producers of California are complaining that buyers of their extracted honey want new cans. Let me tell them how old cans lost them one sale. I sold nearly all my honey by Nov. 15, and wrote to a commission house in Philadelphia for white-clover extracted honey. I said I preferred eastern clover to what they called California white clover. When it came it was in old rusted tin cans, and they had the word petroleum stamped in the tin on the top. No names nor marks were on the box. The honey was light amber, but had an ugly taste. I couldn't eat it, and would not offer it for sale. I returned it. The color was such that the honey should have been good in flavor.

About how many pounds of paraffine wax will it take to wax a barrel, one head out?

Pottstown, Pa. W. W. KULP.

[These old square 60-lb. kerosene cans have done a great deal of damage to California honey—not that *all* California honey is tainted by a trace of kerosene; but the fact that *some* is, operates against the honey put up in new clean cans from the same State. The bee-keepers of California should either use new cans or else thoroughly cleanse old cans with an alkali, as explained in GLEANINGS, page 71. Use for barrels, about 10 lbs. wax or paraffine. Of course, you will not need that much for a single barrel, but you need that much to keep hot while rolling the barrel about. While you are about it you can wax several barrels.]

SNYDER'S METHOD OF CARRYING BEES INTO THE CELLAR.

In Ernest's Notes of Travel for Feb. 1, Dr. Miller says he can not carry hives of bees into the cellar without bottom-boards, and Ernest admits trouble may come occasionally from hybrids. Now, if Dr. Miller or any one else will do as I do he will not carry those bottom-boards into the cellar, nor have any trouble from bees flying out. Let me first say right here, that I carry my bees into the cellar alone, as I have never found a man for a helper who was as good as I am alone. On a cool afternoon, when no sun is shining, I go to my hives, put a half-inch block under each corner, and in less than an hour they are in a good cluster. I then take my strap and hooks, pick up my hive and walk off with it to the cellar; and very often I have to raise the enamel cloth to see whether the bees are alive or not. In 7 years I have not had the least bit of trouble in putting them in or carrying them out. My bees are hybrids from the blacks, Italians, and Cyprians.

RUBBER GLOVES BETTER THAN ANY THING ELSE.

If Miss Emma Wilson *must* wear gloves, I would advise rubber by all means. We have used them in our family for 8 or 9 years, and like them better than all other kinds. Kid gloves or dogskin come next; I would not use buckskin, for the bees will sting them, and most of the time will lose their lives. There is but one fault with rubber gloves so far as I know; and that is, the fingers are too long. I like to use aprons when I am working with the honey, and I feel proud when I am covered from my neck to my slippers with a nice clean one.

Orion, Wis., Feb. 10. FRED. L. SNYDER.

A COLONY OF BEES WHICH SECRETE NO PROPOLIS.

I have an anomaly in the bee-line. I have a strong colony of hybrids whose mother is a pure Italian, if I can judge by the markings. The bees use, in a manner, no propolis. They gave me two well-filled 28-lb. cases, T supers, from white clover. These were removed at the end of the flow, and replaced by a super reduced to 14, which remained on until late in the fall. Upon neither was any propolis. On the first, the white clover, they were absolutely spotless; on the latter, removed in the fall, only a bare trace, not to be observed except by scrutiny. Query: May I expect a continuance of this good quality the coming season? If so, may I expect queens raised from this queen to furnish brood having the same peculiarity? I would attribute this to want of time by reason of the flow; but all other colonies in the yard found time to glue things pretty freely. We have an abundance of the coniferæ in this region.

Guys, Md., Feb. 2. WM. S. ADAMS.

[We hope that you will answer your inquiry yourself, friend A., by trying some queens from this non-propolis mother. Just as soon as you know the results, please communicate the facts at once to GLEANINGS. *We* should like to know whether it is possible to breed a non-propolizing race of bees. But, hold a minute! Those colonies that daub propolis worst are generally excellent honey-gatherers, and usually come through the winter in splendid condition. There is this much for propolis. It seals the hives air-tight—a thing quite necessary in the production of comb honey, and for successful wintering.]

ONE TON OF HONEY FROM TEN HIVES.

There was a great honey season here last year. I took one ton of honey from ten hives, and then had them in good shape for the winter. How is that for an A B C man? That is more than you have ever done; but I tell you it kept me busy all my spare time.

JAMES ROBINSON.

Buffalo, N. Y., Feb. 19.

QUESTION 175 RECONSIDERED.

Friend Root:—Your respondents to question 175 do not take into consideration cool falls or a cold climate like this, which very seriously interferes with the building of comb in supers. I have never been satisfied with my yield of comb honey from fall bloom unless the season was an exceptionally warm one. The bees will gather the nectar, and store it in the comb furnished them when they can not draw out foundation in supers. For this reason I am buying an extracting outfit, and will run my apiary for extracted honey after basswood closes.

THE HOFFMAN FRAME.

I shall order the Hoffman fixed frame, as I am thoroughly disgusted with the loose hanging frame in the Dovetailed hive. The division-board which goes with the frame is a necessity in every hive. Your addition of follower and wedge in the super will make it perfect, in my opinion. At our last State Fair there was not a good super on exhibition.

N. P. ASPINWALL.

Harrison, Minn., Jan. 7.

THE WISCONSIN CONVENTION.

I inclose a clipping from a Madison paper, showing a little of the business done at our convention, Feb. 4 and 5.

Officers of the Wisconsin Bee-keepers' Association have been chosen as follows: President, C. A. Hatch, of Ithaca; vice-presidents, T. E. Turner, of Sussex, and Ochsner, of Prairie du Sac; recording secretary, H. Lathrop, Browntown; corresponding secretary, J. W. Vance, Madison; treasurer, M. J. Plumb, Milton. The association decided to ask the legislature for an appropriation of $1000 to enable it to make a proper showing of Wisconsin honey at the World's fair, and otherwise advance the interests of the industry. It was also decided to secure the incorporation of the organization under the State Law.

You remember what a jovial time we had a year ago when you and Dr. Miller were with us. Our meeting this year was not as largely attended, nor was there the same enthusiasm. Our Wisconsin bee-keepers suffered a failure in crop last year, and doubtless many of them did not feel able to attend the convention. We had the great good fortune to have with us Mr. Thos. G. Newman, who made not a few friends for the Bee-keepers' Union, in whose behalf he addressed the convention. Notwithstanding the small attendance, we believe that business of great importance was transacted.

HARRY LATHROP.

Browntown, Wis., Feb. 11.

JAPANESE AHEAD OF ALL.

I now put the Japanese buckwheat ahead of all others. I sow it at three different times—June 15, June 21, June 29. I raised the largest yield from that which I sowed June 29. On 3 acres I sowed 1½ bushels of Japanese buckwheat, which I got of A. I. Root, and on the 3 acres I had 74 bushels, making 24⅔ bushels per acre. As to bee-pasture, they worked from sunrise till 10 or 11 o'clock P.M. I will raise no other.

J. S. BUIERS.

West Brownsville, Pa., Feb. 8.

ALFALFA FOR SORE THROAT, AGAIN.

Seeing in last GLEANINGS how good alfalfa is for a sore throat, I will say a peddler, who stopped this week, had a very sore throat. I fed him on the alfalfa honey, and it helped him at once. It works like magic. I tried it on myself yesterday, and it cured me at once. This certainly is a valuable discovery, and ought to be in the home of every family. My bees are wintering finely so far.

EDGAR BRIGGS.

Manchester Bridge, N. Y.

A GOOD REPORT FROM CALIFORNIA.

Bees are a new thing to me, as I never had any thing to do with them till last April; then I had one swarm enter at one side of a cracker-box. The year before, the bees and I had made an agreement, that, if they would let me alone, I would let them alone. We kept that compact till last April, when I transferred them to a frame hive and commenced to build up an apiary. I will tell you how I succeeded. We commenced taking bees out of the rocks in the mountains. We took out 17, and ran our apiary up to 31 strong swarms. We had 13 new swarms come out, and sold $93.95 worth of wax and honey, besides what three families used. It seems strange to read in GLEANINGS about feeding sugar and packing them away for the winter. Here our bees are as busy as at any time of the year to-day. I tried to time a colony that was going in loaded with pollen, but I could not count fast enough. They would alight eight and ten at a time. The manzanita is in full bloom now, and will last about six weeks.

JOSEPH W. BELL.

Valle Vista, Cal., Jan. 19.

HOW I MANAGE MY HOME MARKET.

On page 55 is a letter from J. Handle, complaining of others supplying the home market after he had built it up. I have built up all the market for honey there is in Braceville, and have sold all I had to sell here, and could have sold more. I have had no trouble in the line he complains of. I furnish each dealer with a small show-case. The dealers here won't handle honey without a case, and they would not put other honey in my case. That helps to hold the trade here.

JOHN BURR.

Braceville, Ill.

WHEN TO SPRAY FRUIT-TREES.

There seems to be a threatening evil to our bees from spraying fruit-trees when they are in blossom. Could there not be something done to prevent it? I take the *Farm Journal*, and that advocates very strongly the spraying of trees. Would it not be well for some one to write to the editor of that paper, and tell him to inform the people when to spray them—when the blossoms are falling? The *Farm Journal* has a large circulation throughout the United States.

GEORGE BAKER.

Poplar Ridge, N. Y., Jan. 16.

FROM ONE TO FOUR IN 30 DAYS.

Last summer I had a swarm shipped to me the 19th of April. They swarmed the 31st of May, and again the 27th of June, and the young swarm swarmed the 30th of June, so I got three good young swarms from one.

W. F. NAYLOR.

Wrightstown, Minn., Dec. 22.

THE EFFECT OF IRON UTENSILS ON WAX.

I bought some 50 lbs. of dark-colored wax some years ago, supposing that I could clean it; but I found it permanently colored, being rendered in an iron kettle, and left to stand therein for weeks, so it is not salable.

Hayesville, O. H. BUTCHER.

Please tell me what causes the bees to cut up the comb.

J. P. H. WILSON.

Temple, Tex., Dec. 29.

[If your combs are spaced too close, the bees would be likely to gnaw away the comb. Space 1⅜ inches from center to center—not closer than 1¼ inch. Where robbing is allowed to get under a good headway, the combs of the robbed colony are liable to be torn into.]

MY REPORT FOR 1890.

I sold 318 queens, and spent $18.00 in advertising. My receipts were probably meager for the amount spent in advertising, but I have not a dissatisfied customer, nor a queen reported impurely mated. Many have wondered, and some have asked, "How are your books since you advertise 'to be paid for on arrival'?" I am glad to say I have found bee-keepers, as a rule, "gilt edge," and the best class with whom I have ever dealt; and the result is so satisfactory I shall advertise that way again another year.

THE HONEY CROP

the past season was short, and from 100 colonies I received 1200 lbs. (half comb, half extracted), which sold on an average at 15 cts. per lb. Late in the season, owing to frequent fall rains and mild weather, there was a profusion of bitter-weed from which the bees filled their hives for winter stores—something that has not occurred in several years. The honey is very unpalatable, but has a good body, and is about as dark as Spanish needle. The bees are wintering well, and on the 29th of December they were bringing pollen from elm. The discussion on closed-end frames has caused me to decide to use them with all new swarms another season. W. H. LAWS.

Lavaca, Ark., Jan. 16.

RIPENING OF HONEY NOT ALWAYS A PROOF AGAINST CANDYING.

In friend Beach's article, page 780, 1890, he says if the weather is warm and dry while honey is being gathered, and remains so until it is thoroughly ripened and sealed, in his opinion it will rarely ever candy. If friend B. had seen what I did last summer he would have talked different from that. The month of July, 1890, was very warm and dry here. Our bees at that time were working in the pine-forest and cotton-fields. The honey (or sugar, if you choose) would granulate just as fast as it was brought in. It was impossible to extract it, as it was just a thick mush. All the way it could be used was to cut it out in the comb, or use it in the building of new colonies. It is needless for me to say that this honey was as good and nice for the table as any honey ever raised. Friend B. also says we know when cotton honey is coming in, by the pollen on the bees' backs. If he will notice when bees are working on cotton he will see that very few bees go inside of the blossoms, or at least they do not in Mississippi. The honey is obtained from the outside at the base of the bloom. J. R. CLEVELAND.

Decatur, Miss., Jan. 27.

CLOSE SPACING AND FIXED FRAMES.

I am very sure that *less* than ⅜, instead of more, between the bottom-board and the bottom of the frames, is very important. If more, the bees must go up some other way; and, besides, there is much valuable time lost by the bees by too much space at the end of the frames; and for me I want every frame full clear to the bottom, so as not to allow any loafers. I know what it is to move hives in and out with frames loose or fixed, to say nothing of the trouble of taking off cases from loose frames. I shall use none but fixed ones of some sort, in the future. It is a wonder there are any in use except fixed. It's too much on the guessing-at-it plan.

Hallowell, Me., Jan. 15. E. P. CHURCHILL.

WIDTH AND THICKNESS OF TOP-BARS.

On page 888, 1890, Dr. C. C. Miller gives us a talk about the thickness of brood-frames and the building of burr-combs; and in Ernest's remarks following, he asks for information of others as to whether brace-combs are sometimes built through the honey-board, as Dr. Miller explains. I have had some experience with thick frames; and if you can profit by an A B C scholar's experience, here goes. When I first turned my attention to bees, about three years ago, I had no foot-power saw to make frames with, so I had to make them by hand. I made them the same dimensions as the Langstroth, described in the A B C, with the exception of the top-bar. I made this ⅞x⅞, so as to have a shoulder at the end to nail the end-bars to. Now, with these frames I have little or no trouble from burr-combs or brace-combs either; and I am inclined to think that a wider frame would be better. In fact, I think if the top-bars were wide enough, after being spaced they would be queen-excluding; and then we could, I think, dispense with the honey-board entirely. I am going to experiment with this problem the coming season, and will report. J. H. GOE.

Mossy Rock, Wash., Nov. 26.

OBJECTIONS TO THE T SUPER; WIDE FRAMES PREFERRED.

As I never see any thing in GLEANINGS or the *American Bee Journal* about wide frames, I should like to say a few words in regard to their use. Supers seem to be all the go. I have been using both wide frames and T supers, and I am completely disgusted with the latter. Bees very often build comb between the sections and the top-bars of the brood-frames, and this all has to be scraped off, and the sections are generally soiled or darkened on top by the bees passing over them. Again, you can not take 1, 2, 3, or 4 sections from a T super without taking the whole case off. Now, with wide frames there can not be any comb built on the under side of the sections, nor are they soiled in the least. You can take off sections where wide frames are used, just as you want them; you can take out a frame, fill with sections, and take 1, 2, 3, or 4, and just put empty ones in their places. I have sections in wide frames that have been in them for two years, and I am taking them out now, and they look as bright as they did when I put them in. Who can say this of T supers? W. S. DOUGLASS.

Lexington, Tex., Jan. 18.

[There is no need of having burr-combs or having the T super fastened to the brood-frames if you use a honey-board, or, better still, the right kind of brood-frames, with a bee-space of not more than ¼ inch above. Your greatest objection to the T super can be obviated if our own testimony and that of hundreds of reliable witnesses can be relied upon. But there is one thing which you have mentioned, and which is very true. In a poor season, or for any other cause that sections remain upon the hive for any length of time, the sections will discolor; that is, they will have a soiled, travel-stained, yellow appearance. In wide frames, or even in the section-holders, if an enameled cloth be laid flat (no bee-space) upon the section tops, the outsides of the sections will be clean and white, no matter how long on the hive.]

ONE WHO LIKES THE RUBBER GLOVES.

In answer to Miss Emma Wilson's inquiry in GLEANINGS for apron material, I would suggest oiled silk, if not too expensive. The rubber gloves are nice; and, every time they are taken off, they should be pulled off the hand so as to leave them wrong side out, so as to dry the moisture in them, or they will soon spoil, as they are air-tight. MRS. C. A. STEBBINS.

Churchland, Va., Feb. 5.

OUR HOMES.

What shall it profit a man, if he shall gain the whole world, and lose his own soul?—MARK 8:36.

Friend Root:—You may think it strange of me to write you such a letter as I have sat down to write, and may be you will think I am interfering with what does not concern me; but believe me, I have given it no little thought, and am going to do just exactly as I would wish to be done by under like circumstances. I am a Christian, though I am far from being a perfect one. I know what the power of temptation is, and it helps me to have charity for others who make wrong steps. I think the more popular any Christian becomes, and the more good he wants to do in the world, the more untiringly Satan will work to trip him; and so the more watchful and prayerful he must be.

I will tell you what I refer to. I am a member of the Southern California Bee-keepers' Association, and at our meeting Jan. 8, at Los Angeles, bids were sent in by the various supply-dealers to furnish the association with needed supplies. You will remember you sent a bid, and then added a postscript, saying that, if there were lower bids, let you know, as you could furnish supplies as low as any one.

Now, can you see where that placed you? In the first place, it looked very underhanded and dishonorable; then it looked very grasping, as though you would wish to sell all the supplies used in the United States, or perhaps in the world. A murmur passed through the assembly. Some of them, in speaking of it, said they were "glad to find you out." Others said they "almost knew your spouting on religion was merely for the dollars it would bring you." Now, I do not believe you thought twice before you wrote that postscript. I am very sorry, for I often think that we who are trying to further the cause of Christ are holding it back by inconsistent lives. See Romans 14:21. Yours sincerely,

Redlands, Cal., Feb. 16. H. P. LUTHER.

May the Lord bless you for your kind letter, friend Luther. By no manner of means do I think you are interfering, dear brother; on the contrary, nothing does me more good than plain outspoken words—that is, where they are spoken or written with the spirit that I am sure actuates you in the above. I do believe you are doing exactly as you would be done by, as you express it. Your thought is a grand one, where you speak of having charity for others *because* you yourself know what it is to be tempted. And this is one of the good things about trials and temptations—it keeps us from being overbearing, and judging others harshly. "Forgive us our debts as we forgive our debtors." Your next thought, too, is an important one. It is indeed true, I believe, that Satan *persecutes* and follows more *untiringly* any child of God who promises to become *popular*. When Finney was doing his great work through Ohio and York State, he was once overheard praying by himself out in the woods; and the burden of his prayer was that God might help him to bear *prosperity* in his spiritual work. And I want to thank you again for telling me so plainly and kindly just where you think I am at fault. If you will go back to that letter, however, which was read at the meeting of the association, you will find the expressions you mention were not the words of A. I. Root himself. As all the correspondence, however, that goes out of our establishment is supposed to be authorized by myself, I accept the responsibility, and the rebuke that comes with it. Let me say, however, in extenuation, that there are circumstances connected with this matter which I think your association failed to take into account. In the first place, we were asked to make a bid as early as the *first of January.* In fact, the letter referred to is dated Jan. 1. Now, at this early season, in this locality, we can not tell very well what we *can* do. We do not know what the winter will be in affording suitable weather to move logs. We do not know how many are going into the supply business before spring; neither can we tell definitely what the demand is going to be. Perhaps in our bid we should have suggested something like this, and added that we might be able to do better a little later on. I have looked up the letter you refer to, and the postscript, which reads as follows:

> "If our quotations on sections and some other items are not as low as you have received from some other party, we should like another opportunity for a bid. We think, taking it all around, we can furnish you goods that will please you as well as, or better, than any other."

Now, if it were only one individual who objected to the above, I should be inclined to accuse him of a lack of charity. If, however, it was the voice of an association, perhaps we had better conclude they were right; for I have great faith in the old saying, that "the voice of the people is the voice of God." Permit me to say here, that the writer of the above is our business manager, and my son-in-law; and to Mr. Calvert is due, perhaps more than to any other one person, the fact that our business has, within a few years, extended and enlarged so that our goods now go to almost every habitable part of the earth. Mr. Calvert's special forte seems to be in compassing the whole earth; and he has a gift that I have never seen equaled for keeping in hand, and under his eye, business transactions not only of great magnitude, but scattered here and there until an ordinary mind would become utterly confused and demoralized. Please, dear friend, remember that Mr. Calvert, like you and myself, is a follower of Christ Jesus, and an enthusiastic supporter of missionary work throughout the world, and one who gives so liberally of his earnings to these causes that I often feel like rebuking him. Now, let us remember that we all have our special individualities. Mr. Calvert does not write nor speak in that peculiar way your old friend A. I. Root does; but I am sure he *feels* just as kindly to his fellow-men as I do. Perhaps I may say, without any thought of boasting, that God in his mercy and love has seen fit to give your old friend a *peculiar* gift in talking to people, and in getting acquainted, and especially in *making* friends; and it often happens that those who have done business with me, and corresponded with me for years, notice the difference when the magnitude of our business obliges me to delegate to others the task of dictating correspondence. Both Ernest and John say, and with justice in their favor too, that it is impossible, with the present amount of business, to explain at length in the way I have been in the habit of doing with my friends. No other business house does it. In fact, when *any* business begins to assume large proportions, people are obliged to take for granted many things or to "read between the lines" as it were. As an illustration: When goods decline in value, every good business house should, as a matter of course, make the price lower to customers, and I believe this is generally done. When the recipient finds that the goods do not cost what he expected to pay, he does not demand a letter of explanation. He takes it for granted that there has been a decline in price, but he does not find fault, even if no explanation is made.* On the other hand, suppose goods advance. In this case I *do* think that every dealer should make at least *some* sort of brief explanation, even if it be a class of goods that is going up and down in value almost constantly. But yet a good many do not do this, relying upon their notice that certain goods are liable to advance without notice. At the present time we are having considerable jangle because alsike is $9.00 a bushel instead of the price printed in our circulars last fall. We write our customers, again and again, that we gave notice of the advance in our January GLEANINGS; but quite a number stubbornly insist that they got the price out of our catalogue—$7.50, and some say they will not pay any more. You may suggest that we should have written to them of the advance before filling the order. But suppose the proper season for sowing the seed is at hand, and the man wants it right off. Then delays become expensive. Now, if it were possible for me to write a pleasant letter, explaining with every such order when goods advance, I could almost always prevent hard feelings. But, dear friends, it is absolutely beyond my strength or power.

---

*A letter has just been placed before me, illustrating so well the above, and at the same time paying a just tribute to our friend Mr. Calvert, that I have thought best to give it here in a foot-note:

MR. ROOT:—Your letter of the 28th is received, in which you say you give me an extra credit of $1.65, because the goods had become so much cheaper, for which please accept thanks.

Every few days I come to the verge of overwork, and sometimes this overwork is in consequence of trying to pacify some offended customer in a matter of less than a dollar—sometimes, in fact, only a few cents. He will have it that we are greedy and grasping, and that "A. I. Root's religion is only a shrewd scheme to get hold of the dollars," as you express it. I have made all this explanation to let you see how impossible it is for me to dictate all these letters in regard to business.

Now in regard to the postscript I have given above. I presume that, if I had written that clause, I should have made it something like this:

"My good friends, at this date, Jan. 1, it is hard for us to tell exactly what we can do. We do not dare, at present, to give the close figures we may be able to give a little later when we see how our supply of basswood turns out. If our good friends at the convention do not insist on having exact figures right off now, we should be glad to hear from you a little later; and if you do not think it out of the way, we should like to have you tell us what bids you get, before you close the bargain with any one."

Well, the above is *in substance* just what Mr. Calvert wrote you, only it is told in my usual familiar way, instead of in a brief, business-like way as he puts it.

But, dear friend, my spirit moves me. I must say I am completely surprised at your honesty—so much so that I said to my wife, "Well, this man is surely honest enough. Certainly not one in a hundred would give a man the benefit of a lower price AFTER the goods had been sent and the bill made out." Of course, in the seven years I have been dealing with you I have always found you to be square and honest, but I did not expect it to go as far as that. JULIUS JOHANNSEN.

Port Clinton, O., March 2.

Perhaps you may wish to know what has brought forth such extravagant expressions. Well, it was simply something that our friend Mr. Calvert (the very man who wrote the letter to the association) wrote just as he does almost every day. An estimate had been given for some goods, the price agreed upon, order made, and the goods shipped. But a decline in prices (a week later) made it possible to make friend Johannsen's bill a little less; so Mr. Calvert, in a neighborly and Christian spirit, wrote as follows:

FRIEND J.:—As we are getting better prices on Planet Jr. implements, we credit you with an extra discount of 10 per cent on $16.65, the amount charged you for goods which went forward from Philadelphia on the 21st of February. Amount of credit, $1.65. A. I. ROOT.

Medina, O., Feb. 28.

Now, this is the way we are *trying* to do business, dear friends—not because it will prove to be a big *advertisement* to us, but because we love Christ Jesus, and try to live in the spirit of our opening text.

Yes, I know that, as our business increases, these Home Papers are going to be criticised and assailed. I feel that it is all the more because there is springing up all over our land a disposition to feel hostile toward those who handle capital, and who have the attendant power and influence that almost always accompany capital. Here in our own town a bitter spirit often comes up against me because I do not *employ* certain people to the exclusion of others. Of course, these friends do not look from my standpoint, and they do not know the full circumstances of the case. I can illustrate this by a little circumstance that happened only yesterday. On account of a lack of seasoned basswood we were obliged to suspend, for the time being, several hands. One of these came to me and said something like this:

"Mr. Root, will you think it impertinent if I ask you why you stop some of your older hands, and keep others who are no better workmen, and who have come later? Have I done any thing to merit your disapproval, or is there any way in which I can better serve you than I have been doing?"

I assured him that he had not offended me, and I had no complaint to make at all. But I told him the individual we were talking about was a stone-mason by trade, who, during a great part of the summer, when we were at work on our new building, refused to have his wages advanced. As you well know, stone-masons command a higher price than people of many occupations who have work all the year round. One day when I urged the matter, and told him he ought to accept more pay for the work he was doing, he replied something like this:

"Mr. Root, you put yourself out of the way to give me something to do at a season of the year, and at a time when I could find no work, and when I was needy. You have been giving me work every day in the year, whether it stormed or not; and now that you want something done right in *my line*, and I see a chance of doing you a favor, just as you did me, I am going to do it. You need not say any thing more about it. I shall not take any more pay. In fact, I rather enjoy showing you that I can remember a favor."

Now, friends, you see I had most excellent reasons for doing just as I did; and yet the outside world looking on, knew nothing of this; and even if I had the time, it was not my business to explain all my motives for action. In this conflict of capital and labor, I get glimpses of just this very state of affairs. My friends who are lawyers or bankers, or men who have money to let or factories to run, are criticised and called unjust. They are also accused of being open to bribes; and people say nothing can be done except by wire-pulling and "getting inside of the ring," etc. And yet, when the truth comes out they have reasons for their conduct much like the simple circumstance I have given above.

I am afraid, dear brother, that my California friends are disposed to be uncharitable when they say that Mr. Calvert's postscript "looked underhanded and dishonorable;" neither can I see that they were right in thinking it looked "grasping," and that we "wished to sell all the supplies used in the world." A little reflection, it seems to me, should show them that this is not true. Although we have been the pioneers, almost, in many things pertaining to bee culture, we have no patents on any thing. In fact, if any of you want to start an opposition business to our own, and should write and tell us so, you would get a prompt reply, to the effect that we would give you all the assistance in our power. You can come here to our establishment, and take the dimensions of every machine we use. You can bring your "Kodak," and take views of the machinery and appliances that we have been long years in studying up. At the Detroit convention a young friend came to me in a sort of bashful way, and told me he had been making Dovetailed hives to some extent. I assured him I was glad to know it, and looked at the samples of his work. He finally told me that he felt a little ashamed of having copied us in the way he had done, without even asking for the privilege. He then asked me how much *money* he should pay us so that he could go home with a clear conscience, and make Dovetailed hives out of pine-trees that grew on his own farm, for he already had a sawmill. I indulged in a good hearty laugh, and told him I was glad to know they had a man in Michigan who was enterprising enough to make bee-hives out of his own trees. When an opportunity offered, I held a sample of his work up to the eyes of the convention, and told them they could save expensive freights by sending their orders to our friend in question. Now, do you think it was any task for me, or that I found any selfishness to overcome in so doing? Why, bless your heart, no. My temptations do not lie in this direction at all. I have done this thing so many times (I was going to say all my life, but I had better say, since I became a *Christian*) that I have not a particle of fear of the result. I have seen the little text, "Give, and it shall be given unto you." verified so many times right along in this line that I feel as sure I shall not lose by it as I do that the sun will rise to-morrow. The enjoyment of helping somebody who is really honest and hard-working is worth a great deal more to me than the dollars and cents. I have my temptations, like yourself, to struggle with, and scarcely an hour of my life passes without a regular tussle in overcoming some sort of evil. But it is *not* at all in the line of wanting all the business in supplies for every apiary in the world. It is rather, that I want to be *helpful* to my *fellow-men*, and, therefore, I wish to respond with alacrity, and show myself wide awake whenever somebody comes to me with his wants. Do you know how many people there are in this world who fail in business just because of the *half-hearted* way in which they wait on customers? A grocer sits on a chair out on the sidewalk, waiting for customers. By the way, I always feel suspicious of the proprietor of *any* store who thinks he has nothing to do but to wait for trade. The grocer, like the farmer, should always know a *dozen* things that he can do profitably, no matter what the circumstances are. Well, suppose you go to one of these chaps who is waiting for trade to "turn up." You ask him whether he has any eight-penny nails. I have seen dealers who would say, "No, sir, I haven't any," and go right on talking *politics* with his *neighbor*, without another word to his *customer*. What should he do? I will tell you what *I* would have him do. If he really is sitting on a chair on the sidewalk, he should spring to his feet with alacrity, and say, "My dear sir, I am sorry to say that I am just out of *eight*-penny nails; but I have some nice sevens and tens. Just look at them. Perhaps you can make them answer. If the tens are too long, you may drive them a little slanting; and if you drive them first one way and then another, they will hold a great deal stronger than eights driven straight in."

Now, I think this latter is the right way to treat a customer. Of course, you should not hold on so as to detain him. If he says he rather thinks he will go somewhere else to get the eights, don't hinder him another minute. A man who wishes to sell goods should strive to be *accommodating* in the truest sense of the word. He should try to be *helpful* to his customer; and even though some people should say that he acts "grasping" and use such remarks, I do not believe he should alter his plan on that account. *Sometimes*, when I go somewhere to trade I find the clerks overdo the matter in *trying* to make sales. But this does not happen one time in a hundred, compared with the people who are so half-hearted and sleepy and dull in taking care of their business that they *can't* succeed. I have never found more than one or two clerks in my life who would wait on every customer as I would have them waited on. Our successful drummers, who command a salary of from two to three thousand dollars a year, give us a fair illustration of what is wanted. They will find out in a little while what a man wants, and they will make themselves really useful and helpful to him. They will give him hints, and tell him things of value in his business, worth many dollars to him; and they do it just as cheerfully and pleasantly, even if they do not succeed in making a trade at all. A man once came into our machine-shop. He looked over our work and our machinery, and finally showed one of the men how he could have the lathes arranged so as to keep two running instead of one, and finally demonstrated to us so clearly that we could save more than a dollar a day by having an extra lathe, that he made a sale of one worth $150. He was the proprietor of a machine-shop in a neighboring city, and he was obliged to wait here for a couple of hours for the train. Now, he did a stroke of business for himself in these two hours. He also gave us some valuable suggestions in our business that have been worth considerable money to us ever since. You see, friends, there is an extreme both ways in waiting on customers and in looking up trade; and is it not clear, too, that a man may seem greedy where he is only wide-awake, and full of energy and zeal to do with his might what his hands find to do? But inasmuch as the Bible admonishes us to beware of even the *appearance* of evil, we thank our good friend Luther for his timely caution, and promise to be careful in the future about even *seeming* to "want to gain the whole world."

SPECIAL DEPARTMENT FOR A. I. ROOT, AND HIS FRIENDS WHO LOVE TO RAISE CROPS.

FARMERS' INSTITUTES.

We had a farmers' institute in our town on the 4th and 5th inst. Among other things the silo question was discussed. One of Crawford County's progressive farmers stated that he could raise feed enough on one acre to keep a cow twelve months, in good condition. Teaching agriculture in the common schools was discussed at length. Secretary Woodward said, "Put yourself in as boss of your farm; value your services at one hundred dollars per month, and make the farm pay it." Your friend T. B. Terry was present, and delivered an excellent lecture on potato culture. All valued Mr. Terry's remarks highly. It made one feel as though he wanted to plant potatoes right away, after hearing him talk. The bee-industry was touched slightly, and some of our neighbors who have kept bees "nigh onto forty years," gave a few hints on the subject. By the way, friend Root, I think if we could have more such meetings as this it would be a source of health, wealth, and happiness. VERNE FREE.

Townville, Pa., Mar. 7.

TOBACCO AS THE BEST AND CHEAPEST REMEDY FOR BUGS AND INSECTS THAT VEX THE MARKET-GARDENER.

When visiting the greenhouses at the Experiment Farm in Columbus I asked friend Green how it was that they had no trouble with the green fly. He replied:

"Oh! we do have trouble—or, rather, we should have, if we did not keep them down with tobacco."

"But, friend G., will tobacco really do the business when they get well started, and get on the under side of lettuce-leaves, where the plants are thick and large?"

"Oh, yes! I think tobacco will manage the whole business, provided you use enough of it. Let me show you how we do it, and how quick it works."

He took a handful of tobacco dust, and found some radishes where the green fly had made something of a start. He sprinkled it on the leaves, and put on enough to mulch around the plants, and we kept on talking. In just a few minutes he told me to look. Sure enough, the green fly was over on its back in the dirt, and had "turned up its toes." I then began asking where he got it, and what it cost.

"Why, it does not cost any thing. It is the dust they sweep up from the floor at the tobacco-shops, and they give it to us for taking it out of their way."

Now, I had used this tobacco dust before; but mine cost me something like $6.00 a barrel, and we could not afford to use it as liberally as friend G. had been doing. In their reports in regard to the striped bug on melons and cucumbers, I remember they gave tobacco dust as the cheapest and simplest remedy. Sprinkle it on so as to make a mulching perhaps a quarter of an inch deep, right over the hill, so the plants must come up through it, and they will not be touched. If a very heavy rain, however, should wash it off and take the strength from the tobacco, give the vines another sprinkling. Now, where you can get this dust cheap, it certainly is the cheapest, quickest, and easiest remedy to apply that has ever been invented.

SOME QUERIES ABOUT RAISING CELERY.

Will liquid manure do the celery good? What time of the day is best to put it on? Could I not dig a trench, say one foot deep and four feet wide, and lay rails along the side of the pit to raise it just above the tops of the celery, and throw some old boards across, and some straw and some earth on top of it, leaving both ends of the pit open so I could open or shut, according to the weather? Could I not bind a dozen roots in a bunch and ship it on a car, laying it one on top of another, without jamming the celery or hurting the sale of it?

Unionville, Ont., Feb. 15. JOHN J. GRILLS.

[Friend G., the cheapest way to apply liquid manure to celery or to almost any thing else, is to scatter the manure on the surface of the ground around and among the plants; and then when it rains, the water will wash the liquid manure down around the roots of the plants better than anybody can put it on; and it saves all fussing with a barrel of manure, sprinkling-pot, and water. Your plan for wintering celery will be all right if you have a roof overhead that does not let the rain get through, and plenty of straw around the sides to keep the frost out. Most markets demand that celery be nicely trimmed, washed, and tied in neat bunches, and put up in clean, tight packing-boxes. If it is exposed to the air it very soon wilts, and in that case you can hardly give it away. You had better visit some practical man, and see just how he does it.]

CLOTH FOR HOT-BEDS AND COLD-FRAMES.

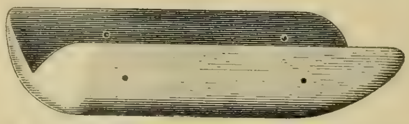
Will you please tell me how to prepare cloth to make it water-proof for hot-beds?

Willow Springs, Mo. J. N. NEWCOMB.

[Friend N., my experience is that I would not prepare it at all. I would rather have plain, strong cotton cloth than any with any preparation on it. The preparation may be a little better for the time being; but instead of preserving the cloth it makes it rot. I noticed that our friend who writes the tomato book speaks of only plain cloth without any preparation. If any of our readers have had experience to the contrary, we should be glad to hear from them. The great difficulty we have in using cloth, say in February or March, is from wind, snow, and rain. It raises the mischief with it, where glass would be undisturbed.]

A HOE-HANDLE ATTACHMENT.

Friend Root:—Haven't you wished a great many times, when you were tired, and perhaps thirsty, that your hoe-handle were not so dry and slippery as to necessitate expectorating so often on the hands? It has been the case with me, as well as of thousands. I often think there is a remedy for such complaints. Several years ago a simple device came to my mind, and I have often thought I would send it to you, and so I send it by mail to-day. Simply nail one on the hoe-handle near the end, the other about 18 inches from that, with ⅞ wire nails. Get them even, and both on the under side. They are first rate on a steel rake, and on all kinds of pronged hoes, and you can use such tools with mittens or gloves on when too cold; and the hoes, etc., won't be the wrong side up. I know from experience that one will not get nearly as weary as when he must grasp with all his might, besides spitting his whole life out, unless he is one of the spitting kind. I know it is a little early to talk hoes, but everybody ought to be happy once; and for so simple a thing it will call out happy thoughts. I am not boasting, but all should be improving and pressing onward. There is no patent on this, and I haven't got rich out of it, in dollars; but my feelings have been elevated by it very much. Please put them on and try them at something. You may see some way to improve them. I simply cut out a square corner, and think they are the right size. In digging potatoes with a pronged hoe, I tell you they are grand.



BLOCK OF WOOD TO BE NAILED TO YOUR HOE-HANDLE.

I have a wheel-cleaner for wheelbarrows, and I can not get along without one on hand-cultivators. You know a barrow-wheel is always rolling up a lot of soil, especially on clay land, such as you and I have. I will send you a sample later, if you wish. By the way, friend R., a large wheel on a cultivator is bad for working close to raspberries and blackberries. I think a 12-inch, as a whole, is the best. I speak unselfishly. E. P. CHURCHILL.

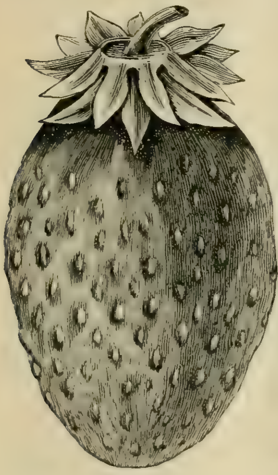
Hallowell, Me., Feb. 2.

[Friend C., with our modern implements, both for horses and for hand use, the old-fashioned hoe is getting to be a good deal discarded, and I think it ought to be. On our place we use rake-hoes a good deal instead. But this implement will perhaps be a help with them as well.

If we could always work our Medina soil at just the right time after a rain, we could dispense with very much of the hard work connected with keeping crops clean. Yes, we have had much trouble in having the wheel to our wheelbarrow clog up after a rain. especially where the load comes close to the wheel. as it ought to do; and we shall be very much obliged to you for a sample of your wheel-cleaner. By the way, friend C., if you have the machinery for making these things (and who else can do it better and cheaper?) you should make them and offer them at a low price by mail. It will be a great deal cheaper for most of us to buy them of some one who makes a business of making them, rather than to try to whittle them out ourselves. If you put them at a low figure we will give you a free notice of them.]

THE BELMONT STRAWBERRY.

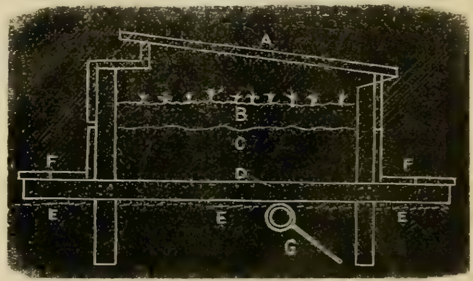
Two years ago a neighbor wanted to swap some choice strawberries, and among them were 50 Belmonts. I very soon noticed that this plant on our soil made better growth, and presented a handsomer and brighter foliage, than any other. I began searching the catalogues to see what they said about it; but I did not find very much in its praise, except from the introducer, several years ago. The experiment station said it did not fruit evenly. Part of a row would give a good crop, and another scarcely any. I judged from this that probably it wanted a very rich soil. But the plant was such an exceedingly fine grower, and so handsome in appearance, that I planted out two long rows at a venture. Well. it has not borne as much fruit, perhaps, as the four I have selected; but the berries we did get were so very handsome, and of such excellent flavor, that I was very much inclined to fall in love with the Belmont. Then its odd shape—the very sight of it is suggestive of "continued sweetness long drawn out," or of a great drop of nectar ready to fall if you don't catch it in your mouth. We are giving it another trial on a larger scale; and if they bear fruit even fairly, I think I shall put the Belmont among my chosen few. The beautiful cut was kindly loaned me by our good friend and veteran strawberry-grower, Mr. John Little. of Granton. Ontario.



THE BELMONT.

COLD-FRAMES AND HOT-BEDS.

Perhaps you would think it a little funny if all my inventing and speculating on greenhouses that can be made "outdoors" whenever desired, should finally come back to the old-fashioned cold-frame or hot-bed. A great many of the plans I figured out would work nicely, only they cost too much money; and then expensive machinery is always in the way when you do not need it. The present result of all my studying seems to be that the cheapest machinery in the present state of our knowledge, for moving sash, is two men—one at each end of the sash. While I dictate this, my eye rests lovingly on a hot-bed 150 feet long, just across the street. We have some beautiful light strong sash. 3 feet 4 inches wide. 6 feet long, and made of 1⅜ lumber. The 8x12 glass, instead of being lapped. have their ends butted together. and all the joints made tight with the putty-bulb and sand. I am not yet satisfied with a place to put the sash when it is not wanted over the plants. What we are doing just now—in fact, what we have just done this morning, is to pile up the sash five high, right on the bed. To do this, the men simply have to take two sash and lay them on the top of a third one; then put two sash from the other side on the same pile. This is very little work, and four-fifths of the bed is uncovered. The next time the sash are handled we will shift them so as to put the pile in a new place every time. When we want the plants to catch an April shower, as soon as the bed is thoroughly wet we shift the piles of sash.



CROSS-SECTION VIEW OF OUR NEW 150-FOOT HOT-BED.

EXPLANATION.—A is the sash; B, soil; C, manure; D. chestnut strip; E. surface of the ground; F. plank to walk on; G. 4-inch sewer-pipe, which should be shown under middle of bed.

To enable the workmen to work easily during wet muddy weather we have two planks for a walk. on each side of the bed. The north side is 8 inches higher than the south; and on an average the sash stand two feet from the ground. The planks for the sides are nailed to short cedar posts five feet apart; and the inside, next to the dirt, is covered with tarred paper to keep out frost. On the north side the cedar posts are sawed off square, and a 2x6 Norway plank nailed flat on the top of these posts. This piece covers 6 inches of the ground inside of the cold-frame, so the plants on the north side will have 6 inches for the roots to go over and under the six-inch piece. When handling the sash it is very convenient to be able to get the ends of your fingers under the sash to lift it up. To do this, each end rests on a strip of pine one each square. With this arrangement for getting under the ends, and the planks to walk on, two smart boys will uncover a 150-foot bed very quickly. The two walls are prevented from spreading by strips of chestnut, nailed from one cedar post to the opposite one. These strips, to be out of the way for spading, are about 18 or more inches below the surface of the bed; and as there is no other connection between the two sides, we can, if we choose, put a horse and cultivator right into the bed, when the sash are out of the way, so as to fine it up thoroughly, much cheaper than it can be done by hand. About 18 inches of manure is put in the bed, and from four to six inches of dirt on top. I am now ready to tell you of another feature of my new hobby.

USING EXHAUST STEAM TO WARM UP HOT-BEDS, GREENHOUSES, ETC.

For some years I have been feeling uneasy whenever I see steam puffing out into the open air from any kind of steam-mills, factories, etc. I have felt uneasy that this vast quantity of heat should not be utilized for warming buildings, or, in the spring and winter, for heating the ground and raising plants. Well, the engine that runs our printing-press and carries the dynamo for the electric lights is only about 150 feet from my new hot-bed. When the bed was made I laid a four-inch tile about a foot under ground, through its whole length, right in the center of the bed. Then with a two-inch iron pipe the exhaust steam from the aforesaid engine was sent into this four-inch drain-tile. I soon found the steam was heating the whole bed, with a large surplus, so I have given it another line of tile about 200 feet long. It has not yet gone to the end of this latter line; but during the last few weeks it has produced the most beautiful and luxuriant growth in rhubarb and strawberry-plants that I ever saw in my life.

Michel's Early, put out perhaps three weeks ago, have made such a growth that they are almost ready to send up blossoms for fruiting. This hot-bed was planned particularly with the end in view of getting our choice varieties of strawberries to put out runners as early as possible, in order that we may have young plants to send out, say in May or June. This will prevent the usual vacancy between plants grown last year and the present; that is, we want to be able to fill orders for plants during the very time when the strawberries are fruiting. For several years we have had orders for plants right during berry-picking. Of course, we can cut off the fruit-stalks and take up the plants; but this results in the loss of fruit, and the plant is not exactly what our customer ought to have, either. We shall see.

GLEANINGS IN BEE CULTURE

A JOURNAL DEVOTED TO BEES AND HONEY AND HOME INTERESTS

The way of the wicked is as darkness: they know not at what they stumble. But the path of the just is as the shining light, that shineth more and more unto the perfect day.—PROV. 4:19, 18.

THE *American Bee-Keeper* believes that the winter case will be in general use in the near future.

STERLING STRAWBERRY-PLANTS WANTED.

IF you have any for sale, say how many and how much per thousand.

THE APICULTURIST.

THERE is something in the *Apiculturist* that sparkles. It has lots of short, pithy items.

SHEET IRON VS. TIN.

Mr. ELWOOD says that sheet iron is cheaper and better than tin for hive-covers; and, besides, it holds the paint better.

THE TRADE-MARK.

SO far, bee-keepers seem to be against the trade-mark—at least, its establishment in the Bee-keepers' Union, although friend Heddon argues for it.

OUR TYPE-WRITERS.

FIVE Remington type-writers are kept almost constantly going in our office, and still we are behind in our work. We are contemplating putting in a new Hammond.

A KIND NOTICE FROM THE A. B. K.

HERE is a neat compliment from the *American Bee-keeper*, for which we extend thanks:

> Old reliable GLEANINGS keeps on in the even tenor of its way, growing better and better every month. Dr. Miller is the "bright particular star" in its firmament of contributors at present.

EXTRA MATTER.

IN the last issue we stated that we were going to give 8 extra pages; but we found we were obliged, at the last minute, to make it 12. But we do not suppose that any will complain. We give 16 pages extra this issue.

INDICATIONS

POINT to a remarkably big year for honey. Supply-dealers are springing up all over the country. A year ago the indications were that we should have a splendid season, but yet it was one of the poorest on record. We wonder whether it will be so again.

PROTECTION FOR SINGLE-WALLED HIVES.

THE above is the special topic for the *Review* for March 10. While there is not entire agreement, yet the general testimony seems to be in favor of a single-walled hive with some sort of removable winter-protecting case, instead of a hive having both walls permanently fixed.

TINKER'S PERFORATED ZINC.

DR. G. L. TINKER has just had built for him a new zinc-machine that turns out the zinc much more rapidly than his old one, and yet fully equal to the old samples that he has been sending out. He has just sent us some of his new zinc. It is simply perfect. That man Tinker is hard to beat on nice work.

WHY THE DOVETAILED HIVE IS SUPERIOR TO ANY OTHER FOR LASTING PURPOSES.

SAID our painter, who had just finished up a lot of Dovetailed hives, "Those joints will never gap to the weather, like halving and mitering, and hence they will outlast any other joint ever brought out. Keep the weather out of a joint, and it will never rot." There is a good deal of pith and point in this.

LADIES' DEPARTMENT.

MISS EMMA WILSON'S two articles have called forth so many more from the ladies, that we are going to renew the department in the next issue, as above. There seems to be a strong bond of sympathy among the sisters. May it continue! We shall be very glad to have the subject of bee-keeping for ladies brought up and discussed a little more.

DR. MASON AND HIS CANE.

WE learn from Mr. Detwiler that the "diamond in the rough," spoken of on page 171, last issue, is fast progressing to a nicely finished cane. He says that the stick is dressed and polished. The design will be in imitation of comb foundation, electrotyped in copper, and gold-plated. We hope Dr. Mason will bring the cane to every convention he attends.

FIXED FRAMES IN THE SOUTH.

IT would appear, from the article on page 224, that there are some localities where the closed-end or partly closed-end frame will not answer, on account of the large amount of propolis. We should like to know about how many of our friends in the South use them now, or have discarded them because of the propolis. We want the exact truth, let it come where it will.

THE BENTON CAGE SUCCESSFUL AGAIN.

We are just informed of the successful mailing of a select tested queen in a Benton cage, consigned to W. W. Somerford, San Miguel de Jaruco, Cuba. This makes the second time that the Benton cage has been successful in mailing queens to the West Indies.

DOVETAILED JOINT IN HIVES, 30 YEARS OLD.

While looking through the "Manual of Bee-keeping," by John Hunter, we ran across a hive with dovetailed corners. This, the author says, on page 88, was first described by Mr. Woodbury in the *Journal of Horticulture* in 1861. There has been some little discussion as to who first introduced the dovetailed joint on hives, that has since become so popular. This ought to put an end to the discussion.

THAT SHINY PAPER OF GLEANINGS.

Two or three have complained that our journal paper is too glossy to be read with ease. This same trouble applies to the *Century*, *Cosmopolitan*, *Scribner's*, *Harper's*, and other first-class standard magazines. To be able to print our half-tone work, and to bring the engravings out with the best effect, we have to use this fine paper. It will give no reflection to the eyes if you hold it at the right angle to the lamp. In the day time it will give no trouble.

HOW TO HANDLE FIXED FRAMES.

We expect to publish shortly some articles from Mr. Elwood and Mr. Hoffman, on how to manipulate fixed frames. These articles will be fully illustrated, and will explain many points which may not be clear. The great mass of bee-keepers do not yet understand *how* it is that fixed frames can be handled as rapidly as the loose frame. We have some beautiful photographs which illustrate each step of the *modus operandi*.

BOOMING THE BEE-BUSINESS.

Bee-journals have been accused many times of publishing only the *bright* side of bee-keeping, such as, for instance, reporting big yields, and letting the smaller yields go unpublished. The trouble is not so much with the bee-*journals* as it is with the bee-*keepers* themselves, who will not send in reports of poor yields. If they have a big yield they like to hand it in, because it looks well. A poor report may mean a poor bee-keeper, in the eyes of the public, they think.

THE CHIPS AND SHAVINGS DEPARTMENT OF THE APICULTURIST.

This is edited by E. L. Pratt, and the chips are crisp and full of hints and hits. Here is a couple of them:

> Father Root is acting as "ballast" to Gleanings. He thinks Ernest too progressive.
>
> If all the journals are going into the "cream" business, where are they going to get their milk to skim? Would a skim-milk bee-paper pay?

The first one is a sort of compliment to us both. Don't you see that it makes our journal broader?

HASTY IN CONVENTION.

Hasty is a valuable man in convention. He is brimful of that same vein that appears in his printed articles. He seemed to thoroughly enjoy the last meeting at Toledo, of the Ohio State Bee-keepers' Association. Toward the close of the session, Dr. Mason said, banteringly: "There, now, Hasty, don't you think that conventions are a good thing?" Hasty seemed to hesitate for a moment, and finally said, with a sly twinkle in his eye, "I have heretofore been opposed to conventions, but now I am half converted." There was a time when the senior editor of this journal was not a "convention man," but now he is altogether converted, and he goes every chance he gets.

SANDPAPERING DOVETAILED HIVES.

As the new Dovetailed hive is now sold by nearly all dealers, and by the carload, all over the country, a hint on putting together may come in place. After driving the dovetails home, nailing and squaring the hive, you can very greatly improve the appearance of the corners by the use of sandpaper where the ends of the tenons, as it were, come even with the surface. When thus treated, and coated with paint, the dovetails disappear, and the hive looks as if it were made of a solid block of wood.

SURPLUS COMMUNICATIONS.

Perhaps some of our correspondents are wondering why their articles do not appear. The fact is, we have a great stack of good articles; and although we use only about half of those sent in, there are others that we fear will have to be left out, though just as good, and in some cases better, than some we print. After they have lain a couple of months, many of them are out of date or behind the times; and to publish them later when we have space would be too much on the Rip Van Winkle style. We have enlarged our space to 16 pages for the present, but this does not let us out yet.

CIRCULAR SAWS; HOW TO FILE THEM AND KEEP THEM IN ORDER.

The best treatise I have ever seen on this subject is a book by Mr. Henry Disston, entitled, "Handbook for Lumbermen." As the book is also an advertisement of their saws and tools, I suppose they give them away—at least they sent us a hundred, and all we had to pay was the express charges. They ought to have been sent us by freight; but as they charged us nothing for the books, of course we could not well complain. Now, we will send them to any of our friends who will send us enough to pay postage and express charges mentioned, which would be about 8 cts. In my opinion this book is the best authority on this whole matter of saw-filing of any thing the world contains.

WASHINGTON ALMOST A MILLIONAIRE.

Our friends of the *Rural New-Yorker* are responsible for the following:

> After having been twice President, George Washington died, in 1799, worth $900,000, the richest man in the United States. Could the richest man in the United States be elected President to-day? Is the change in public opinion with regard to the holders of great wealth due to a change in the character of the millions or of the millionaires?

Had not the father of our country been so situated that he could advance money to the feeble and struggling colonies at just the time he did, can anybody tell what would have been our condition to-day? History says that Washington accepted no pay for his Revolutionary services of eight years, but simply allowed Congress to refund the money he had advanced to pay a starving and almost rebellious army. Of this rich man, Byron says he was

"The first, the last, the best,
The Cincinnatus of the West."

JOHN H. LARRABEE AND THE APICULTURAL EXPERIMENT STATION.

Some months ago Prof. Cook wrote to E. R. R., asking whom he thought would be a good man to take charge of the apicultural experiment station at Lansing. After thinking the matter over for some time, we finally recommended Mr. Larrabee as above. We stated that, if he could be obtained, he would be just the man. We heard nothing more about it until a few weeks later, when Mr. Larrabee himself stepped into the office of the Home of the Honey-bees. We asked him whence he came and whither he was going; and on being informed that he was going to Lansing we knew the sequel, and were pleased to know that our recommendation was accepted. Mr. Larrabee has been a successful bee-keeper in Vermont. He is educated, young, and enthusiastic. He combines all the qualities of an experimenter. So far Prof. Cook is greatly pleased with him.

DEATH OF MRS. P. L. VIALLON.

OUR space is so crowded that we are unable to give obituary notices generally; but we have just learned that P. L. Viallon, one of the representative bee-keepers of the South, a supply-dealer, an old subscriber and correspondent of GLEANINGS, has lost his wife. He writes:

> *Friend Root:*—On the 3d inst. I took my beloved wife to her last resting-place. She had an affection of the heart for several years, although in tolerable health; but about three months since, she took the prevailing influenza, the grippe, which brought on a complication, and involved the lungs, and on the 2d of March she breathed her last, in her 49th year. Out of eleven children she leaves three sons and three daughters, and your unfortunate friend, to mourn her loss. Only on the 7th of August last, we celebrated the 25th anniversary of our wedding, not suspecting the end so near for one of us
>
> Bayou Goula, La., March 5. P. L. VIALLON.

We extend to you our sincere sympathy. One of our old employes, Mr. J. C. Olin, who was also for a time in the employ of Mr. Viallon, says Mrs. V. was an earnest Christian and an estimable woman. It is pleasant, friend V., when such dear ones are taken away from earth, to feel that they have gone to a *better* land.

OUT-APIARIES: ADVANTAGES OF DIVIDING UP THE COLONIES INTO OUT-YARDS, INSTEAD OF CONCENTRATING THEM INTO TWO OR MORE LOCALITIES; A HINT FOR NEXT SEASON.

REPORTS at conventions, and testimonies through the bee-journals, have shown, over and over again, that, while one bee-yard will not give a pound of surplus, another, not more than three miles away, may yield a big crop. This is something that we can sometimes explain. In one section, the farmers have a big rage for peavine clover. Perhaps a few miles away some non-yielding-nectar crop has a similar rage. The result is, that the first locality will give a crop of honey while the second will not. It sometimes happens, too, that one yard is located near a swamp; and this source will usually give some honey, even during a dry season, while the other will give none at all. And, again, an apiary may be located on upland, among basswoods, and the latter will give a good deal more honey than the swamp yard. This shows the advantage in having out-yards. In some sections it may be advantageous to divide a yard having only 75 colonies. Mr. J. B. Hains, of Bedford, O., has something like 13 apiaries, and the number in each yard varies all the way from a dozen to fifty. His locality is such that no one yard can have profitably more than fifty colonies; and it pays him, therefore, to scatter his bees into small yards around the adjoining country. It is a significant fact, that occasional yards will not support much over a dozen colonies with profit. While there are those that will support 100, they are rather rare east of the Mississippi. The thing for us is to determine just how many a locality is good for; and then, when the colonies increase beyond the average right number, put them in another location.

SILVER-PLATING OUTFITS, ETC.; LOOK OUT FOR THEM.

So many inquiries are coming in regard to outfits for silver-plating for a few dollars, that are advertised (I am sorry to say) in a good many good papers, I feel called upon to make a protest. Good, durable silver-plating can no more be done outside of a plating-factory than one can manufacture knives, forks, and spoons at a profit outside of a factory. The very plan of advertising should at once suggest to every thinking mind that it is a swindle, reading exactly as if the *editor* took pains to tell of or to encourage something commendable; whereas the whole thing is a *paid advertisement*. No girl, no widow-woman, nor anybody else, ever did any thing of the sort; and the periodical that lends its influence and good name toward fostering and encouraging any thing of the sort will surely repent it. The man who sells his good name and influence in community for a few cents or a few dollars, will, in a very short time, find he has neither good name nor influence.

Here is a couple of them, taken from a county paper. The heading, you notice, is pretty sure to attract everybody's attention by its peculiarity:

> A GIRL WORTH HAVING.
>
> After reading Mr. Gray's experience in the plating business, I sent $3 to the *Lake Electric Co., Englewood, Ill.*, and cleared $21 in a week. Isn't this pretty good for a girl? There is tableware and jewelry to plate at every house; then why should any person be poor or out of employment with such an opportunity at hand? A SUBSCRIBER.

You will notice that the above is signed, "A Subscriber," giving people to understand that a subscriber to the above paper sends in this report, which is an absolute falsehood from beginning to end; and the editor who accepts such an advertisement and puts it in his reading-columns is a party to a fraud. In another place in the same paper is another, which reads as follows:

> MONEY FOR EVERYBODY.
>
> Mrs. Wells asks, "Is it a fact that a person can make $30 to $40 a week in the business?" Yes, I make from $5 to $7 a day, plating and selling plated ware. The Lake Electric Co., Englewood, Ill., will give you full instructions. In this business there is money for everybody. A READER.

Just for the fun o it we turned to Dun and Bradstreet, but there is no such concern at Englewood, Ill., at all. Very likely there is somebody there to take the money out of the post-office, and possibly they send some sort of apparatus. Perhaps some of our readers can tell us more about it.

THE WORLD'S COLUMBIAN FAIR.

THE following is an editorial which we clip from the *American Bee Journal*. As it contains just the information that many State bee-keepers' associations want, we are glad to give it entire:

> The Illinois State Bee-Keepers' Association decided to ask the Legislature to appropriate $5000 for the collection and maintainance of a suitable exhibit of bees, honey, wax, and apiarian appliances at the World's Columbian Fair. The committee to form the bill and present its claims are:
>
> Thomas G. Newman, Chicago.
> Col. Charles F. Mills, Springfield.
> Hon. J. M. Hambaugh, Spring.
> Hon. John S. Lyman, Farmingdale.
> C. P. Dadant, Hamilton.

A. N. Draper, Upper Alton.
S. N. Black, Clayton.

All other States should take similar action at once, so as to secure the appropriations in good time to command magnificent exhibits.

For the benefit of committees in different States, who will have to present the matter to the Legislatures and ask for appropriations, we will here reply to a question which has been propounded to us and to others a score of times. That question is—

WHAT IS THE MONEY NEEDED FOR?

The answer is easy. It is needed to procure, transport, organize, and take good care of exhibits, and may be particularized thus:

1. To pay a competent person for time and diligent work for a year or more, to procure, arrange, and superintend an exhibit which shall be a credit to the State.

2. He will need many assistants during the entire time of holding the Columbian Fair, to care for, and protect from damage or waste, the many articles exhibited, as well as to keep them clean and in proper condition for thorough examination by the millions of visitors. These must be efficient persons, and will have to be suitably paid.

3. Products of the apiary, machinery, and appliances, will have to be transported to the fair-grounds, and this will entail considerable expense.

4. We do not desire a separate building for the industry of bee-keeping, but it will it will be necessary to *fit up a large space* in one of the principal buildings devoted to agriculture, horticulture, or floriculture. To make it convenient, and have it attractively decorated, will cost money; but it will be well spent, nevertheless; for the general verdict at all fairs is, that the "Bee and Honey Department" is the most attractive thing on the grounds.

5. At the close of the World's Fair all the goods exhibited must be carefully packed and returned to the owners. This item of expense for labor, material, drayage, and railway transportation, will be very large, on account of the care required in handling and packing, so as not to destroy the values. Honey in the comb (in all forms and shapes imaginable) is delicate and fragile; and the utmost care will be required to prevent its being damaged or ruined entirely.

6. And last, but not least, cash prizes, medals, and diplomas, will of necessity be required to bring out an exhibit which will honor the State. This item must necessarily be a large one, for upon it will depend the success of the entire undertaking.

These are a few of the things that will require money, and for which a liberal appropriation is desired from the public treasury.

"THE REASON WHY."

On page 214 the writer of the above article makes this remark: "Because they are supply-dealers, and because it was to their interest to do so." Now, it has lately been getting to be quite fashionable to insist that large enterprises, either in publishing a journal or dealing in supplies, are built up by furthering selfish interests. No sadder blunder was ever made. The publisher or supply-dealer who does every thing for self-interest, never builds up a business. Honesty *is* the best policy; and candid, honest truth, is a thousand times more *profitable* than any sort of selfish, underhanded trickery. We urge beginners to start out with the standard frame, just exactly as we would urge a man who wanted to go somewhere, to drive in the road, when he was meditating letting down fences and going crosslots with his horse and buggy. We who have built up a business, or who have control of a successful bee-journal, are laboring for the good of our patrons, especially for the younger ones who are just starting. It is our business to save them from sad mistakes and blunders; and the insinuations that are constantly being thrown out, that success in business comes only to those who are sharp, tricky, dishonest, and selfish, and who are only after the almighty dollar, emanate from the evil one himself; and it will not only be the ruin of our people financially, if persisted in, but it will be the ruin of us as a people, *body and soul.* Hold fast to the little text, "thinketh no evil;" and for mercy's sake have charity enough to believe that your neighbor is at least *almost* as good a man as *yourself.*

FLORIDA AND ORANGE BLOSSOMS.

A FEW moments ago a beautiful bouquet of orange-blossoms, redolent of perfume, cam through the mails, with the following letter:

Mr. Root:—Please send me an extra copy of GLEANINGS for March 1. I think I like GLEANINGS better every copy I read. I read it through from one end to the other, and then look over the best things again. I took the first honey of the season on the 5th. It was from orange, peach, and plum blossoms. I send you some orange-blossoms by this mail.
SIDNEY SMITH.

Lake Como, Fla., March 10.

The flowers are so handsome, and the perfume so exquisite, that some of our office girls are thinking of going to Florida when they are ready to get married—that is, if the groom can scrape up the stamps for such a "wedding flight." I do not mean that they *said* so, but I judged by their smiles and pleasant looks that they were *thinking* of something of the kind as they passed the bouquet from one to another.

THE PRESENT PRICE OF ALSIKE.

Perhaps no one thing occasions more jangling and hard feelings than the changes in the prices of alsike clover—especially the rise that almost always comes about sowing time. Illustrative of this we give below a copy of a letter just at hand, from one of the large grass and clover-seed dealers in Cleveland:

A. I. Root, Medina, O.: Dear Sir:—Your favor of the 10th inst. is received. We inclose small samples of alsike, which we mark and quote f. o. b., subject to prompt acceptance and unsold, as follows:

"Frens," 4 bags, per bushel, $9.50.
"Lawson," No. 1, 3 bags, per bushel, $9.75.

Hoping to have your order, which will command prompt attention, we remain

Very truly, etc.,
H. C. BURT & SON,
Dealers in Wool and Grass Seeds.

Cleveland, March 11.

Now, friends, see where you would have been had you raised a big crop of alsike and kept it till the present time. We have not paid the above price, because it is considerably more than we have been selling at retail, and we do not propose to pay it unless we are obliged to. All we can promise is this—that, if you send us your orders, we will do the very best we can. If we are absolutely *obliged* to pay the above figures, of course we can not retail it for less than from $11 to $12 a bushel.

THE NEW WATER CURE, ETC.

ONE thousand copies of the above little pamphlet were given away in about a week. We are now printing a larger edition of 5000. Many of our friends who sent for ten or a dozen disposed of them so quickly that they have ordered another lot. All right. We believe we can print and mail as many as can be given away where they will do good. Several cases have already been reported where they have have gone into towns where agents were canvassing, at $4 for each secret; but ours soon wound up the $4 business. It seems to me that every good man and woman should be doing as much as possible to discourage or stop this system of defrauding people of their hard earnings, by false representation and false pretense.

KNOWN AND PUBLISHED IN GERMANY, OVER 40 YEARS AGO.

Our proof-reader has translated the following from a clipping taken from a German paper, the name of which we do not know:

Dr. Hall's medical pamphlet has made use of not a few of our western exchanges since the beginning of the year. Dr. Hall makes a good use of secrecy in the application of his highly recommended remedy; but when he is pushed as to its discovery it becomes evident that he is not well posted in medical lore; for there appeared a little book in Reutlingen, more than forty years ago, in which we saw all that Dr. Hall puts forth with so much secrecy. The *Germania*, of Milwaukee, took up at first a column of his recommendations; but finding afterward that there was nothing original about it, it gave the whole thing away to its readers. It contains only about 20 pages, written with great verbiage, and is sold to people for $4.00 by Dr. Hall and his agents.

Now, friends, there is a moral in all this. It transpires, as you see, that the whole of Dr. Hall's discovery was not only in print at the very time in our own country, but in other countries also; and with the multitude of books and periodicals now extant, as well as the multitude of thinking people and earnest students, not only in medicine but in all other departments of science and art, shall we not be a little slow in deciding that any one man has the right to monopolize and make capital out of any thing that comes up, that seems, for the time, to be new?

SPECIAL NOTICES.

ALSIKE CLOVER SEED WANTED.

If any of our readers have any choice alsike seed for sale they will do us a favor by mailing us a small sample, telling what they have and what they will take for it. The wholesale price still continues quite firm, and our stock is almost exhausted.

TOBACCO DUST FOR KILLING BUGS AND INSECTS.

As some of the friends may wish to try some of the tobacco dust spoken of on another page, we will say that we can furnish it as follows: 1 lb., by mail, 25 cts.; 5 lbs., by express or freight, 3 cts. per lb.; 10 lbs., 2½ cts. per lb.; 25 lbs., 2 cts. per lb.; 100 lbs., $1.75.

ADVANCE IN ALSIKE CLOVER SEED.

We are compelled to advance the retail price of alsike to the following, and may without notice have to advance still more, but will always give as good a price as it is possible to do. Bushel, $10.00; ½ bushel, $5.20; peck, $2.75; lb., 22 cts. No change is made from the prices quoted in last issue, on white and alfalfa clovers.

RUBBER TUBING, ETC.

So many of the friends have complained that they do not find the soft-rubber tubing I described in our last issue at their drugstores, I have taken pains to purchase a quantity that we can send by mail at the rate of five cts. per foot. We can also furnish the hard-rubber terminal tube at 10 cts. each. The above prices will include postage.

SMOKER FUEL AT 75 CTS. A BARREL.

This is a kind of sawdust and excelsior mixed, that comes from making bee-feeders and other work of this class, that is the best smoker fuel of any thing *we* have ever used, and we have tried almost every thing. We will dispose of what we have on hand, for 75 cts. a barrel, barrel included. It can go by freight. When you are ordering other goods you can easily have a barrel of this included.

OUR SEED AND PLANT CATALOGUE FOR 1891.

This is just out, and on many things we have been enabled to make the prices even lower than they were in our January number. Very few things have advanced much, with the exception of alsike clover. In our locality there is at present no opportunity to get plants outdoors, on account of the continued wetness. In fact, we have had more winter since the first of March than during all the winter months.

FOR SALE.

Thoroughbred Cheshire Pigs, Plymouth Rock and Light Brahma Eggs, Light Brahma Cockerels, and Unfermented Niagara Grape-juice. Write for prices. **C. J. BALDRIDGE,**
6d **Kendaia, Seneca Co., N. Y.**

Please mention this paper.

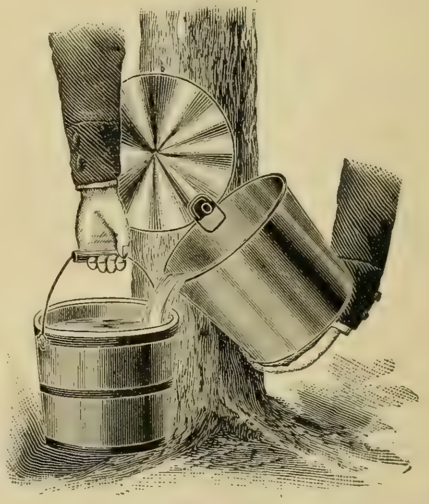
A Four-Color Label for Only 75 Cts. Per Thousand.

Just think of it! we can furnish you a very neat *four-color* label, with your name and address, with the choice of having either "comb" or "extracted" before the word "honey," for only 75 cts per thousand; 50 cts. per 500, or 30 cts. for 250, postpaid. The size of the label is 2⅜x1 inch—just right to go round the neck of a bottle, to put on a section, or to adorn the front of a honey-tumbler. Send for our special label catalogue for samples of this and many other pretty designs in label work.

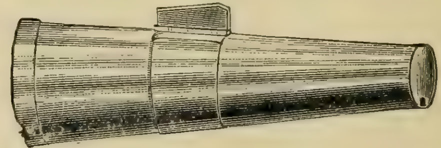
A. I. ROOT, Medina, O.

Maple Sugar Supplies

Maple-sugar-making time is at hand, and some are inquiring the price of supplies. First, you should supply yourself with that excellent book by Prof. Cook, "Maple Sugar and the Sugar-Bush;" price 35 cents; by mail, 38c. By studying this you may save many times the price of it. Notwithstanding the advance in the cost of tin, we are able to offer you sap-buckets and spiles and cans at last year's prices, as below:



Above cut shows a bucket hung on wire loop, with hinged tin cover, and manner of emptying.



IMPROVED RECORD SAP-SPOUT.

Record sap-spouts, $1.00 per 100; $8.00 per 1000.
10-qt. buckets, IC tin, $15.00 per 100; IX tin, $17.00.
12-qt. buckets, IC tin, $16.00 per 100; IX tin, $18.00.

Patent hinged covers, $6.00 per 100. Reversible wood covers, $4.50 per 100. Wire loops for wood pails, 30c per 100; for tin pails, 25c per 100. 1-gal. square cans, 50 or 100 in a crate, $12.00 per 100. Boxed 10 in a box, for re-shipment when filled, $1.50 per box; $14.00 for 10 boxes.

A. I. ROOT, MEDINA, OHIO.

ADVANCED BEE-CULTURE;

Its Methods and Management.

I am now engaged in writing and printing a book that is to bear the above title. It is to take the place of my other book, *The Production of Comb Honey*, which will not be re-published. Although the new book will contain at least five or six times as much matter as *The Production of Comb Honey*, yet the price will be only 50 cts. The book is already partly printed, and will probably be out some time in April or May. If any of the friends would like to "help me along" in meeting the expenses of getting out the book, they can do so by sending their orders in advance. Such orders will be most thankfully received, and filled the *very day* the book is out. I will send the REVIEW one year and the book for $1.25. The REVIEW will be sent on receipt of order (I have plenty of back numbers to send it from the beginning of the year), and the book as soon as it is out. Stamps taken, either U. S. or Canadian. Samples of REVIEW sent free. 10tfdb

BUCKWHEAT.

MARTIN'S PROLIFIC.

This buckwheat under favorable conditions will yield 70 bushels per acre, as it is an enormous yielder—stands up well and endures drouth remarkably well. Last season it yielded double the quantity per acre sown, under the same or rather worse conditions than my Japanese, 100 rods distant, and did not blast one-half as bad. I think it will supersede the Japanese when better known. Price $1.50 per bushel, 85c per half bushel, bags included. $1.25 per bu. for 5 to 10 bushels. Remit by P. O. order, bank draft or registered letter to the originator, 7-10db

WM. MARTIN, CASS CITY, TUSCOLA CO., MICH.

Please mention this paper.

GOLDEN ITALIANS.

AND THE BEE-KEEPERS' REVIEW.

I have purchased the queen that, together with her bees, took **first premium** last fall at the Detroit Exposition. They are the Five-banded Golden Italians. The **handsomest** and **gentlest** bees, and the **yellowest** drones I have ever seen. They are not inclined to rob, and it is claimed they work on red clover. After June 1st I shall offer the daughters of this queen for $1.00 each, or 6 for $5.00. I have a number of tested queens, reared last season by H. Alley from his "one-hundred-dollar queen," that I will sell for $2.00 each. In order to secure a few orders early, to all persons who send me, before **May 1st,** $1.75, I will send one five-banded Golden Queen, and the **BEE-KEEPERS' REVIEW** one year; for $2.75 one of the tested Alley queens and the **REVIEW** one year. The **REVIEW** is published monthly by W. Z. Hutchinson, at $1.00 a year. The **REVIEW** will be sent on **receipt of order.** Untested queens will be sent after June 1st; tested queens the last of May. All orders will be filled in rotation. Make money orders payable at **Flint, Mich.** Address

Honey Column.

CITY MARKETS.

New York.—*Honey.*—Market is entirely bare, with little or no demand, except for some 2-lb. fancy white, which would readily be taken. California extracted honey in fair demand at 6¾@7; Florida, 7½@8. *Beeswax.*—Stocks and supply very small. Prices gradually growing better. We quote, for good yellow, 27@28. **F. G. Strohmeyer & Co.,**
Mar. 19. New York.

Cincinnati.—*Honey.*—There is a good demand for extracted honey at 6@8c a lb. on arrival. Demand for comb honey is fair at 15@17c a lb. for choice white, in a jobbing way. Demand is good for *beeswax* at 24@28c a lb. for good to choice yellow on arrival.
Cincinnati, Mar. 18. **Chas. F. Muth & Son.**

Albany.—*Honey.*—Have received one consignment of comb honey in pound sections since last issue, and sold the clover at 16c and the buckwheat at 13c. We are out of buckwheat in pound sections. Dark extracted honey is moving off lively at 7@8c. Light sells slow at 9@1 c.
Mar. 21. **Chas. McCulloch & Co.**

Detroit.—*Honey.*—Comb honey is selling slowly at 14@15 cents. Extracted, 7@8c. *Beeswax* firm at 28@29c.
Bell Branch, Mich., Mar. 20. **M. H. Hunt.**

Kansas City.—*Honey.*—Demand continues steady for 1-lb. comb. Stocks very light, receipts light. We quote 1-lb. comb, white, 16@18c; dark, 12@13c; 2-lb. California comb, 14@15c. Extracted, 6@7c. *Beeswax*, 22@25. **Clemens, Mason & Co.**
March 23.

San Francisco.—*Honey.* — Extracted honey, 6c; Comb, 1-lb., 12@14½c; 2-lb., 11@12c. *Beeswax.*—No supplies. **Schacht, Lemcke & Steiner,**
Mar. 18. San Francisco, Cal.

For Sale.—"Choice orange-blossom" extracted honey in 60-lb. tin cans, or kegs holding 14 to 15 gallons. Price $1.25 per gallon, f. o. b. cars here.
Arthur F. Brown,
6 9db Huntington, Putnam Co., Fla.

For Sale.—1200 lbs. extracted white-clover honey in barrels or 60-lb. cans, as desired.

Special Notices.

GRAPEVINES FOR SHADING HIVES.

By some misunderstanding, our ordinary grapevine advertisement was left out of our regular catalogue, and also out of the seed catalogue. We have a beautiful stock of two-year old Concord grapevines, ready to ship. Price 10 cts. each; 85 cts. for 10, or $7.00 per 100. If wanted by mail, add 3 cts. each extra.

VEGETABLE-PLANTS FOR THE FIRST OF APRIL.

Asparagus-plants. We have a nice lot of fine ones, but they are only one year old. Price 10 cts. for 10; 75 cts. per 100; 1000, $6.00.

Cabbage-plants. We have only the Select Early Jersey Wakefield. Price 5 cts. for 10; 40 cts. per 100; $3.00 per 1000.

Cold-frame plants, none to spare.

Snowball cauliflower, same as asparagus.

Lettuce-plants. We have Grand Rapids and Henderson's New York, at the same prices as cabbage-plants.

Celery-plants. White Plume, Self-blanching, ready to ship. Same prices as cabbage-plants.

If wanted by mail, add 5c for 10, or 25c per 100, on all above plants.

Strawberry-plants. We are shipping daily, as per editorial or page 187, March 1.

ITALIAN BEES FOR SALE.

I will sell pure Italian bees in good L. portico hives at $5.50, or two for $10.00. Also pink and white sweet peas at 13 cts. per oz., or 75 cts. for 2 oz. 7d
C. G. Fenn, Washington, Conn.

NEBRASKA

For Nuclei Colonies and Italian Queens. Circular and price list now ready. 7tfdb
J. M. YOUNG.
Box 874. **Plattsburg, Neb.**

1891 Early Italian queens from bees bred for business. Each $1.00; six $4.50. Order now, pay when queen arrives.
7tfdb W. H. Laws, Lavaca, Ark.

DON'T FORGET

That I am now booking orders for those beautiful ALBINO QUEENS, and the well-known Italians. Send in your order and pay when queens are ready to ship. **A. L. KILDOW, Sheffield, Ill.**

GLEANINGS IN BEE CULTURE

A JOURNAL DEVOTED TO BEES AND HONEY AND HOME INTERESTS.

Published by A. I. Root, Medina, O.

Vol. XIX. APRIL 1, 1891. No. 7.

STRAY STRAWS

FROM DR. C. C. MILLER.

MARCH 14, 1° below zero!

FEED, FEED, if the bees need.

THE FIRST TWO weeks of March were the severest of the winter.

SEPARATORS, according to replies in *C. B. J.*, are not so popular in Canada as on this side.

TEN CENTS' WORTH of honey contains more nutriment than 50 cents' worth of fat pork, says Allen Pringle in *C. B. J.*

THE bammy breeze of spring
Is now upon the wing,
When bees will sting
'Most any thing.

"THE BEE-KEEPERS' UNION," says Jas. Heddon in *A. B. K.*, "will soon take out a patent in the shape of a trade-mark." I believe in patents, but not in that one.

AND NOW E. R. ROOT has gone and written a piece which Hutchinson has printed in the *Review*. If that sort of thing isn't stopped, the rival editors will get to be friends yet.

A HUNGRY QUEEN, I am somewhat inclined to believe, is more easily introduced. She's so much engaged trying to get something to eat that she doesn't go around raising a row.

HEDDON THINKS (*A. B. J.*) that, if the trade-mark problem is abandoned, there is "nothing better than to keep still," and let adulterators have their own way. James, you're off.

DOOLITTLE suggests that the reason I did not succeed with his cell-cups was that I did not make the cups as deep as directed. I think it quite possible that he is right, and I'll try again.

DOOLITTLE says, in *A. B. K.*, "There is no time in the whole year that it pays as well to put a little money in feed for bees, where they need it, as it does at this time." Doolittle's head is level.

CONTRACTION. I was somewhat surprised to see the editor of the *Review* say, "With an eight-frame hive I have seldom found it advisable to contract the brood-nest of an established colony." But he adds, "I *would* contract the brood-nest of a newly hived swarm."

AND NOW No. Two (*C. B. J.*) wants to know about "closed frame friends." Out west is a family by the name of Frame, familiarly called the Frame friends. When they get too much tangle-foot, and are shut up in the calaboose, they are then called "closed Frame friends."

THAT DESCRIPTION of the cut on page 174 pretty nearly beat me. Finally I made it out by putting B for D, making it read, "B is a hollow point, etc." But it isn't up to A. I.'s usual clearness.

REV. W. F. CLARKE continues to quote me as authority for the statement that he is long-winded, although I've said I didn't say it. If he keeps it up much longer, I may begin to *think* what I haven't said.

THE ILLINOIS STATE BEE-KEEPERS' ASSOCIATION has been incorporated. The first meeting was held at Springfield. The State Legislature is to be asked for $5000 to help the bee-keepers' show at the World's Fair.

HUTCHINSON says he, Dr. Mason, and others, always read the editorials first. That's no way—at least not in GLEANINGS. Always begin at the first page. If you begin at the editorials, you might forget to read the first page.

MACPHERSON, of the *C. B. J.*, has been laid up with concussion of the brain from a fall on the ice. Hope not for long. No Mac and no "pollen-grains" in *C. B. J.* makes a bad hole. "Observer" and "No. Two" liven up the pages of the *C. B. J.* no little.

"BOTHER THE SALT!" That's what you say when it's all packed together and won't shake out of the salt-cellar at the table. Let me tell you how to fix it. Put about a teaspoonful of corn starch in a teacup of salt, and mix. That's the way it is on our table, and it always yields.

KEEP TOOLS BRIGHT. I once saw a seedsman care for his hoe after using it. He washed it off clean in a pail of water, and then, without drying it off in the least, he stuck it in a barrel of wood ashes. "There," said he, "no matter when I want to use that hoe again, I'll find it dry and bright."

SOMETHING will have to be done pretty soon about the editorials in GLEANINGS. They're getting to occupy altogether too much room, and are covering so much ground in an interesting manner, that in a little while I'll have nothing to manufacture "Straws" from. Something will have to be done.

L. D. STILSON, of the *Nebraska Bee-keeper*, had a colony which worked on red clover when others did not, and wants to know if any one else has had a like experience. He forgets about the red-clover queens of Medina and elsewhere. One year I had at least two colonies storing white honey when all the rest were storing buckwheat.

E. L. PRATT, in *Api.*, thinks I'm off in recommending full sheets of foundation in all cases—thinks I'm "old enough to know better than to hive new swarms upon all full sheets of foundation." He's rather got me there, for I really don't know much about new swarms—don't hive one a year. Still, if I did hive one, and had to use full sheets or empty frames, I believe I'd be so afraid of drone comb that I would use full sheets (if I thought brother Pratt wouldn't find it out).

My thanks are due Mr. S. Corneil for calling my attention to an error of mine. I said Cheshire denies that contaminated honey may be a cause of propagation of foul brood (p. 156). I was wrong. He says he has never, by the most careful search in the worst cases, found the bacilli in the honey, and has discovered that it is impossible for bacilli to multiply in honey; but he says, further on, that they "must occur in honey as an occasional contamination," and, still further, says, "My strong opinion is, that, commonly, neither honey nor pollen carries the disease, but that the feet and antennæ of the bees usually do."

GENERAL CORRESPONDENCE.

PREVENTION OF SWARMING.

THE EFFECT OF LARGE BROOD-CHAMBERS, EMPTY COMBS, AND THE ARTIFICIAL REARING OF QUEENS, CONSIDERED.

On page 168, Mar. 1, in answer to C. W. Dayton, Ernest says: "An unlimited capacity is quite apt to discourage, if not to prevent entirely, all swarming. Neither Mr. E. France nor the Dadants, who work on this latter principle, have swarming to any extent, and they do get the honey, you know." Now, we may admit at the outset that contraction tends to heighten, and expansion to lessen, the swarming instinct. Also, the facts concerning the Messrs. Dadants and France are no doubt true. But in drawing your conclusion I think you assume too much. Are you sure there is no other immediate cause to produce the effect? I think there are two entities that conspire to produce non-swarming, so far, at least, as the Dadants are concerned.

WHY THE DADANT BEES DON'T SWARM; NOT LARGE HIVES, BUT RACE OF BEES.

One is, that they have developed a rather non-swarming bee. The other is a secret that I learned from Mr. J. M. Hambaugh, whom I met for the first time in Springfield last December. We were discussing large hives, and working for extracted honey, in connection with the prevention of swarming. I referred to the discussion of the causes of swarming, conducted in Gleanings in 1889, by Dr. Miller and others. I wish you would look up the papers on pp. 412, 444, 530, 581. When I gave the gist of their views as outlined further on, Mr. Hambaugh acknowledged that they were about so. I then asserted that plenty of surplus room above, with sections all the way from empty to nearly completed, even over a large brood-chamber, would not prevent swarming, as I had often proven to my entire dissatisfaction. He readily agreed that such was the case. How, then, could the Dadants prevent swarming, as they never extract from the lower story? Then it was that Mr. Hambaugh said the reason, perhaps, was that their apiarist kept a close watch, and, as soon as the bees began to get a little crowded for room, he would raise the super and clap on a box of empty combs. I said, "I suppose, then, the idea is, that an entire super of empty cells, ready to rush the honey into, keeps the bees occupied and satisfied, keeps the honey out of the brood-combs so that they never become crowded, and thus keep down the swarming impulse." He replied that that was about it.

Now, please do not conclude that I am assuming too much. Just wait till I get through. Here are two propositions, as I have given them, worth thinking about, and I ask you to please follow me as I briefly discuss them. Let us see whether there is not a great deal more than mere capacity involved in this subject.

First, we must remark that, in simple terms, it is natural for bees to swarm. It is nature's plan to fill the earth with bees. To bring about swarming, the Author of nature has enacted certain laws. Here are some of her laws; and, for the sake of brevity, I quote or adapt from the series of papers I have mentioned, without further reference:

"The swarming impulse is the general restlessness of prosperity and enterprise, and the consciousness of powers within, which are not being fully occupied." The thing that most induces swarming is a "turgid condition of the vessels in the bee-anatomy in which are stored the supplies for future brood-rearing." This turgid condition is due to the fact that there is an undue proportion of house-bees to brood requiring feed, caused by the bees storing honey in the brood-nest. Meanwhile, this state of things causes a check of egg-production, which in turn causes the blood of the queen "to assume a peculiarly enriched character"—intensity, I should say. These are some of the conditions that impel bees to swarm out—a sort of hydraulic pressure.

I cite these views because they appear to me so evidently correct. If honey could be kept out of the brood-nest, and really allow the queen unlimited capacity, this state of things might not occur. But we know too well, that, when honey is coming in to any great extent, if there is no store room above, except as the bees build combs they will store it in the combs below—aye, and seal it up too. Who, that has often examined a brood-chamber which a swarm has lately left, has not generally found a preponderance of sealed brood, freshly sealed honey in the outskirts of the brood-nest, and many cells, singly and in groups, amid cards of sealed brood, filled with honey? This crowds the field-bees, and adds another element of discontent. It is altogether a cramming, crowding, pushing, driving process.

Now, don't you see where the value of empty combs comes in? Why, there is a vast system of storehouses above, already built, ready to garner the inflowing riches. And what can make a field-bee happier than a copious flow of nectar and plenty of room to receive it? It is not the disposition of bees to hamper the queen. That bees, when given combs above at a time when they are crowding the brood-nest with honey, will remove it and store it above, even much of that which they have already sealed, I have ample proofs. Hence the queen is allowed her full capacity; and to feed the larvæ, carry the honey above, ripen and seal it, seems to give the house bees sufficient employment. Thus the swarming fever is allayed, or prevented altogether. Does it not all look reasonable, probable, all but certain? This system, over a small brood-chamber, might not avail to prevent swarming; but I am very certain that a large hive, and working for comb honey, would not do it.

Mr. F. S. Wallace, of Clayton, Ill., like the Dadants, is troubled very little with swarming. I had several of his queens in my apiary last summer, and not one of them exhibited any disposition to swarm, although two of them were run for comb honey, and one of them never saw more than six frames. Such bees are apparently of more contented disposition, less aggressive and enterprising, and therefore, perhaps, if the truth must be told, of less account than the bees of the opposite kind. **Geo. F. Robbins.**

Mechanicsburg, Ill., Mar. 10.

[You have given us a good article, and I hope your position is right. Still, it does not seem to me that the two factors of race of bees and the giving of empty combs at the right time would account entirely for the non-swarming of the Dadant and France bees. You know, that, where bees have unlimited capacity in garrets, they do not swarm much.

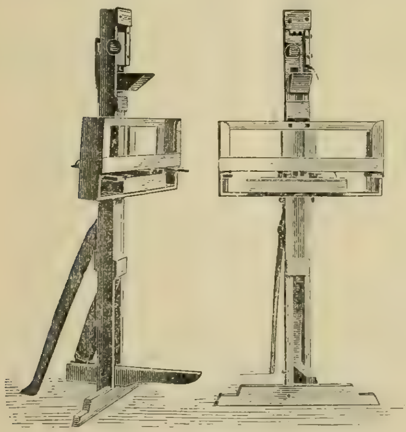
I should like to have the Dadants and Mr. France enlighten us further as to their methods, and how much of a figure their large hives cut in the matter.] E. R.

PHILO'S SECTION-GLUING MACHINE.

A MACHINE THAT PUTS TOGETHER AND GLUES SECTIONS AT THE SAME OPERATION.

I inclose a description of my automatic gluing-machine, for gluing and putting together sections, which I hope will be of enough interest to you and the bee-keeping fraternity to publish in Gleanings.

About four years ago, in the spring, I found, by the condition of my bees, that it would probably be necessary to use quite a number of sections; and after putting some of them together by hand I thought it would be wise to look up a machine for that purpose; and the only thing I could find was a "Manum machine," which I found in my nearest bee-keeper's shop. After using it a short time I could readily see the improvement over the former way of putting them together with a mallet.



MACHINE FOR GLUING SECTIONS.

The Manum machine did its work very nicely indeed; and the thought struck me, if I could devise some plan whereby I could place some glue right in the little grooves of the dovetailed part of the section, without making any extra motions, the machine would come nearer perfection; and in order to do this I found it would be necessary to change the plan and workings of the machine throughout. I soon had the thing figured out in my mind, and went to work to make a temporary machine of pine, which did its work perfectly; and the same little machine made of pine has worked for the past four years for three different bee-keepers, to their entire satisfaction.

A year ago last spring I bought 1000 V-groove one-piece sections for a neighbor, and, after looking them over, he concluded he would rather have the four-piece sections; so I had the one-piece sections left; and when I went to put them together I found my machine was not yet perfect—because I had nothing to glue the V-groove with. The next thing in order was to make an attachment that would glue the V-grooves with the same motion of the foot that presses the box together. I did this by placing a rack in front of the machine that will hold forty or fifty strips with the grooves downward.

Under the strips is a glue-pot with a roller in, and three little beveled-edged wheels on it that turn in the glue; and when the dovetailed corner of the box is pressed together, the bottom one of the section strips is pushed over the wheels, causing them to turn in the glue and in the V-grooves at the same time, thus gluing them perfectly.

The machine from which the photo was taken which I send you was nearly all made of wood. I am now making all the small working parts of the machine of metal.

Half-Moon, N. Y., Jan. 30. **E. W. Philo.**

[While I was in attendance at the Albany convention last December, my attention was called to the fact that there was a man there who had got one of the nicest machines ever invented by a bee-keeper. I have heard this so many times on other occasions before than I did not think much about it. But shortly afterward I was shown the machine, and was introduced to the inventor, Mr. E. W. Philo, as above. In his hands it certainly worked beautifully. He is a cabinet-maker, and a real genius. Well, I have not tried the machine myself, and it is possible that others could not make it work. Mr. Philo is going to send us a machine, and we hope then to try it.] E. R.

THE NONPAREIL BEE-HIVE.

ITS MANAGEMENT.

It has become an axiom among bee-keepers of experience, that, the more bees a colony has at the beginning of a honey-flow, the more surplus it will make. So true is the axiom, that the best hive ever made is worth little without plenty of bees at the right time; and it can hardly be the best hive unless it affords facilities for extensive brood-rearing in spring, and the early development of large colonies. And next, after successful wintering, the most profitable bee-keeping will ever turn upon these points. The flowers may bloom, and the nectar flow never so freely; but it will avail the apiarist little profit unless his hives are overflowing with bees at the opening of the harvest.

To get these large colonies, we must not only have protection for the brood against the cold nights and days of spring, but we can utilize the heat of the sun's rays to very great advantage. The heat absorbed from the sun by an uncovered, well-protected hive, upon a few hours of exposure at midday, will sensibly affect a colony for days afterward. Heat has been said to be life, and the sun's rays do certainly stimulate the life energies of both the queen and bees when applied in the manner stated.

Thus, we may promote extensive brood-rearing as well as the economical use of the stores, which will go much further where proper protection and care are given. I have estimated that a third more brood and bees can be obtained. at a saving of at least 10 lbs. of stores to every colony in spring by the management advised.

The protection given is by packing the brood-chamber in the winter case with excelsior sawdust, chaff, or forest-leaves. But it should be steadily borne in mind, and not forgotten for a moment, that any packing that may be used must be kept dry. Active brood-rearing in spring causes the packing to become damp, which then, instead of conserving the heat, carries it rapidly away, so that the colony would be far better off with no packing at all than a lot of wet material about the brood-nest. Here let me say, I consider fine sawdust one of the worst things that can be used, either in winter or spring, for protecting bees, and all because it will get damp, and can not be readily dried out. The packing must be of some coarse material that the air can readily permeate, and two or three inches of such packing is enough.

UTILIZING THE SUNSHINE.

To get the full benefit of the sunshine, the hive-covers should be removed every pleasant day about 10 A. M., when the bees can fly, or at least every few days, and the packing on top of the brood-chamber taken out, as well as any that may be found damp at the sides. The sun should be allowed to strike full upon the covering of the brood-nest, which I prefer to be a thin (¼-inch) board, cleated at the sides, placed a bee-space above the frames. About 4 P. M. the packing and hive-covers must be replaced.

Now, all this seems like a great deal of labor; but with light covers, and the use of excelsior, I find that it requires only about half an hour each day for the care of 50 colonies, and I do not think that in any spring my hive-covers and packing have been removed to admit the sunshine on more than ten days.

The extent of brood-rearing by this management by the average colony is considerably beyond the capacity of the hives in common use. In fact, the average queen is capable of occupying 1400 square inches of brood comb with brood, while the ten-frame Langstroth hive will contain but 1350. But there is required also two or three hundred square inches of comb for the stores of honey and bee-bread, so that the capacity of the brood-nest for the best results in spring breeding should not be less than 1600 square inches of brood comb. As the common eight-frame hive will contain but a little over 1000 square inches of comb, it will be seen that one such brood-chamber is quite too small, and two of them quite too large. When we use two of the Nonpareil brood-chambers in spring breeding we have the requisite capacity. As one storey* is just right for a swarm for the best results in working for comb honey with a queen-excluder, it is plain that the proper remedy for the eight-frame hives in use is to cut them down so they will take a 7-inch brood-frame; then make winter cases for them, and bee-keepers will speedily get on the road to profitable apiculture.

The spring management of bees requires care and attention, aside from the foregoing, that they have plenty of honey or its equivalent—sugar syrup. Every colony should have at least 10 lbs. on hand all the time up to near the time for the honey-flow to begin. Unless this is attended to the brood-rearing will be limited, and all the care given will prove unavailing in getting large colonies by the first of June, when the harvest usually opens in this locality. For spring feeding, Cutting's atmospheric bee-feeder is probably the best in existence. It may be used at the entrance, or over the brood-chamber. It is best used at the entrance to stimulate brood-rearing. No robbing or daubing or drowning of bees can take place, and I am surprised that an invention so useful and handy as this one should not be more extensively used.

Owing to the fact that, in a two-storey hive, the bees always begin brood-rearing in the upper storey in the spring, the progress of the egg-laying of the queen is the same as in the old box hive. No spreading of the brood or fussing with the brood-nest is ever necessary, except where building up a colony in adding a second storey. By the above management our colonies will have from 70 to 80 thousand cells of brood at the opening of the harvest, instead of only 40 or 50 thousand possible in the common hive; and every expert bee-keeper knows what this will mean. My next will tell how to get comb honey. Dr. G. L. Tinker.

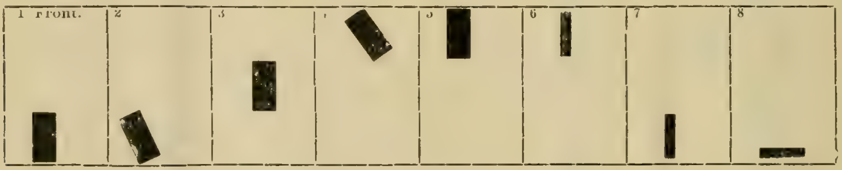
New Philadelphia, O.

To be continued.

THE BRICK RECORD.

CARNIOLANS.

The article by C. A. Hatch, Feb. 1, reminds me of one of many neglected duties; viz., calling attention to this method of keeping a record of the apiary. I have practiced it for about six years, and will testify to its great value. The great advantage it has over others is, that the apiarist can stand in one spot, and, by simply casting his eyes along the line of hives, see at once its condition; and if he sees a swarm emerging from a certain hive, he knows at once whether it is a first swarm or an after-swarm. If it were not useful at all as a sign, I have always considered a brick on the lid of a hive a necessity to keep the lids from blowing off in high winds; and in queen-rearing, of importance in preventing nucleus hives from blowing over. My method has required but one brick, and I will give you here the different positions of the brick which I have found to answer every requirement, either for a honey apiary or a queen-rearing apiary.



MORRISON'S METHOD OF KEEPING RECORD.

FRONT OF HIVES.

No. 1. brick parallel with and on the rear end of hive, "Has fertile queen, and in working order."

No. 2, brick on rear, and at 45° angle, "Queenless."

No. 3. brick in center, parallel, "Gave queen or cell."

---

* Dr. Tinker requests this spelling.—Ed.

No. 4. brick on front, at 45°, "Queen accepted," or "Cell hatched."

No. 5, parallel on front, "Swarmed."

No. 6, parallel on edge or front, "Queen-cells."

No. 7, brick on end, "Immediate attention; needs feed; take honey; fertile workers."

No. 8, edge across rear of hive, "Neither queen nor brood."

Besides this, on one corner of the lid, in small letters, I keep such a record as this: "Tested queen, June, 1890." "Swarmed June 1, '90." "Removed queen May 10, '90." "Larva given, May 28, '90." "Give 1 qt. syrup." Each season these lids are freshly painted, and a new record begun; but the age of the queen is always preserved.

It is scarcely necessary to give any system of using the brick as a sign, only to illustrate the method; for if any one will only begin by using a brick in one position to indicate one thing, all the system needs to indicate every thing the bee-keeper desires will follow in turn.

CARNIOLANS.

I am not now and do not expect again to be in the queen-rearing business. Having also sold my entire apiary of Carniolans at Oxford, Pa., I can now give my opinion of Carniolans as a disinterested person: The only fault that has been urged against them with any show of reason at all is, that they swarm too much. Well, the same has been charged to every other race with just as good reason, as I well know from experience. I am very sure it is a more prolific race, and they are better honey-gatherers. Give a colony twenty, or, better, thirty brood-combs in a Simplicity hive about the middle of April, and on the first of July extract all, and compare with any other race as to honey gathered; and if the start was fair, the product of the Carniolans will be ahead.

S. W. Morrison.

Colorado Springs, Col., Feb. 6.

DAYTON'S QUEEN-RESTRICTOR, AGAIN.

DAYTON'S REPLY.

If I remember correctly, I sent to you two articles—one upon the queen-restrictor, and the other upon contraction alone. You published my article on contraction, gave the illustration of the restrictor, and, in the foot-notes, wrote in reference to the restrictor from a contraction view, and not from a restrictor view, as you may see from my references. What my article said about contraction doesn't do justice to the restrictor.

You say (in foot-notes, p. 168), "It is considerable of an art to manage so as to make contraction a real benefit," which I agree to; but I think that, what is art or science now, will, by use and practice, become ordinary, and not be deemed as extraordinary. The earlier the study is begun, the sooner learned.

You say, "An unlimited capacity is quite apt to discourage, if not prevent, all swarming."

You did not notice that the restrictor is provided with a reversing device wherewith the queen-cells may be inverted to prevent swarming by their being destroyed before they are mature. My restrictor is reversed the same as your single combs are reversed—the five combs being handled (and even may be considered) as one comb. Forty colonies may be thus manipulated in the space of one hour. If the frames were inverted singly it would require four hours for forty hives.

You ask whether my restrictor "is not a good deal of work." You have the queen-cells, queen, etc., all in a shape so as to reverse with the same labor that is required to reverse one single reversible frame.

Reversion causes as much brood to be reared upon my five frames as is usually contained on seven or eight; and this brood is mostly included in the restrictor.

You appear to think that my zincs between the top, bottom, and end bars are numerous, and require taking off often. When the frames and zinc strips are once put on they are *almost* never removed; but the *side sheets* are easy of manipulation, and require adjustment once each year—just before and after the harvest. A bee-keeper visited me a short time ago, to examine my restrictor, and said:

"Why, Mr. Dayton, it would be a great deal of work to take off and put on these *hoop-like* strips of zinc often."

I asked, "Why would you take them off?"

He answered, "To find the queen."

"What would you want the queen for?"

"To clip her wings."

"Why clip wings?"

"To prevent her going off to the woods."

"How could she get out of the cage to go to the woods? and how could bees swarm when the reversion of the combs destroys the queen-cells?"

"I did not think to study that out. Why, you would never have a swarm in the world, with such an arrangement."

Let the queen remain unclipped. The restrictor will reverse quicker than you could clip a queen's wing, even if you have her already caught.

In the notes, the Dadants and Mr. France are quoted as using unlimited space. But you forget that they are principally producers of extracted honey — when reversion, contraction, and exclusion, are more applicable in the production of comb honey. Mr. O. O. Poppleton was the most successful honey-producer in my locality—using a 26 or 30 frame hive for extracted honey; but when he changed to the production of comb honey there was a very great change in the size of his hives, to a small size.

I find no reason for handling brood-nests frame by frame, but all together—several frames at once. This handling the frames severally, by learners, is more curiosity than necessity.

As to Heddon hives being less labor, it is as easy to attach my sheets of zinc as it is to put on the honey-boards you speak of; and my plan enables me to retain the old suspended frame as Mr. Langstroth gave it to us, which is the frame in size or form that will outwear and outweigh any other frame that will ever be invented.

C. W. Dayton.

Clinton, Wis., March 20.

[The first paragraph calls for explanation. By an oversight, the engraving appeared with the contraction article rather than with the one on queen-restrictors. As the latter did not appear, and as the former *involved* the subject of restrictors, I concluded that the cut belonged to it.

I am very glad to give place to Mr. Dayton's article, as above. As it covers most of the points brought out in the other article, it will be sufficient. I thoroughly indorse the idea that he emphasizes in the next to the last paragraph; namely, that there is "no reason for handling the brood-nest frame by frame," and that they should be handled "all together—several frames at once." Mr. Heddon deserves credit for emphasizing a similar plan. In a majority of cases, with the Hoffman frame, and also the closed-end Quinby, I am satisfied that a satisfactory knowledge of the interior of a hive may be obtained by handling three or four frames at a time—that is, I mean in the production of honey. I have no doubt that friend Dayton can get along in a similar way with his restrictor.

If my memory serves me right, it was decided in the Question-Box that reversing does not invariably destroy queen-cells. How is this, friends?] E. R.

KEEPING A RECORD OF QUEENS.

FRIEND M'INTYRE TELLS US HOW HE DOES IT.

Californians have been feeling a little blue for a few months on account of the absence of rain, hence a scarcity of articles from this quarter. The rule is, no rain, not any thing—not even words; but we have just had 8 inches of rain in 36 hours; and although bridges and roads are washed out, and trains stopped, the faces of the people wear a smile. We can go to work now with some heart, to prepare the bees for the coming season. Clean up your apiary and make it look nice before commencing to overhaul the bees. You will feel happier at your work if the surroundings are pleasant. I find every queen in my apiary in the spring, before the bees get very strong, and clip every one not clipped. I know positively, that every queen found without her wing clipped was reared last season, and mark her in my record-book as one year old, although her birth-day has not arrived yet. The age of every queen found with her wing clipped is advanced one year; and those marked two years old are usually superseded near the close of the season.

Hive No.	QUEEN.				C'bs br'd	Lbs h'n'y
	Str'in	Age.	Gr'de	REMARKS.

23	H.	1	x	Breed.	6	40

This is a page from my record-book, and contains all the record of queens I care to keep. It is small enough to carry in my pocket. When I had few colonies I kept a larger book and gave more space to each colony—often a whole page. As my apiary increased, my record decreased until I got a whole row of 23 hives on one page. My apiary contains 22 rows, and each row is lettered. When I wish to find the record of a certain queen, I place my thumb on the letter on the margin of the book corresponding to the letter on the row, and open the book instantly at the right place. Every hive is numbered. The numbers run from 1 to 23 in each row, and are kept on a piece of board 4x10, driven into the ground by every fourth hive. The letters representing the row are also on the stakes just above the numbers. The page almost explains itself. The different strains are marked with letters—S for Syrian, H for Root's honey strain, etc. The next column gives the age, 1 or 2 years. I often keep breeding-queens three years. The next column gives the grade or quality. I make 4 grades—X for extra, 1 good, 2 medium, 3 poor. Remarks explain themselves. The brood and honey columns only serve to equalize in the spring, and are not kept up through the season. I should take 20 lbs. of honey from No. 6, and give it to No. 21, and a comb of hatching brood from No. 20, and give it to No. 18, and that row would be all right.

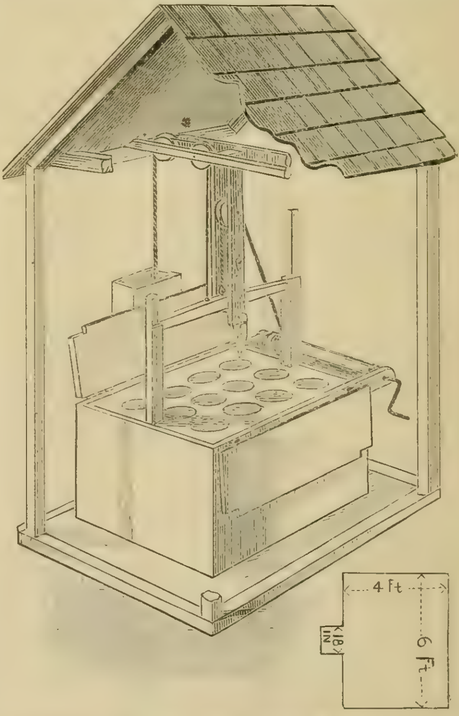
I have a system of book memoranda for queen-rearing, which suits me much better than slates, cards, stones, or bricks, on the hives. My apiary is 150 feet wide and 300 feet long, over an acre, and it takes too much time to find the colony that needs attention by any system of marking on the hives. But I can write about any thing better when I am working with it; and as this article is already long enough I will leave it for another time. J. F. McIntyre.

Fillmore, Cal., Feb. 24.

A DAIRY WELL.

HOW TO MAKE ONE.

I have never been north, and I don't know what the needs of the people are on the farm; but I do know that every Southern farmer needs what I have termed a dairy well. The originator of the idea is Mr. Wm. Bibb, of Westminster, S. C., formerly of Bartow Co., Ga. I am aware that this is a little out of the line of a bee-journal; but milk is closely associated with honey, in the Bible, and, in fact, I like them



A SUBSTITUTE FOR ICE-HOUSES AND REFRIGERATORS FOR WARM CLIMATES.

pretty closely associated at the table, with a little butter thrown in. Besides milk, this well is good to keep pork or other fresh meat in, in summer, away from flies; also to keep any thing from freezing in winter.

For ordinary use the well should be dug 6 ft. by 4 square, with a gutter, or groove, down one side, 18 inches square. It should contain two or three feet of lasting water. It should be in easy reach of the kitchen, and attached to the house if possible. The curbing should be no larger than the well. A platform, which fits inside of the well, slides up and down between two timbers, which rest on the bottom of the well, and are long enough to reach up 3 ft. above the curb. These two timbers should be planed. The framework of the platform has a board nailed on each side of it, forming a groove which fits on the upright timbers at each end of the well. This makes it rigid, and keeps it level. The circular black spots on the platform represent openings for vessels. The piece that holds the wheel, over which the rope passes to the windlass, is prolonged so that, when the platform is just even with the top of the curb, an iron pin is inserted through it and the top-bar of the platform frame, and holds it there. There is another rope, and two wheels. This rope has a heavy weight attached, to assist in raising the platform from the bottom of the well, with heavy loads. These weights go down into a box formed of four wide planks, which occupy the gutter, or groove. One lid opens up against the weight-box, and fastens with a thumb-button. The other is hinged so as to hang down by the side of the curb when open.

I think what I have said, and the sketch, will make it plain. R. W. J. STEWART.

Sonoraville, Ga., Feb. 2.

[Friend S., you have given us something of very great value, I am sure. The custom of letting down a pail of butter and other kinds of food into the well, to keep them cool, is almost as old as the hills, and I have several times wondered why somebody did not invent a dummy or elevator to run provisions into the cellar, or, still deeper, into a well, where ice is not to be had, or is inconvenient; and most farm homes find it a good deal of trouble to have an ice-house simply for their own use. It is my opinion, however, that, to have the water real cool and nice, it should be used for watering stock or something of that sort. I saw a statement recently in one of our agricultural papers like this: A certain well gave such cool nice water that it had a reputation for some distance around. As this well was close to the house, however, and some distance from the barn, the owner dug another one by the barn, for greater convenience in watering his farm stock. As soon as they stopped drawing heavily on the water near the house, however, it began to get warm and insipid, and the water at the stables improved in the same proportion as they began to draw on it. This taking water away, or removing it from the well, produces a running stream or running spring. Of course, the cheapest way to get this superfluous water out of the way is to do it with a windmill, providing you can afford the first expense. By the way, friend S., why would not the arrangement you have given us take the place of a cellar to a considerable extent, and at the same time save the good wife the labor of running up and down stairs? Another thing: A good many have discovered that rain water is more wholesome for them than the hard water from many of our wells; therefore you can catch your rain water from a roof in clean vessels, and then let it down into a deep well to cool.]

DEACON HOMESPUN AND HIS "KNOWIN' BEES."

ALSO SOME OF THE DEACON'S PLAIN-SPOKEN OPINIONS IN REGARD TO "BRO. RUTE."

Having been a reader of GLEANINGS for the last 13 years, I have become very much pleased with it and attached to it, and I often recommend it to others, and have now and then induced one to subscribe for it. But I found one who did not want it at all. I went over to Deacon Homespun's to make a call, see his bees, and I naturally asked him to take GLEANINGS. He said that he did not want it, for the reason that he had decided "not to read any more of Rute's writing till he wrote something kinter interestin'."

I remarked that *I* considered it all *very* interesting. Well, he said that he "had got Rute's A B C book, and did not think much of it."

"Why have you arrived at such a conclusion about the A B C book?"

"Wal, ile tell you. Now, he says a great deal about interducin' of queens; and I don't think much of his way, for I have got a way that beats it all holler."

"Now, deacon, have you any objections to telling your plan of introducing queens?"

"No, sir, I hain't. It is this: When you have a queenless colony, jest hang in a keard of brude, and the bees will raze a queen right there in the hive. Now, don't you see that this way will save all this fussin' about interducin'?"

"Yes, deacon, that is very true. You can get a queen in a hive by placing in the hive a card of brood, and the queen will hatch there and *be there* without much trouble, etc. But you see the honey season is short; and while you are waiting for your queen to hatch and get ready to lay, much valuable time is lost so far as *that* swarm is concerned; for, you see, it takes about a month after the queen commences to lay before her bees are ready to work; therefore by that time the swarm will be very small, and be of little profit to you for that season, for the old bees are all the time dying."

"Well, that ain't the case with *my* bees—they don't die off fast at all."

"What kind are your bees?"

"Well, they are a mixture of bees from the Southern States, with *my* kind. You see, a few years ago I lost most of my bees, and in the spring I sent south and bought some to make up my loss in the winter."

"Did you get *queens* with your bees from the South?"

"No, I only jest got bees, and put with mine. I *had* queens."

"Well, don't you know that the bees you had from the South soon died, and therefore you had only *your* kind as you had before you bought?

"Now, deacon, I see you have the two-story Root chaff hive. How did this happen?"

"Well, you know I told you that I had Rute's A B C book, so I took the book to a shop in town and had all of my hives made accordin' to the book."

"Well, then, you *do* think something of Mr. Root's writing, after all; so I will leave a copy of GLEANINGS with you; and when I come again I hope you will have decided to have it mailed regularly to you."

As I handed it to him he said, "I think that Rute is a kinder of a big *I* and a little *u*," at the same time pointing to the foot-notes.

"Now, deacon, as to the remarks of Mr. Root that you now refer to, I think I can say, without fear of contradiction, that his readers would not have that part of the matter left out on any account. But, again, in regard to the chaff hives you use, I see you have them all numbered on the front side with large figures, which I consider a good plan on several accounts. One is, if you wish to refer to any one hive you can do so by its number."

"Wall, I will tell you what I had it done for. It was so the bees could tell their own hives."

"I don't know, deacon, that I fully understand you. Now, there is *22* and *23* side by side; do you think your bees can tell 22 from 23?"

"Well, I don't know about *your* bees or *other* folkses; but *mine* can tell 22 from 23 *every time*. *My* bees know more than you may think they do. They know me when I come around, every time. Sometimes I lay down on the grass, watchin' for them to swarm, and sometimes a bee will come and buzz all around me. They will look in my *eyes* and in my *ears*, and look me *all over;* then they goes away. Sometimes when I am comin' from town they will come and meet me, and fly all around me."

"Well, I shall have to bid you good-by; but I want you to read GLEANINGS; and when I call again I hope you will like it well enough to subscribe for it." W. S. WRIGHT.

Battle Creek, Mich., March 18.

[Friend W., will you please make the deacon a present of GLEANINGS for a year, and tell him that "friend Rute" sends it willingly as a return for his very candid and outspoken opinion? By the way, that last expression of the deacon's is a gem. I can imagine every reader of GLEANINGS, who has had a few summers' experience, leaning back in his chair and taking a good hearty laugh about those "knowin' bees." Sometimes they meet us on our way home, and look into our eyes and ears with more inquisitiveness than is really comfortable; but if the deacon enjoys it, we are very glad.]

NOTES ON RECENT DISCUSSIONS.

COARSE WIRE CLOTH OVER ENTRANCE IN WINTER, BY REV. T. C. POTTER.

A recent question propounded to the Solons of the apiarian fraternity, was as to whether it is advisable to use wire cloth over the entrance, when wintering in the cellar. After an experience of ten years with a small number of colonies each year (I can handle only a few and be faithful to my regular duties), I am led to the belief that bees winter nicely in a dry cellar when coarse wire cloth is used over the entrance. About putting it across the bottom and top, I can not say; but in my own case I have never taken either bottom-board or cover off. Simply put a good, dry absorbent cushion over the frames, lay the honey-board over it to keep it smoothly down, adjust the cover, bend a length of wire screening to fit the entrance all along, and it is done. At any time if you wish to feed at the entrance, as spring approaches, slip the screening away and lay your feeder there. I have found only a little feed necessary in spring, to start the queen to laying. For two weeks before the date of this writing, our thermometer has been about zero every night; and yet upon examination I find that I am well stocked with brood. I have never lost a single colony, nor observed any but good results. Fixed thus, they have plenty of air, do not ramble out and die on the cellar floor, and the mouse-pest question is settled. Extensive apiarists may find a removal of the bottom-board necessary to crate the hives rightly in the cellar; but for those having only five to twenty colonies, like myself, it is not necessary. If there are some dead bees on the bottom-board, as there usually are, I simply keep a bent hook of wire, and, removing the screen occasionally, draw them out.

ARE CELLAR-WINTERED BEES MORE SENSITIVE TO THE COLD WHEN SET OUT IN THE SPRING?

I believe it to be a little more than a notion, that bees wintered in the cellar where the thermometer ranges from forty to fifty will be more sensitive to cold and changes when taken out in the spring. Apiarists must remember that bees are not like human beings in this respect, and so we can not judge them by ourselves. The good Lord, who has made every thing right for its own conditions, has provided our bees with an instinct as well as aptness for hibernation; and when a cold spell comes they pass into stupor such as renders them largely insensible to the cold or changes. A good hive, plenty of stores, and care upon the part of the keeper, are all the specifications necessary, provided the queen is fruitful and the bees ordinarily numerous.

A PECULIAR EXPERIENCE WHILE WORKING AMONG THE BEES.

For some years I have been studying my own physique as it has been affected for better or worse by my work among my bees. I have found that breathing the strong, acrid odor that comes from a newly opened hive in summer, when there is unripened honey in abundance, gives me a catarrhal cold every time. I call it this, although I can check it at once by snuffing tepid salt water up the nostrils. Without this treatment I should have a "cold in the head" for two or three days. Some one may fancy it is due to getting into a perspiration and then cooling off too quickly. That occurred to me at first; but with experience I have found that it is not due to any thing except the acrid fumes from the bees and hive. Has any other bee man or woman ever observed this effect? It is very quickly and invariably done in my own case, even if I inhale much of the odor from an observing-hive in the house.

AMMONIA FOR GETTING PROPOLIS OFF THE FINGERS.

A lady recently spoke of the necessity for gloves, because of getting propolis on her fingers and under the nails, and having difficulty in removing it. If she will take her bottle of good strong ammonia, and a cloth, and rub gently over the soiled finger, getting some of the liquid under the nail, she will find that this alkali will turn the propolis stain a sunflower yellow in a moment after it is put on. After this treatment, don't be in a hurry, or frightened at that worse stain. Let the ammonia act a moment or two; then wash well with soap and water, using a nail-brush if necessary, and all will come off nicely.

A CAUTION AGAINST CATCHING COLD BY USING THE WATER TREATMENT.

Is it not well to caution your readers about taking cold, after making use of the warm-water treatment, of which you addressed us at length in GLEANINGS for March 1st, particularly if it occurs in the ordinary place out of doors? When hot water is used, perspiration ensues—especially if more than one injection is taken, and absorption through the kidneys and internal membranes is occurring. T. C. P.

Cedar Falls, Iowa, Mar. 14.

[Thank you, Bro. P. I knew all the while when our big guns (begging their pardon) were telling us that wire cloth over the entrance would not do, that they were not quite orthodox. Thanks for your suggestion in regard to propolis, and also for your caution. I have taken cold once in the way you suggest, but since then I have been more careful.]

OUTSIDE CASES FOR WINTERING.

J. A. GREEN REVIEWS THE MATTER.

If there is one thing more than another that I have felt disposed to criticise in the way GLEANINGS is edited, it is, that, in your foot-notes to articles, you seem to think it necessary to find some fault with the ideas therein presented, and that, under the pressure of this seeming necessity, objections are made, that, while usually real and vital ones, are often unimportant, to say the least. Your supposition that snow would beat under my covers of corrugated iron is well taken. It would be a real objection if it were true; but I am happy to say that I have not had the least trouble from that source. I might, perhaps, if it were not that the cases are filled to overflowing with packing material, upon and into which the corrugated cover is crowded tightly, and then *held* there.

But when you find fault with the board and stone as too much rigging, I must smile. The stone is all that is really necessary, though there are few bee-keepers who can not easily find some kind of board eighteen inches or so long for each hive, and duplicate them every year if necessary. Some of my covers have a strip 1x1½, nailed across each end of the sheet. With these the cross-boards are altogether unnecessary, and the stone may be replaced with hooks, or something similar; but I do not like them, as they are more expensive, and because they can not be nested together. With the plain sheets, twenty-five may be stored away out of the weather in the space that one of your covers will occupy. The stone, or its equivalent, I regard as a necessary part of each hive's furniture, summer and winter. I have some large paving-bricks that are a little more ornamental.

When it comes to looks, it may be that my packing-case might be improved upon—at proportionate expense. I must confess, though, that, while I take some pride in the appearance of my apiary during the summer, I do not care quite so much about its looks in the winter. A mantle of snow softens and beautifies all harsh outlines; and if there is none, the severe plainness of the packing-cases is only in keeping with the general bareness and desolation of objects of nature. Still, if the cases are made of better lumber, and painted, they may be made to look very neat.

I doubt very much whether a good cover can be made that will not cost much more than the corrugated iron, especially when durability is considered. Painted muslin *may* do. I have never tried it; but I think it would be found unsatisfactory, and, in the long run, expensive. Roofing-paper I have tested thoroughly. It is undesirable, except for something cheap and temporary. The material for a tin roof costs as much as the iron, besides the expense of making it.

Your cases, allowing only ¾ of an inch on each side for packing, are not nearly large enough. It is well enough to talk about putting the packing material into a cushion in the shape of a thin ring, to go within this ¾-inch space; but did you ever try it?

I do not think the "dead-air space" at all practical. Theoretically it is all right when it *is* a dead-air space; but in practice this can never be secured, and can only be approximated at greater cost than packing. One very real advantage of packing is, that, in the spring, it absorbs heat from the sun during the day time, thus keeping up the temperature of the hive at night. If you want to test this, take two vessels of glass, tin, or any thing you choose. They should be air-tight to make the experiment conclusive. Fill one with sawdust, and leave the other empty. Put them in an oven or other warm place until they are thoroughly heated through; then put them in a cool place and see which retains heat longer.

I have just received a letter from M. M. Baldridge, in which he says: "The Oatmans discarded cellar wintering (say ten years ago), and thereafter left their bees on summer stands, packed in large boxes with chaff on all sides. . . . . . Their packing-boxes were made large enough to hold four colonies, and they had an entrance on each of the four sides. They put up their bees thus very early—say in September or October, and did not remove them from the packing-boxes until June following. . . . . . The Oatmans wintered bees thus for several winters with fine success. They are now nearly out of the bee-business; but if they were to begin again they would pursue the same plan. At one time they had some 700 colonies scattered about the country. . . . . . Their packing-boxes had bottoms, were made of cheap lumber, and cost about $1.00 each."

The Oatmans, I suppose you know, were very successful honey-producers at Dundee, Ill. They are now owners of several creameries, I believe. J. A. GREEN.

Dayton, Ill., March 10.

[If I criticise in a foot-note I do not do so for the sake of it. I do not *intend* to make any criticism unless there is something that appears as a *real* objection. Very often, to call out further discussion, I enter a criticism in order to get the writer to elucidate a little more fully. I did not do so with that in view in your last article; but whatever the intention was, that foot-note has called forth a valuable communication in defense.

This time, friend Green, I shall have to assume the defensive, as you assume the offensive. You have cornered me up in several places, and I do not really know whether I can get out or not. Now, then, to the points of your article:

I am glad to know, that, while the snow would apparently beat under the covers, it does not in reality. So, my criticism No. 1 is washed out.

About that board and stone. I may be wrong, but I still *hang* to the point that they make a good deal of extra rigging. I know there are a good many practical bee-keepers who use them. They want them summer and winter. But when you add to the toil of going through the *whole* apiary, by lifting off a ten or fifteen pound stone for *every hive*, you add just so much to the cost of producing a pound of honey, to say nothing of the extra labor and wear on the man. We have never used stones in our yard. It is only rarely that we have winds that lift the covers off the hives; and W. Z. Hutchinson, of the *Review*, expresses himself in a similar way. Perhaps this difference of opinion might be explained by locality.

As to looks, I do not know that I would urge that point very hard. Your outside packing-cases, I must admit, are rather pretty than otherwise, although I am opinion that a case such as I have described would look neater. After all, it is not looks, but dollars and cents, we are after, in bee-keeping, so I will yield to you on that point.

Now about that air-space. At first I did not think it was possible to maintain practically a *dead*-air space; but those outside cases that I described, made of ⅜ lumber, and dovetailed, with a tin cover, will, I think, hold water. When they were put together I told the painter to be sure to chink in paint wherever the joints seemed to be possibly a little loose, and he did so. Now, these outside cases are pushed down into a banking of sawdust, which, being more or less wet, freezes around the outside bottom edge of the case; so you see that we have, practically, a dead-air space. In time these cases might, however, get a little leaky.

Now as to results. So far in our apiary we can detect no difference between the air-"packed" and chaff-packed. Yet I will admit that, before spring, we may see a woeful difference. I might say further, that, on account of dysentery, three colonies died in chaff hives, and one died in dead-air-space hives. Still, one straw does not show which way the wind blows. I consider it only negative testimony; that is, so far there is nothing particular *against* the dead-air space. I have never tried the experiment, but I believe the packed space will cool slower than the air-space. But, mark this: We want all the sunshine we can have. One writer—I do not know who it was—intimated that air-spaces were better because they would warm up quicker, and so give the bees a chance to turn over in their dose. You see, this fact will partially compensate for the extra protection of packed spaces.

About those rings of packing. No, I never tried them—that is, not exactly that thing. You know I spoke of this as being one of the provisional things. If the thing worked successfully here at the Home of the Honey-bees, it is no sign that it would do so in other localities. I merely outlined a few things that I wanted to test, and I wanted others to try, and this was one of them.

Now, friend Green, I thank you for your criticisms, and I am quite willing to have my air-space idea snowed under. *My* air-space, did I say? No, I do not quite mean that. It is a very old thing that I have been reviving of late, just as I did thick top-bars and fixed distances.]

E. R. R.

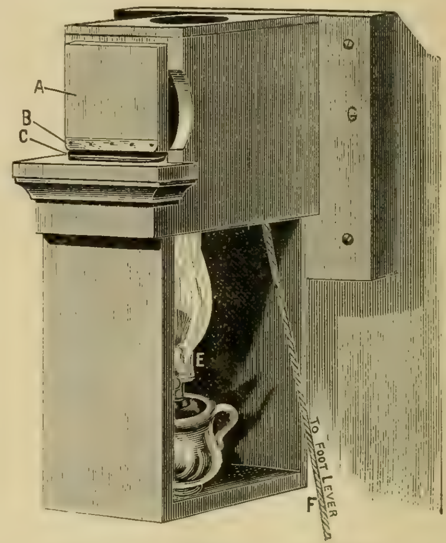
THE HAYES FOUNDATION-FASTENER.

A GOOD MACHINE.

Friend Root:—As per request I herewith inclose a photograph of my foundation-fastener. I can imagine some one exclaiming, "This is an improved Miller machine, as the principle is a metal plate." But the fact is, I claim entire originality, not knowing that any other persons were working or had worked on the same line. How true the saying, "There is nothing new under the sun." Really, I imagined I was going to present to the fraternity something that would certainly place me in an enviable position among the great in bee culture. I had already imagined myself in one of those beautiful half-tones in the leading apicultural journal of the world, including an autobiographical sketch of the inventor. But, alas for my fond hopes! Miller gets there, and I am left.

But notwithstanding, I claim the only practical machine extant. The model was constructed over a year ago. I have since manufactured several for supply-dealers and practical apiarists, and they are pronounced by all an unqualified success. The rapidity and perfection of its work are astonishing. I can readily put in 10 full sheets in one minute. This is about as fast as one can handle the pieces, being perfectly centered in the section, and I defy one to be loosened from the section without tearing it off. For putting in foundation *a la* C. C. Miller, 3¼ at top and ¾ at bottom, it works to perfection. It requires no warming preparation of the foundation. It simply should be warm enough to bend without breaking. Its work during the winter months, when other methods are so annoying, is simply perfection.

The most important feature of the machine, as compared with any other in the same line, is the guide-block, which centers the foundation without any effort from the operator. The steel plate *c* is controlled by the treadle, not seen in the picture; consequently it is adjusted on the floor at the right of the machine. The plate projects below the head-block *a*, sufficiently far to extend beyond the center of the section. There is beneath the plate space, so that, when a section is placed on the guide-block, it passes beneath the steel plate. The contact of the hot plate with the wood is controlled by the treadle, as you can hold it back until you desire to use it. But I find the instant occupied in picking up the foundation gives the section the proper warmth to cause perfect adhesion. The foundation is picked up between the thumb and forefinger of each hand, and the lower edge is pressed against the guide-block, coming in contact with the hot plate, which is instantly withdrawn by pressure on the treadle; at the same time the foundation is dropped on the section, firmly adhering to the same. I consider this the only correct principle by which to fasten foundation.



HAYES' FOUNDATION-FASTENER.

Mell R. Hayes.

Washington, Kan., Nov. 20.

[Our experience with machines for putting foundation into sections by the aid of a sliding heated plate or tongue has not heretofore been satisfactory. But Mr. Hayes sent one of his machines, with a request that we give it a trial. We did so. It does the work neatly, rapidly, and accurately. It has this advantage over machines that *press* the foundation into the wood, *a la* Clark, in that there is no foundation wasted—an edge turned over and pressed into the wood. Your humble servant, E. R., tried it a good deal; and although it worked rather hard (through no fault of the principle, however, but because the working parts were a little tight) I felt satisfied there was something in the principle. I said, when I first looked at it, that it was copied after Arthur C. Miller's machine; but Mr. Hayes' letter shows that he also was original. It has the advantage over the Miller machine in that the block A guides the foundation to the center of the section.

Briefly, the mode of operation is this: A section is slid under the tongue C, and all around the block A, the latter being just half the width of the section. A strip of foundation is picked up, and held against the surface A. The foundation is allowed to slide down and strike the heated tongue C, which, being withdrawn by the treadle, in connection with the cord F, leaves the foundation with a melted edge when it strikes the section. In an instant it cools and adheres.

The principle is all right; but the machine as made, it seems to me, is a little expensive, and possibly may be simplified a little more than this.] E. R. R.

CONTRACTION AND COMB HONEY.

THE RIGHT AND WRONG KIND AGAIN, AS DISCUSSED BY DOOLITTLE.

I wish every reader of GLEANINGS would turn again to page 167 of the present volume and read the first part of C. W. Dayton's article on contraction. It is a rare thing that so much truth is brought out in so little space. I know nothing about his "queen-restrictor," and do not refer to that part. I have been very much surprised to see the grounds taken of late in GLEANINGS by its managers, to the effect that contraction methods tend to give only a medium force of bees in the honey-harvest, while all that I have ever written on the subject, and the most I have seen, has been to prove that the contraction plan, if rightly worked, will give a "rousing colony" during the honey harvest, as Mr. Dayton says, and as few bees at all other times as is consistent with having this rousing colony just when we want it. For the benefit of the younger readers of GLEANINGS, and to brush up your memory a little, Mr. Editor, let me say a few words as to how I manage bees on the contraction plan, to secure a large yield of comb honey. As the older readers of GLEANINGS will remember, I formerly worked my bees on the side and top-box plan combined, therefore all of my hives are two feet long inside, while the brood-chamber proper is only 13½ inches inside, 5¼ inches on either side of this being set apart for the side boxes, which, added to the 13½ inches, makes the two feet. Since I adopted the lateral plan of working for comb honey, as described in a late number of GLEANINGS, each of these side-box apartments is filled with chaff, or has a chaff cushion in there, so as to shut the bees out and protect them for winter. When spring arrives, the bees in these hives thus fixed are stimulated to rear the greatest amount of brood possible, by one or all of the known plans to accomplish this object, till the nine frames which fill the brood-chamber proper are filled with brood. As the weather is always changeable in the spring and early summer, the chaff packing is a great help to the bees, by way of enabling them to maintain an even temperature, and thus the hives are filled with brood a little earlier in the season than they otherwise would be, as all know who are now recommending chaff-packed boxes for single-walled hives as soon as set from the cellar. To digress a little:

I must say that I think those who are telling that an air-space is as good as a space filled with chaff or straw are making a great mistake. Let me prove it to you. On several occasions, from ants working in my packing, and for other reasons, the chaff or fine straw was taken out of one side, or perhaps one side and one end, during the summer and left out till cold weather came in the late fall or early winter. At this time, when I came to pack these vacant spaces I invariably found the bees clustered up against the side or sides which were packed, and away from those where the packing was removed. If the packing was removed from one side I would find the bees clustered in a half-sphere against the opposite side; if removed from a side and an end, the bees would be clustered up against the inside opposite corner, lying right up against the wood along the two packed sides as far out as the cluster came. If all four sides were packed, then I found the bees clustered in the center of the hive in all directions. If this does not show the value of chaff packing, then I was wrong in allowing it to convince me that it were better to have my bees, all of them, in fully chaff-packed hives, as they are now. But, to return:

When these nine frames are filled with brood it is generally too early for swarms to issue to the best advantage for the production of honey; and desiring all the bees possible at this season of the year (these bees are in reality our crop of honey), I remove one of the chaff cushions from one of the five-inch spaces, and place three frames of brood, taken from the brood-chamber beyond the slotted ¼-inch division-board (which was placed there when I used side boxes, the bees passing through this slotted board to the boxes) when empty combs are placed in the brood-nest in place of the removed frames of brood. In a week the other end of the hive is served in the same way, which gives me, as will be seen, 15 frames in a hive, thus securing a large force of bees right at the commencement of the honey harvest, with little disposition to swarm thus far. As the brood in the frames set over in the five-inch spaces should be as nearly all sealed when set there as possible, it will be seen that, in 12 days, the brood from these combs should be all matured; and as the queen rarely goes into these spaces to deposit eggs, I have these combs empty of brood, or nearly so, by the time the wide frames of sections used on the lateral plan need to come out over these side apartments. They can now be taken out and reserved for new swarms, or used for tiering up for extracted honey. If any of the combs I wish to take out still have brood in them, they are just as good for the extracting super over a queen-excluder, or they can be used in forming nuclei or building up those already formed. As the frames are taken out, the chaff cushions are returned, they having been stored in the hive all the while, and the wide frames of sections allowed to go right on out over them, as I gave in my former article. When this hive swarms, the brood, with enough adhering bees to care for it, is set in a new hive on another stand. Six frames of comb foundation, or empty frames, as I think best according to the time of year, together with dummies to take the place of three frames, are set in the brood-chamber, and the swarm allowed to return, or hived back in the same hive (when the queen's wing is not clipped), when the work in the sections goes right along without interruption on account of the swarming. I need not enlarge on this matter. All will see at a glance that colonies treated as here given will far surpass in numbers, *at just the time we want numbers*, those kept in an eight-frame hive, and restrict the "mouths to feed" after the harvest is past, and yet give us sufficient bees for winter. What we want is a rousing colony at *just the right time*, and I know of no plan that will give such, equal to the contraction plan as outlined above. G. M. DOOLITTLE.

Borodino, N. Y., Mar. 16.

[You and friend Dayton are bound, I see, to put me in a hole. Now, may be I had better keep still, and, as Dr. Mason says, pull the hole in after me. No, I won't keep still. Friend

Dayton uses a twelve-frame L. hive, while you use a nine to fifteen frame Gallup hive with or without a five-inch packed space on each side. My remarks were confined principally to the eight-frame L. hive. You see the circumstances were a little different. If all had hives, and managed contraction as do you and friend Dayton, there would be no disputing your grounds. But for some reason or other, the *tendency* of the times is rather against contraction. Here at the Home of the Honey-bees it forced pollen into the sections, and caused the bees to build out and fill the sections only over the contracted brood-nest. The sections projecting over the brood-nest were hardly touched. If I did very much contraction I think I should prefer to do it *a la* Heddon, on the sectional brood-chamber plan.

Dr. Miller used to be an advocate of contraction; but now he has rather gone back on it. Perhaps he will tell us why. Hutchinson, in the *Review*, says, "With an eight-frame hive I have seldom found it advisable to contract the brood-nest of an established colony."

Yes, Dayton did make some good points in favor of contraction, and you score some more good ones; after all, the more I read your article, the more I am inclined to believe that I do not disagree with you very much as *you manage*. If my printed statements do not agree, it is because I have not made myself clear.] E. R.

[Friend D., I am greatly obliged to you for the heavy testimony you have given us in regard to chaff packing over an empty air-space. Perhaps your air-spaces were not air-tight; but when I devised the chaff hive I made a number of experiments very much like those you mention, to show the value of chaff. As you state it, it looks quite reasonable that your method gives a larger force of bees; but I confess I should have been better satisfied had you mentioned that you tried several hives without this plan of contraction you speak of.] A. I. R.

STRONG COLONIES FOR GOOD RESULTS.

PUTTING TWO COLONIES TOGETHER IN SPRING.

However bee-keepers may differ on other subjects, I think all are agreed on this. Last season was a poor one; and although my colonies were fairly strong, I thought I would make sure of having at least part of them give good results, so I doubled up a number. It was a very simple matter to double then, for my hives stand in pairs, each pair standing close side by side, and it was easy to take one away and move the other a little, so as to stand in the middle of the place where the pair stood. The returning bees from each hive seemed very little troubled by the change. The hives had eight frames, and none of the frames were taken away, but a second story given, one queen being taken away. The question may be asked as to what I should gain so long as I did not increase the number of workers. Well, suppose each hive would give a surplus of 10 lbs., and the two united would give 20 lbs., there would be only one colony instead of two to handle. Besides, there ought to be fewer unfinished sections.

Now for the results. I can not say for certain, but, judging from what other colonies did, I think I didn't get as much honey from these doubled-up colonies as I should have done if they had been left separate. "Why?" I don't know. That's one trouble with my bees—they have so little consideration for either my theories or my feelings. I had counted on making quite a splurge on reporting the considerable gain by my scheme, and it is no little humiliation to own up a failure. But the bees don't seem to care. Nearly always, when I plan something smart, the bees spoil it all. But I don't always tell about it. I don't like to. I've too much consideration for the feelings of other people.

Altogether, I had some 300 two-story affairs, at least part of the season, although most of them had only three or four frames in the low-story. A division-board was put beside these frames, and the empty space filled up with hay. To prevent comb-building between the two stories, a thin board was put in some cases, but generally a piece of cloth of some kind, perhaps an old bee-quilt. This allows no communication between the two stories, except a strip of one or two inches, the width of the hive, at the front or back end.

If the queen was left in the upper story, I'm not sure that she ever went down to the lower story of her own accord; but if she was left in the lower story, she was pretty sure to go up.

REARING COLONIES UNDER THE REGULAR BROOD-NEST, ETC.

By means of this two-story business I made a discovery of some value. Put a cloth or a board between the upper and lower story, leaving free communication between the two at front or back, having the queen in the upper story, and you may rely quite surely on having the bees start queen-cells in the lower story. It is much the same as Doolittle's plan of having queen-cells above a queen-excluder. By the way, if I'm not mistaken, the first public mention of having queens raised in an upper story with a laying queen below was made by me in the columns of Gleanings, and I think Doolittle refers to it in his book.

At first I was much elated with the idea of letting a young queen be raised to supersede the old one. But in this I succeeded, I think, in only a single instance. The young queen, in all other cases, was duly hatched, but disappeared before laying. If I were allowed to guess, I should say she got along all right till, in her wanderings, she got upstairs, when the bees killed her. It might be worth while to see what would be the outcome if an excluder were used so that the young queen could not get above. In Doolittle's experience, when the old and the young queens got together it was the old one that was killed. No matter whether the young queen was raised in an upper or lower story, she was the one to be killed with me. What made the difference? Could the bad season have had any thing to do with it?

Let me tell you the use I made of the discovery. It proved, in the first place, that a young queen can be raised in a hive with a laying queen, without the use of a queen-excluder. Such queen seems to be raised by the bees on the same principle as superseding, and may be expected to be of the best quality. If I wanted to save the queen I took her away just before or just after hatching. If I wanted to start a nucleus, all I had to do was to take away the lower story, bees and all, and set it in a new place. Enough bees would adhere to it to take care of the brood; and that brood, hatching out, would make quite a colony by the time the young queen commenced to lay.

Of course, taking the brood away in this way deprived the colony of the young bees it would have had later. If I wanted these younger bees to be left with the old colony, or, rather, if I wanted to return to the old colony all the field-bees of the nucleus, after the young queen began to lay, my plan was a little different. Instead of taking the lower story to a new place, I set it on top of the supers on the old place. Of course, there was no communication with the hive below; and after the young queen began laying I then set the nucleus in a new place, and all its flying force would unite with the old colony.

Here's a plan that might work for those who want increase but prefer to have no swarming. Just before there is danger of swarming, make the hive two-story, putting only one frame of brood in the upper story, and the rest in the lower story with a cloth between, leaving the queen in the upper story. In about twelve days, set the lower story in a new location. This latter will be so reduced in bees by the removal that I think it will not swarm, and the old colony will be left in nearly the same condition as if it had cast a swarm. But that's only my guess in the matter, and the bees would have to be consulted about it before the plan could be trusted. C. C. MILLER.

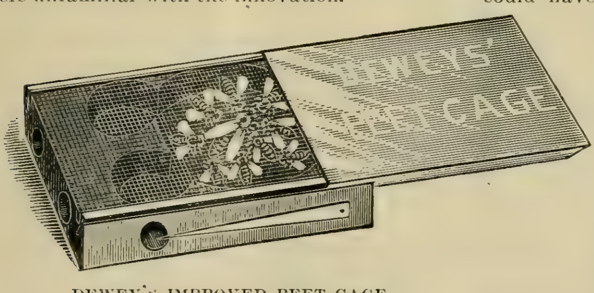
Marengo, Ill., Mar. 10.

[Friend M., we decided, about as you have, that uniting two colonies that are fairly started in spring, is, if any thing, a detriment in results. Of course, it is a good idea to unite two colonies so weak in numbers they would not pull through; but where they are fairly started, and have got things fixed to go right on when fruit-blossoms open, I do not believe it best to break up their arrangements, as we must do more or less to put two together. If one has more bees than he wants to care for, and no market for them, he might thus reduce his number of stocks, it is true.]

DEWEY'S PEET CAGE.

THE NEW SHIPPING AND INTRODUCING CAGE.

Mr. Root:—We hand you an electrotype for GLEANINGS, which you kindly offered to insert. If agreeable we would add a word to the readers unfamiliar with the innovation.



DEWEY'S IMPROVED PEET CAGE.

This is a standard Peet cage, save in having a wire-cloth slide beneath the tin slide, and three openings upon the edge into the candy. The original Peet cage is convenient in weight, shape, and size for the summer transport of queens. The objections upon different grounds made to it in GLEANINGS by Dr. Miller, Mr. Doolittle, and others, need not be repeated. It may be recalled how they demonstrated that time, combs, and queens, are too valuable to be devoted and sacrificed to the use of the Peet cage as originally devised.

The Peet idea of introduction, indeed, is obsolete; but the cage has advantages not inherent in the Benton, the Pratt, and other popular cages. There is the chief objection, that it has but one apartment. The new cage, as entitled above, has received this criticism, with the objection of extra cost; but it bears lightly these disparagements, trusting that time will show them both to be more or less immaterial.

The improved cage will drop between the combs, with very little spacing, into the midst of the bees, where its two gauze sides invite speedy acquaintanceship. What other cage has these two advantages—location in the cluster, and publicity of the queen? The time of liberation is dependent upon the number of passages uncorked to the outside bees. The Benton cage has but one opening, and is too thick to slide between the combs.

Will bees be shaken about more by transit in a shallow cage like the improved Peet, than in high-walled compartments of the other transmitters? There seems to be an answer upon theory. We will let experience give the verdict. Again, the bees are not in immediate contact with a chilling tin surface. Mr. P. H. Elwood suggests that wax applied to the inside of the slide in cold weather might tend to retain the warmth. This may be done, or a paper may be slipped between the tin and the gauze.

For those yet desirous of using an old and familiar method of introduction, the improved cage will be a Peet cage still by removing the gauze slide. On the other hand, when the tin slide is drawn away the queen may be introduced by almost any method now in vogue, and as soon, or as remotely as desired. All are free to use the cage. It has good points; do not sweepingly condemn it. The saving of queens in introduction will cover its extra cost, which is not large. The Falconer Manufacturing Co. are now making the cage. It will probably never come into universal use, but has a place to fill for a considerable class who desire at once a fair shipping and a reliable introducing cage. F. H. & E. H. DEWEY.

Westfield, Mass., Feb. 26.

[The cage as you have changed it is certainly improved; but it just occurs to us now, that, if you had gone just one step further, you could have improved it still more, and still have retained many of the features valuable in the original and new Peet cage; besides all this, it would cost less. Why have the tin slide at all? This, you remember, is one of the naughty features of the old Peet cage. The wood will shrink or swell so the slide will be either too loose or too tight. We would make the cage this way: The *wire-cloth* slide you have adopted is a good thing. Go a little further and make *two* wire-cloth slides, and groove both sides of the cages alike, and shove the wire-cloth slides, one on each side, into the grooves. Cover both sides with a light strip of wood ⅛ inch thick, and the size of the cage. These are to be held in place by nailing. The purchaser, on receiving his queen, simply pries off one of the wooden sides and then introduces by the candy or Peet method. If by the Peet method, he fastens the cage against the comb, in the regular way, and withdraws the wire cloth in place of the tin slide. Why, friend Dewey, you have given a suggestion that enables those who still like the old Peet method of introducing, and still do not like some of the disagreeable features of the Peet cage, to have just what they have been looking for, without most of the objections. Still, for all this we think the Benton cage is superior. *It is the one cage that has carried queens successfully by mail to Australia, back and forth to Europe, across continents, and to the islands of the sea.* One great reason for this is the three small compartments instead of the one large one.]
E. R.

WASH YE, MAKE YOU CLEAN.

THE NEW WATER CURE AT THE PRESENT TIME.

When I proposed sending our little pamphlets out by the thousand, as I did in our issue for March 1, I expected a flood of testimonials from a grateful people; but I confess I had no comprehension that we should get such astounding testimonials in regard to its power in curing disease and alleviating suffering as have been coming for the past few weeks. I have been saying to myself again and again, "This is a new thing, and it is fashionable. Everybody is talking about it, and we must make allowances for the effect of imagination." It is not very many years ago since people were buying electric medals, or buttons—yes, whole factories were engaged in making them. Even the hands in our establishment, in spite of all I could say, wore these senseless trinkets, and declared they felt stronger, had more vigor and energy, etc. I tried to remonstrate, and proved to them the device had no electricity about it at all—that electricity did not work in that way, etc. I finally gave it up in despair, and inwardly groaned in anguish to think that people of good sense should have faith in a silly trap that was just about on a par with nailing a horseshoe over your door for good luck. I do not know how long they stuck to their electric medals, but I think they are pretty much all gone now, and the electric belts and all such traps with them.

Now, the question that confronts us is, "What part of the wonderful cures that are told of in every mail, come from this same queer trait of humanity, and what comes from downright actual relief?" I am sure that a good deal comes from the latter; for it is as plain as an operation in surgery, or as plain as the remedying of a defect in a mechanical appliance; and along with the testimony comes a great string of facts in regard to relieving and saving the lives of *domestic animals* in the same way. For this purpose, any of the common fountain pumps to be found now in almost every household will answer an excellent purpose. One writer tells of finding a valuable ox just at the point of death, from a stoppage. He happened to know what could be done with water, so he borrowed a cheap pump of a neighbor, and the animal was relieved and on its feet in just a little while. I suppose that hundreds of valuable horses, cattle, and other stock are lost every little while just through ignorance of the simple means in the reach of every one to relieve them. You need not be afraid of using too much water.

As I expected, the question arises continually, "What shall be done with this large amount of water, to get it out of the way and avoid unpleasant smells and laborious carrying?" Very few bee-keepers' homes are provided with water-closet arrangements to dispose of this accumulation. The best arrangement I know of is one I have described before, which we have had in use for some years. The ground back of our outbuilding slopes downward for perhaps ten rods. Some years ago I dug a ditch, three or four feet deep and two or three feet wide, filling it within a foot of the top with stones, tinware, and any old rubbish I could pick up on the premises. Over the top I put flat stones, old tinware, sheet iron, and whatever else I could gather up; then it was covered with good rich soil. The covering was placed low enough so the plow would not disturb it. This is on the plan of father Cole's "new agriculture," as you may remember. The upper end of this covered ditch communicates with our out-building; but, please notice our whole ground is thoroughly underdrained, and the underdrains are just below this reservoir, so it can not stand full of water. Right over this covered ditch we have planted rhubarb, or pieplant; and it supplies our whole town with immense stalks of "pie timber" almost the year round. If anybody wishes to take exceptions to this way of raising garden-stuff, he is at liberty to do so; but I have never seen one who could tell a particle of difference between this product and that raised with an abundance of stable manure. In fact, there *is* no difference. Now, the above arrangement will dispose of just as much water as you feel inclined to use. The objection to Terry's plan of having heavy buckets of galvanized iron, is, that they soon become full, and heavy to carry away. One good friend suggests that Terry should modify his plans for an outbuilding, so as to accommodate the new water cure.

We have not space to mention a tenth part of the wonderful cures narrated; but I may speak of one or two. One friend was taken with a pain in the back while out in the woods chopping. He had great difficulty in getting home. The doctor was called, and he pronounced it rheumatism of the bowels. He did every thing he could for his patient, but it amounted to but very little. Other physicians and different medicines were used, but to no avail, and he and his friends began to think he would never be able to work any more. However, a thorough use of the new cure enabled him to get up and go to work in less than *three days*. His backache was the result of a stoppage that the water removed. It took nearly a month, however, to effect a permanent cure.

I must not fail to mention, that quite a number have testified to the effect that the new water cure has a wonderful effect in the modern disease called "grippe." Sudden acute attacks are driven away almost instantly by the use of hot water. One friend says that, by using daily, he entirely escaped a series of severe colds that affected the whole neighborhood around him.

Several have suggested having a short tube through the bottom of the pail, just large enough so the rubber tube will slip over it. Of course, there can be no objection to this plan, but it spoils the pail for other purposes, and I do not see that it is any more convenient. To facilitate using the water, I have a light tin pail, and the water is dipped from the hot-water reservoir that stands on our Stewart stove. This pail hangs on a hook right back of the stove. The rubber tube is on a little shelf (out of sight) right beside the aforesaid hook. This is simply dropped into the water, and a little bent wire near one end of the tube is slipped over the edge of the pail. As soon as the other end is dropped down the water begins to flow. The length of the rubber tube and the height of the pail determine the force of the jet of water.

DR. SALISBURY'S METHOD OF TREATING DISEASE, AND HIS USE OF HOT WATER.

Mr. Root:—In your article, "A New Method of Treating Disease Without Medicine," in Gleanings of March 1, there is a brief allusion to Dr. Salisbury's method, which is somewhat inaccurate. It is quite true, that the doctor has accomplished and is still accomplishing much for suffering humanity, but he doesn't *feed* his patients on hot water. In his system the hot water is used solely for flushing the stomach and intestines, cleansing the former from slimy, pasty growths, which interfere with good digestion, and the latter from feculent deposits. To feed his patients, the doctor prescribes beef—lean steak, free from fat and gristle, reduced to mince meat in a chopper, and then pressed into cakes or meat balls, and then broiled. According to Dr. Salisbury's theory, man is two-thirds carnivorous and one-third herbivorous; and his food should follow the same proportions. In some countries—India for example—the people, in the course of generations, have become herbivorous, and are able to live on a purely vegetable diet; but, few people can digest a purely vegetable or farinaceous diet in the United States. The doctor holds that most diseases are caused by a long course of eating improper foods which ferment in the stomach or bowels, and do not properly digest. His remedy is, first, to wash away offending and offensive matters by taking a pint or more of hot water at about a temperature of 110°, an hour before each meal, and the same interval before bedtime. Then he prescribes an exclusive meat diet, or as nearly exclusive as the patient can take it, forbidding sugary, starchy foods, and any thing prone to easy fermentation. Medicine is given, if necessary to help digestion. With good digestion the system begins to make good blood; and with a supply of good blood, all the organs of the body perform their functions well, and normal health is restored. This, of course, is not done in a day, for nature works slowly, and the result of a long course of wrong living can not be corrected by a short course of right living. In the case of serious diseases, like, for instance, consumption, it takes probably a year or two of treatment to get thoroughly well; but the improvement usually begins at once; and the end, if slow, is pretty certain.

The doctor's plan, you see, differs from the one you describe, in that it is more extensive—flushing the whole of the internal man, and not simply the colon, though the latter is good so far as it goes—and more natural.

It may interest some of your readers to know that Dr. Salisbury is an Ohio man, hailing, I believe, from Cleveland, though now living in New York, at 170 W. 59th St.

New York, March 7. E. CONNOLLY.

[My good friend, we are exceedingly glad to hear something which comes so near being direct from our old friend Dr. Salisbury. Perhaps I may remark, that I was at one time an enthusiastic patient of the doctor's—so much so, that, for eighteen weeks, I scarcely ate so much as a crumb of bread; therefore when anybody tells you that a man can not live on animal food alone you may know he is mistaken. At an early period of my life, for almost four years I ate only vegetable food. It were no more than fair, however, to say that I used plenty of milk and butter. I was at that time an ardent disciple of Fowler & Wells. In regard to animal or vegetable diet, my opinion is, that the great Father has given us a system so adapted to a variety of foods that nature can, without much effort, get along with either the one or the other; and I believe there are times, or special conditions of the system when either the one or the other almost exclusively may be a benefit; and I think one marked benefit I received in both cases was that I got so tired of my food that I was very certain not to overload the stomach; and I believe that almost every one who is ailing may receive benefit by eating sparingly. Find out, by careful experiment, just how much food is needed to enable you to get along comfortably, and then stop right square off when this limit is reached, always remembering that *too little* is far safer than *too much*. Hot water, taken in large quantities a full hour before meals, is many times an excellent thing. For myself, however, I greatly prefer it in the shape of hot lemonade. My good friend Dr. Salisbury, however, with most patients, would bid them omit the sugar part of the above beverage.

I beg pardon for my pleasantry in regard to feeding patients hot water; for if anybody knows that Dr. Salisbury chooses for his patients the most concentrated and hearty food there is to be found, *I* certainly ought to. Hot water of itself, without any other diet, would probably prove to be a rather "thin" food.]

INTERNAL BATHING—IS A CAUTION NEEDED?

Regarding your suggestions in regard to the use of water in cleansing the body internally, I should like to inquire whether, the use of water once adopted, it is not necessary to persist in it always thereafter. I have been told of cases in which defecation has not occurred for years without the use of water. H. M. WHEELOCK.

Fergus Falls, Minn., March 14.

[Friend W., two or three physicians have declared that there is danger in the way you indicate. I am inclined to think, however, that there can not be very much danger, for we have testimonies now from hundreds who have used it for from several months to several years; and I myself have used it daily for a week or two, and then stopped, and I did not experience any difficulty in the line you indicate.]

"THROW PHYSIC TO THE DOGS."

[I have several times felt that I should like to be able to cleanse the whole small intestines, in the same way we cleanse the colon. A good friend who has been for many years an invalid gives us a suggestion in this line in the communication below:]

In GLEANINGS for March 1st I notice a clear statement of the drugless remedy, and the benefits to be derived by its use. I have been a great sufferer from sick-headache, having it frequently, sometimes every week, and lasting three and four days, without intermission—one of the three or four days, often unfit for any business, or even to see a friend. My ailment was not like yours, Bro. Root—diarrhea, but the opposite—constipation—and of the most obstinate nature, so that pills and drugs of all kinds, thought to be helpful, were resorted to. I was also very careful as to the regimen of diet. These generally gave some temporary relief; but after a while, each in turn would, in a great measure, lose its power, until I had almost given up all hope of having any comfortable degree of health in this life.

When I heard of this "new method of treating disease without medicine" I gave it a thorough practical test. With me it did its work *well* just as you described, but did only *half* of the work. While the colon was cleansed, and apparently entirely relieved, the small intestines remained in their dormant and consequently diseased condition. I told our faithful family physician my difficulty, and it is for the sake of giving to any who have suffered as I have, the benefit of his reply that I now write this article.

Take a hearty drink of water, cold or warm (warm is best) on retiring at night. And as soon as you rise in the morning, use flaxseed (that which is not ground is best); pick all the straws or other refuse matter out of it, of course. Eat enough of it so that the bowels will have a free natural movement. It may take three tablespoonfuls—with others, much more, even to a pint a day. Be sure to take enough; it can not do any hurt. It will cleanse the stomach; and, as it passes the small intestines, will clear them; then, entering the colon, with the water treatment their united action will prove most effectual. The flaxseed leaves the whole system lubricated, so that the work of digestion goes on more perfectly—at least, this has been the result in my case. My bowels now move full and freely; and although I am 55 years of age, my general health is much improved. The headaches have almost entirely disappeared. As my ailment was of long standing, it is probable I shall have to keep up the use of flaxseed or the combined treatment for some time, or, perhaps, more or less through life. But if I shall receive as much benefit from them in the future as I have in the past, I can hardly say enough in their praise. L.

I have been using it for the past six weeks for what the doctor calls neuralgia of the bladder and bowels, and ulceration of the bowels. He gave me medicine to take internally, but I did not take it, as I wanted to test the hot water. I find I am perfectly free from pain, and am able to do my usual work. I used about three quarts every morning and night for the past month; since that the same quantity once a day. There are large numbers of people who have paid $4.00 for the cure, and they speak very highly of it; but they are bound not to divulge the secret, if it is a secret; but the public will owe you a debt that money can not pay.

Alvinston, Can., Mar. 14. James Orchard.

We notice in the *Canadian Bee Journal* of March 15, that the *Montreal Witness* has published the water-cure treatment exactly as given by Dr. Hall.

LADIES' DEPARTMENT.

BEE-KEEPING FOR WOMEN.

LIGHTER APPLIANCES FOR OUR LADY FRIENDS.

After reading the letter signed Emma Wilson, on page 80, I thought, why can we not have a corner to discuss gloves, aprons, etc.? There are lots of questions we women bee-keepers could ask of one another, while the men are discussing thick top-bars, closed ends, and dovetailed hives, with which they fill the paper, and I am not the least bit interested in, because the thing on my mind is section-cases for next season: what shall I get? One that will hold 24 sections, will with propolis and all complete, weigh 30 lbs.; this is too heavy for a woman to lift, especially when there are many and she is in a hurry. I have 32 hives, and have to do every thing around the bees myself; as they are so cross, none of the family will touch them. But if they are cross they are good workers. Last season they averaged 30 lbs. to the hive, while many others got nothing. Those "Blessed Bees" have been a success with me, for in the very poorest years I always get a little.

I have used the wide frames to hold sections, six of them holding 24 sections on the 8-frame Langstroth hive, but they are too heavy; so I took three of them and nailed on grooved strips and put in glass, or sometimes pieces of shingle or wood separators, and tied them together with cord. They are some trouble to fix, but when they are done they are very handy, as they are easy to lift and put on the hives, and they can be piled up two or three stories high, or turned around. I have thought if A. I. Root could see them he would say: "Oh dear! how very shiftless and untidy!" but I did it because it was easy to lift them. Mrs. W. Grubb.

Deansville, Deane Co., Wis., Mar. 2.

[Years ago we had what we called a Ladies' Department, but for some reason or other it was dropped. There is no reason why it could not be resumed *if* the sisters will be sure to write for it. Miss Wilson has already made a good start; and if the ladies will discuss some things all by themselves, we men will not stand in the way.

In regard to a suitable surplus arrangement, why wouldn't a dovetailed section-holder surplus case answer the purpose? Twenty-four pounds is too heavy to lift all at one time, you say. But, bless you, with the super as modified with a follower, you need not lift more than four sections at a time. Say, now, what is the use of lifting 24 lbs. so much, any way? If you don't want to bother with four sections at a time, just have a light, handy wheelbarrow close to the hive, and then sort o' tilt the case up on the barrow. You know you can handle a good many heavy things by simply getting the advantage of them in the right way, and still not be obliged to do any heavy lifting or straining. You remember years ago, Mrs. Jennie Culp used to produce some big crops of honey, and she used one of A. I. Root's handy wheelbarrows as her "best man" in the apiary. She made him (i. e., the wheelbarrow) do all the carrying, and managed the yard with profit and pleasure. "There, there, now," some of you will say, "just like all supply-dealers. They like to get in an advertisement of some of their implements in a foot-note." For conscience' sake! Can't we mention a good thing, even if we do sell it?] E. R. R.

GLOVES FOR BEE-KEEPERS.

RUBBER GLOVES, COTTON GLOVES, ETC.

Miss Emma Wilson wishes the experience of some of her bee-keeping sisters with regard to gloves in the bee-yard. In the beginning of our bee-keeping we tried rubber gloves, and promptly condemned them for reasons similar to those given by Mrs. Harrison.

Were it not that Miss Wilson expects to handle Italians instead of hybrids next summer, I should not think it worth while to bring to her notice the gloves we use, for they are by no means sting-proof. But with Italians the hands are in little danger, except such as proceeds from one's own carelessness. We use white cotton gloves, two or three buttoned, so that the wrists are protected, loose fitting, and with each finger cut off—and the edges stayed—just above the first finger-joint. To tell the truth, I find the unembarrassed use of my fingers so indispensible in handling frames and sections, that I dislike even this slight incumbrance, to which, nevertheless, I submit for the sake of some protection from propolis and a shade or two less of tan. The gloves are very cheap—fifteen or twenty cents per pair; and as they need frequent washing, half a dozen pair should be provided for a season. I wish Miss Wilson would try these with her gentle Italians next summer. I can assure her that they will prove more comfortable than buckskin, and, moreover, she will be able to place herself so completely *en rapport* with her bees that she need fear no stings except those that she may deserve. A pinched bee has a right to sting.

DO BEES DISTINGUISH COLORS IN A BEE-KEEPER'S CLOTHING?

I was interested in Miss Wilson's remark, that bees seldom if ever sting white. That bees have an eye for color, I learned in an interesting way a few summers since. On one side of the broad-brimmed hat I wore in the bee-yard, was a knot of cardinal ribbon; and I soon discovered that a certain colony of hybrids took it in high dudgeon if I approached too near. That ribbon was to them a red rag flaunted in their faces, and they rose up at once to resent the insult. Sometimes, when necessary to open the hive, I would make up my mind to quietly ignore them, for they never touched my hands nor tried to crawl beneath my veil. But to feel them hurling themselves like shot against the side of my hat, and to hear them siz-z-z-zing as they burrowed into that knot of ribbon, generally demoralized me to such an extent that I would close the hive and beat an ignominious retreat. I liked the bit of bright color on my hat, and was unwilling to part with it; so, in deference to their feelings, I pinned over it a piece of tissue paper. But a strong breeze would sometimes tear off the paper, or perchance release and expose only a corner of the ribbon, and at once the bees made me aware of the fact. So they conquered finally, and the objectionable color was removed. NELLY LINSWIK.

March 20.

[My good friend Nellie, you have given us some very valuable facts at a time when we wanted them, and I am glad of some suggestion in the way of something cheaper and better than rubber gloves. From what experience I have had, I believe that cheap cotton gloves, with the fingers cut off, as you suggest, will be the best and cheapest thing you can get. I have always felt sure that a good bee-keeper needs all the fingers God has given him, and he wants those so free and unobstructed that he may not only have all his fingers but all his wits at his fingers' ends. Your experience with that red ribbon seems to settle the matter; and now comes a question for our scientific friends: Why do bees object to red? It has been said, that our domestic animals recognize it as the color of blood; and the sight of blood infuriates not only animal kind, but even man in his savage state. We are told that the American Indians, at the sight of blood, often become raving maniacs, especially when their worst passions are stirred up by some quarrel among the tribes. But our little friends the bees have no red blood in their bodies. Why, then, should those colors arouse their ire and prompt them to sting? Will Prof. Cook come to our help?]

WOMAN'S DRESS IN THE APIARY.

BEE-VEILS, GLOVES, ETC.

This is to me an interesting subject, because I am always looking for improvements. But I have not been led to make much change in the dress I stumbled on when I began working among the bees. In making preparations I read all that my small stock (at that time) of bee-literature contained on the subject. My experience may help others.

From the A B C I got Mrs. Harrison's idea of a hat; but I have discarded that, except the cape, because I found that a straw hat, with not too wide a brim, is a better protection from the sun. I want the hat as light as possible, and not to press on or cover my forehead, and to have an air-space at the top. I like the cape to tie under the arms, and I generally fasten the hat on my head with a long hat-pin, or an elastic, because sometimes it will get disarranged just when I can not put my hands up to fix it. That was one objection to Mrs. Harrison's hat —it would slip about on the head.

For the dress, I wanted something to fasten at the neck over the cape. I had in the closet a linen duster, close-fitting, plainly gored, double-breasted, with two coat-like pockets. I put i on over the cape of my hat, and belted it at the waist. It covered my dress entirely; it was neat and tight, and the pockets were ever so handy. As it is linen the bees do not object to it, and it is light and cool. I have found it so exactly the thing, I have never changed; but when it was worn out I bought another, and last spring I went to every large drygoods house in Chicago for another, but they are no longer in stock. They use mohair now, and I was obliged to get the linen and make one. I have paid $2.00 for the ready-made garments, but this cost a little less.

For my hands, I have gloves, with gauntlets to fasten over the sleeves with elastics, sometimes; if very warm, only linen mittens made of the same material as my coat; and it is rare that I get a sting through them; but I want something on to keep my hands clean, and to prevent tanning. Some of my gloves have the ends of the fingers off. I use these when I want to work fast. I do not mind stings if they are not on my face.

When taking off honey I usually put on an apron to keep my dress clean; and, in fact, lately, more often I tie an apron around my waist instead of a belt. It answers the same purpose —to keep the bees from crawling up to my head; and, as I am so often on my knees when at work, it gets the grass-stains and dirt, and can be easily washed. Miss Wilson's apron is just the thing, because it is so snug. You do not want any thing that will blow about, and catch on hives and bushes.

As far as dress is concerned, I do not think a woman need to get any more stings than a man. In my armor I am almost sting-proof. It is an exception to have one on my body. I know I do not get the most stings in this apiary, unless I am the only one at work. S. M. STOW.

South Evanston, Ill., March 20.

SOME VALUABLE SUGGESTIONS IN REGARD TO WORKING AMONG BEES DURING VERY HOT WEATHER.

ALSO SOMETHING ABOUT REFRESHMENTS FOR THE BEE-KEEPER.

I see in GLEANINGS, March 15, that ladies are to have a department. I like a mixed session, as a general thing; but there are some subjects that we can profitably talk over among ourselves, that gentlemen have little or no special interest in. As bee-keepers, we need different clothing and far lighter implements. I'm not young, and far from strong; yet I can accomplish considerable by taking care of myself. I have to be careful and not get overheated; and I can not carry much weight in clothing, either. Our hives are so situated, that, during some time of day, they can be opened in the shade; but hiving swarms has to be done in the sun, many times with the thermometer one hundred in the shade. What clothing is best for me to wear may not be best or proper for another. I keep my clothing, that I wear to work in the apiary, in the honey-house, and go out there and remove my outside clothing, and hang it up, to put on again when I am through. During June, July, and August, in this locality I could not endure a ticking apron. My underclothing is the American costume, and is high in the neck, reaching from my ankles to my wrists; and if I have to hive bees when it is one hundred in the shade, I put on over this one skirt, a wet head cap, and then tie on my bee-hat, and put on a linen sacque, which keeps all bees from getting under the cape of the hat, and gloves with gauntlets. As soon as I am through with active work in the sun I wash, and change to warmer clothing, to keep from chilling.

I always have an umbrella at hand, attached to a staff, such as artists use, so I can stick it in the ground, to shade me when at work. When I hear, "Bees are swarming!" the first thing I get is the umbrella, to raise and shelter me while I am watching to see where they are going to cluster. With the staff resting upon the ground, it makes it easier to hold.

Heat may not affect all heads as it does mine; yet comfort and health should be considered before looks. If I worked at out-apiaries I should have to wear much warmer clothing, going and returning, than I could endure while at work.

It refreshes me very much, when I am hot, to eat a pint bowl of ice with a tablespoon, or a lemon cut up with the ice, and sugar. If I should drink a glass of ice-cold water it would make me sick; but the ice never does, melting slowly. MRS. L. HARRISON.

Peoria, Ill., Mar. 21.

[Now, dear friend, we are quite willing to submit, or, perhaps, to stay in some other department, when you are talking about clothing for women in the apiary; but when you wind up by talking about a pint bowl of ice, with lemons and sugar, to eat with a *spoon*, we want to be around with the sisters. Why, my good friend, you hit right squarely on my favorite beverage and luxury in the summer time. We have a great big ice-house of our own, chock full of ice from the carp-pond. Then we got a little machine, for about four or five dollars, that turns with a crank. Put in a piece of ice and set your pint bowl under the hopper; turn the crank and the ice is broken up in pieces about the size of peas. With a lemon-squeezer, put in lemon-juice and sugar to taste, then sit down in some quiet place to eat it with a spoon, just as you would mush and milk. I got the idea years ago from some of the health journals, that one could eat pounded ice where he could not stand a glass of ice water, and it has been worth ever so much to me. But to enjoy it, and have it do me real good, I want to take it slowly. And now here is a suggestion for poor unfortunates who at some time in their lives have been intemperate. I used to enjoy greatly (at least I thought I did) a glass of beer from a pitcher with a lump of ice in it; and a great many times old memories will come back and tantalize me; but after I have had my bowl of "lemon ice," as I call it, I would not give a fig for all the beer in the world. Now, if there are any among our readers who have found it hard work to give up the beer, let them try our plan. Mrs. H. and I do not propose to monopolize the idea, by any means. A good many times lemons and sugar are cheaper than high-priced fruit; and my opinion is, that they answer the purpose just about as well.]

RUBBER GLOVES.

NOT SUITED FOR BEE-WORK; MISS WILSON DISCUSSES CONVENIENCES FOR LADIES.

I have had so many good letters, and so much valuable information, in regard to gloves since my article on that subject, that I feel as if I should like to give at least a part of it to the readers of GLEANINGS. One and all agree that they want nothing to do with rubber gloves. Mr. Thomas, of Nebraska, gives five such good reasons for not using them that I will copy them.

1. They are not handy about getting on.

2. No matter how dry one's hands may be ordinarily, the perspiration will condense inside them, and the hands will be all the time wet.

3. They will almost always turn inside out in taking them off. In case they fail to turn, you must turn them to allow them to dry, and then they must be turned back again to wear.

4. They are tolerably expensive, and do not last long unless perfectly cared for.

5. (and biggest). The combined smell of rubber and perspiration, after the gloves have been used awhile, will leave one of the most horrible combinations in the shape of an odor clinging to one's hands that he ever experienced.

For two years Mr. Thomas has used a glove called sealskin. They are smooth and shiny on the outside, like kid, but somewhat heavier, white and pliable. He has never been stung through them. After some little difficulty I have succeeded in getting a pair, and mean to try them this summer.

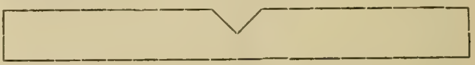
Mr. Coldwell, of Nebraska, has used dogskin, which he likes very much. Mr. R. McKnight, after experimenting a good deal, has decided to use kid. He also says that a cotton duck grain-bag, costing about 25 cents, makes a very good apron; and although a man, like a very sensible one he wears such an apron himself.

Mrs. Shreve, of Ohio, has used calfskin gloves, and likes them.

Although there is such a strong feeling against using gloves, it seems a good many can not get along without them.

As often said, it is the little things that make our work hard or easy. Having every thing convenient for our work is half the battle. Tools convenient, a good supply of smoker fuel in a handy place, etc., all make a big difference in our day's work. Every step saved is a help. I don't know of any one thing that is as great a comfort in the apiary as a good seat, light and strong—one that is easy to catch up when you are in a hurry. Use it whenever it's possible. That is my trouble—so many times I think I am in too big a hurry to stop to sit down, when I have no doubt I could save time by doing so. But I might as well confess I would not do it if Dr. Miller did not insist; and I am ashamed to say I sometimes feel fretted because he does insist, when I ought to know at the time that it is best. Although you may gain a few minutes at the time, not to stop to sit down, you become so tired that you will not accomplish as much in the course of the day.

Whenever we have any special work that will take some time to do, Dr. Miller will spend considerable time in planning how to make that work easier. For instance, if we are making shipping-cases he has a form to hold the pieces securely in place while we nail them; another form for making supers, etc. In glassing shipping-cases, unless you are very careful you will crack the glass. You want to drive the nail in just as deep as possible without breaking the glass; and it is a difficult matter to tell when that point is reached. Dr. Miller obviated the difficulty for me in a very simple manner. He took a piece of section, a little thicker than the glass, cut it the width of the glass, with a little notch where I wanted to drive the nail, something like this:



By pressing this against the glass I could drive my nail without fear, knowing that the hammer would strike the wood before the head of the nail could reach the glass. You don't know how much faster I could work by means of this simple arrangement. EMMA WILSON.

Marengo, Ill., Mar. 7.

[We are glad to get this testimony against rubber gloves; and it has been agreed so uniformly, that they are not suited for bee-work. There has been a protest in our catalogue all along, but still a good many customers buy them. Something cheap would be better; for when they get too badly worn or soiled they can be thrown away.

I always use a seat while working among the bees; but I don't want any thing to lug around all day, so I sit on the hive-covers, and I don't want any thing better. I will shortly illustrate how I manage.] E. R. R.

BEE-KEEPING AND HOUSEWORK.

SUNDRY ITEMS FROM MRS. AXTELL.

Women who make bee-keeping a business, as well as others, should learn how to make their housework light and easy. No work is more laborious than our washing. I have tried many ways of doing mine, and I find that a good washing-machine that covers up and keeps the suds hot is a great help; also borax dissolved in the water, a piece as large as a hickorynut, for a small washing, or a piece twice or three times as large for a large washing, with plenty of soap, will loosen the dirt and cause the clothes to be white and clean, and not injure the fabric. It causes flannels to be soft and clean. I buy borax by the pound, and use it in preference to any kind of washing-fluid or patent soaps.

SHORT VS. ABUNDANT STORES.

The talk about short winter stores being a saving seems very nice to the bee-keeper; but the bees are like a man with a pocketful of money—he is in better condition to take advantage of the times, and make more money, than one living from hand to mouth; and just so I think it is with the bees—they make us more money with their pockets filled; or, in other words, with plenty of honey at all times, when not able to gather it from the flowers. An old and experienced bee-keeper might be able to make more from his bees by keeping them with short stores at certain times of the year if he has plenty of time to be tinkering with them; but beginners would let them starve. They would be more likely to waste a pound to save a penny; and also those who have much other work to do had better not try to see how short of honey they can run their bees, or they will forget and run them overboard.

OUT-APIARIES.

Considerable has been written upon out-apiaries. The first object sought should be a good location, which generally is best near swampy or pasture lands; yet in this vicinity, where the most of the land is worked and planted to corn and oats, we often have rich fall crops of smartweed that comes up after the oats are harvested, and in thin places in the corn. The next object should be to plant the apiary in a permanent location where the man owns the property, and is not likely to move away; also, that the people are obliging, and likely to be patient with the bees. It is extremely unpleasant if the people are afraid of them, and all the time complaining of them.

SHADE, AND WHAT MRS. AXTELL RECOMMENDS.

I would not be so very much influenced by the matter of shade, as to where to plant my bees, if all things else were satisfactory; but I would secure it at once; and immediately, whether fall or spring, plant out quite thickly some fast-growing trees, such as soft or ash-leaved maples—some call them box-elders. I would not plant fruit-trees, even in a home apiary, as they are almost sure to be barked and killed, and are of too slow growth. I should plant the trees twice as thick as I wished them to be when grown. One will be surprised to see how much shade they will make, even the first season, if they are planted carefully, and, if dry weather sets in, are mulched. The large Russian sunflower will make a nice shade for the first season, if planted so as to throw its shade directly upon the apiary in the heat of the day. The only objection to it would be the large quantities of propolis it secretes. It is visited by the bees more for its propolis than honey, I think, and more by the common small wild bee than the honey-bee. One of our neighbors had his apiary thus shaded, and, when in bloom, it was quite picturesque. If the apiarist has any doubts of being able to secure a permanent place for the apiary, he should not build a house, but use empty hives to hold what articles need to be covered; or I would build a small house that could be easily moved by placing it upon a sled in winter time.

HOW TO MAKE THE WORK EASY FOR WOMEN.

But it is a great convenience, if a permanent location can be secured, to have two houses—one a small plastered one, with a window, a bee-escape, and a tight door, to keep all the honey and combs in, and another that a small stove can be set up in, where the apiarist can warm his coffee and dinner, and rest in cool days. It need be but a small room with only a pane of glass in the door, with no furniture but the stove and what can be made of the bee-fixtures; and yet it adds greatly to one's comfort. Such a room we have. When we go to our out-apiary to work we do not try to rush through the work so hard that our help will never want to go again, but we take along our reading, and rest awhile at dinner time, and either read or chat, and generally try to have a good dinner, so that our help often say they would rather go to the out-apiary to work than to work at home. Indeed, nearly all our girls (and I do myself) look forward to a trip to the out-apiary as a sort of picnic; then we try to get home so early in the evening as to be not too much fatigued for the next day's work. In the course of time we accomplish *more work* by not crowding our help or ourselves too much. If we push bee-work too hard, and the help gets vexed by the stings, it makes it more difficult to hire help to work with the bees; but if they have it rather easy, and a good time with the work, but still have the stings to endure, they will be more likely to excuse the stings, either in working with the bees at home or at out-apiaries.

HAMMOCKS, HITCHING-POSTS, ETC.

A hammock, too, is a great comfort to the apiarist, or, what I like better, a small bench with a raised head-board, that I can carry to any part of the apiary. A hammock swings too easily—one can not rise quickly from it to catch queens in swarming time; and in an out-apiary it tempts children to come there for a swing.

Last, but not least, should a good strong feed and hitching post be put up for the horses, under the shade of a tree if possible. If a feed-trough is just in front of the hitching-post they stand much more contented, and I know of nothing more annoying in connection with out-apiaries than to have the horses uneasy, and sometimes break away, and oblige one to leave the apiary with half a dozen or more bees following, to run to catch the horses. As Miss Wilson says, "It is the little things that help to make our work hard or easy."

Mrs. L. C. Axtell.

[I heartily indorse what you say in regard to these little conveniences in the apiary; and they make all the difference between hard and pleasant work. In regard to hitching-posts, I suspect that, if I had had a good one at our basswood yard, I should have saved the life of a valuable horse. But you remember that, contrary to what I knew was best, we were in the habit of hitching our horse to a young sapling; and you remember how he broke the thill and pushed the jagged end of it into his heart. For colts, at least, I would have a couple of posts and a cross-rail, so they can not catch the thill around the post and snap it in two. A feed-trough would be a good thing, and would help no little toward keeping horses quiet. I know how unpleasant it is to be working at an out-yard, and to be obliged to look every few minutes to see whether the horses are all right. And while we are talking about hitching-posts, I should prefer the side of a barn, with a ring in it about five or six feet from the ground. Not even a colt then can get its foot tangled or get into any trouble. I believe I would always hitch with a strong neck-strap, passing the strap through one of the rings of the bit. If a stray bee should happen to sting him then, there is much less danger that he will snap the strap or get into mischief. At our Shane yard we put our horse into a stable near at hand, after having taken him out of the thills. I tell you, it is no little comfort to know that a horse is safely stabled, and away from flies and bees, when working at an out-yard; and as this department is especially for ladies, it behooves the men to see that there are good hitching accommodations, and that all parts of the harness are secure. Never drive to an out-yard with a pair of poor thills. Whenever driving within the vicinity of bees, or drawing loads of honey, bees are inclined to follow, and, at best, accidents are liable to happen; so it behooves us to have every thing in good shape.] E. R.

OUR QUESTION-BOX,

With Replies from our best Authorities on Bees.

Question 181. 1. *In cellar wintering, how much ventilation do the hives need, and how would you secure it?* 2. *How much does the cellar need, and how would you secure it?*

I don't know. We winter all out of doors.
Wisconsin. S. W. E. France.

I would not bother with any ventilation at all. Keep your temperature up to 45° or 50°, and never mind the ventilation.
Michigan. S. W. James Heddon.

Raise the hives from the bottom-board two or more inches, paying no attention to the ventilation of the cellar, providing you can keep the temperature at from 42° to 45°.
New York. C. G. M. Doolittle.

No ventilation at the top, but all you can readily secure at the bottom. Usually, leaving the entrance wide open does very well; but to have the whole bottom off would be better.
Illinois. N. C. J. A. Green.

I ought to have more experience before answering. I should say, perch the whole hive up on two pieces of scantling. Where this is done I do not think the cellar needs any special ventilation.
Ohio. N. W. E. E. Hasty.

My best wintering was in a cellar in old box hives, inverted, standing entirely open, a hole four inches square at bottom of cellar, and the same at the top of the opposite side. These holes were covered so as to prevent strong winds from blowing in.
California. S. R. Wilkin.

1. Raise one inch from the bottom-board, with an inch block under each corner. I use loose bottom-boards. 2. Three-eighths-inch ventilators running through the roof, and one sub-earth, same size.
Wisconsin. S. W. S. I. Freeborn.

We remove the entrance-block, and sometimes the whole bottom-board. We also remove the cap and a corner of the quilt. We ventilate the cellar only by opening the windows occasionally.
Illinois. N. W. Dadant & Son.

There is no use in being too scientific in such matters. The exact amount of ventilation for hive or cellar would be only conjecture. Let the air in your repositories of bees be comfortable for yourself, and then you will be all right.
Ohio. S. W. C. F. Muth.

1. If the bottom-board is left on, leave the entrance open full width for ventilation. I winter with bottom-boards removed. 2. Enough to keep the air fairly pure. If I could I would secure it by means of a stove set in the cellar, the draft of which would be ventilation enough.
Ohio. N. W. A. B. Mason.

Leave the fly-entrance open. The cellar needs enough to keep the air pure, and we secure it with a sub-earth ventilator. Before this was put in, comb honey would become watery and burst the cells; but now it does not, and the air is as pure as in any room in the house.
Illinois. N. W. C. Mrs. L. Harrison.

1. I would remove the board cover, spread a piece of cloth (ducking) over the frames and cover with a cushion 3 or 4 inches thick, stuffed with fine hay or chaff, or dry planer-shavings, and give a very small entrance. 2. For a cellar 20x30x7, I would use a 5-inch ventilator connected with the kitchen or some other stovepipe.
Vermont. N. W. A. E. Manum.

I think the usual summer opening enough. If the hives are so made that they could be raised an inch or two from the bottom-board I should like it; then dead bees will not shut off the ventilation. I doubt whether it is necessary to ventilate the cellar. I do think it very important to keep the temperature of the cellar uniform, from 38° to 45° F.
Michigan. C. A. J. Cook.

1. That depends largely upon the cellar—its temperature, moisture, etc. We usually give 20 square inches or more at the bottom, as that in our hives is the most convenient point to ventilate. 2. With a small number of colonies, the natural ventilation in most cellars will be sufficient. By natural ventilation I mean that passing through the walls, crevices, etc. With a larger number of colonies, more ventilation must be given. For more particular information on this point I shall have to refer you to articles I have written on that subject.
New York. C. P. H. Elwood.

Give the hives abundant ventilation at the bottom. I secure it by placing the first row of hives on stringers, with the hives 6 inches apart; or, instead of the stringers, lay down hive-covers 6 inches apart, placing each hive over the space thus left. This gives a similar space between the hives, over which place the next tier of hives, and so on as high as you choose to pile them. This is for open-bottom hives. I should be at a loss to know how to secure the needed ventilation in a fixed-bottom hive. The cellar needs but little ventilation—very little, so long as the proper temperature can be maintained.

Ohio. N. W. H. R. Boardman.

I use the same rim mentioned in answer 180—500 cubic inches of air space, but with generous ventilators upon the sides, covered with wire cloth; a slot on each side 1x12 inches; the entrance is left open full size. I do not pay so much attention to cellar ventilation as formerly. I think the ordinary cellar will have plenty of means for the entrance of pure air. I believe a rapid change of air is detrimental to the bees. My rule is to test the air once a week with my nose. If sweet and healthful, the ventilation will take care of itself.

New York. E. Rambler.

1. None above, but all you can conveniently give below. For the sake of the bees, I'd like to have the bottom entirely open; but for my own convenience I like a deep bottom-board, leaving two inches of space under the bees, and the front entirely open. On one account this is better for the bees, for then they can be piled straight up, and jarring of one pile will not affect others. 2. More than some think it does. It needs enough so that it will seem fresh and sweet every time you go into it. In a windy time it needs no attention; but when still, if warm enough I'd open doors and windows. A sub-ventilator helps, and a pipe opening into a chimney is about absolutely necessary. A low fire in a stove when weather is not too warm, gets up ventilation.

Illinois. N. C. C. Miller.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

WAX QUESTION REVIVED AGAIN; HOW MANY POUNDS OF HONEY TO ONE POUND OF WAX?

Seeing so much in the bee-journals about how much honey it takes to make a pound of comb, I can not overlook all these articles without saying something relative to my experience. I rather cling to the old tradition of 20 pounds of honey to make one of comb. Now for my reasons: In the summer of 1878 I found an after-swarm of bees on a limb of a small tree. It was the 8th of July when I got them. I put them in a raisin-box which I found. As I knew nothing about bees, I thought it would do all right. This raisin-box was 14 inches long, 10 wide, 8 deep. Now, you see this was a small hive. I did nothing more with them till September, when a friend of mine, who understood bees, came to see me. He took the box up and looked at them closely. He said they would need feeding. The box was about a third full of comb, but not much honey, so I began feeding sugar. I fed $5 worth of sugar, or 50 lbs. The water that was added to this would make it over 60 lbs. Now comes the test. When I began this feeding, the honey season was all over. The hive was only a third full of comb, very little honey in it. Now, when I got through feeding this amount, the hive was filled with comb to the bottom; and when I carried them into winter quarters the hive, bees, syrup and all, weighed 20 lbs. Now, I should like to know what became of all this syrup if they did not use a lot of it for comb-building. Suppose the bees used 25 lbs. of this syrup for brood-rearing, and 15 lbs. for winter stores. You see how much would be left. I have been keeping bees ever since I got this hive, and I have had good success. Some years I have had tons of honey.

Birr, Ont., Jan. 26. Wm. Coleman.

[Your raisin-box, if we figure rightly, would contain about 2 pounds of comb; hence the bees must have built, after feeding, 1⅓ lbs. If there were 15 lbs. of stores, and the bees consumed 25 in brood-rearing (they probably did not consume so much), there would be 20 lbs. left for comb-building, or 15 lbs. of honey to a pound of wax. As the bees probably did not consume so much in brood-rearing, the proportion in this case would come pretty near that of the "venerable falsehood," as it has been called; but it should be said, that there are many more reports of experiments in this line that make the proportion all the way from 1 to 3, to 1 to 15. The general average has been perhaps one of wax to ten of honey. It has been shown that pollen makes considerable difference in results. You do not say so, but we judge that at the time you fed your bees they were not gathering much pollen, though it is evident they must have had some for brood-rearing. If you were to repeat the experiment at a time of year when there is an abundance of pollen, using honey instead of sugar syrup, you might see a difference in results.]

THE PER CENT OF WAX OBTAINED BY A SOLAR WAX-EXTRACTOR.

I made a solar wax-extractor last summer, and extracted all my wax nicely; but toward the end of the summer I discovered that only about 60 or 70 per cent was extracted. I boiled a lot (half a market-basketful) of refuse, and it yielded almost a pound of second-grade wax; but I had to squeeze it by hand through a cloth, and then boil it in water to collect it and wash it. Honey is up high now, 15 and 25 cts.

Mr. Doolittle measured to get the distance between combs in some box hives he had; but he says that he measured the marks where the comb was built on to the top-board, and found the distance was $\frac{5}{16}$ inch between the combs. I bought some comb in old-fashioned box hives from a neighbor last summer, and measured on the top-board and *in the brood-nest*, and I found that the distance varied from ¼ to ½ inch all over. They do not always build straight unless the one next to it is straight.

Geo. E. Fradenburg.

Kansas City, Mo., Jan. 18.

[Your observation agrees with ours.]

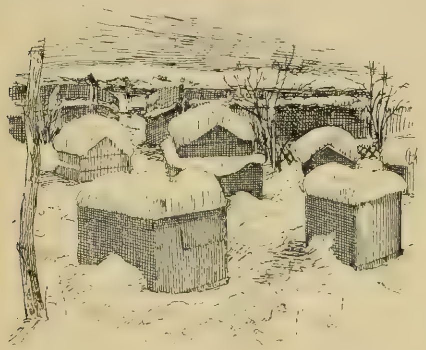
ESPARCETTE; ANOTHER PROMISING HONEY-PLANT.

I wish to call the attention of all bee-keepers to what I believe is destined to be the most valuable honey-plant known in the irrigated district. It is the forage-plant called esparcette, or sanfoin, and described in the catalogue of F. Barteldes & Co., Lawrence, Kan., page 76, as belonging to the same family as alfalfa, and well adapted to light chalky soils, sands, gravels, and barren regions, where rainfall is not plentiful and irrigation is not obtainable. It is a perennial, with hard woody roots; but I am told by those who are acquainted with it, that it can be plowed under. And now for its honey virtues. A small piece is under cultivation at the Government experimental farm near my apiary (about three-fourths of a mile); and while in bloom it was more thickly covered with bees than any other blossoms I have ever seen. This was at a time when they could get nectar from other blossoms, such as apples, a little white clover, etc. As it is mentioned in Gleanings as a valuable honey-plant in England, and grown there for hay, I think it would be valuable in the Eastern States, especially on lands where other grasses do not succeed. Mr. S. Simmins, of England, mentions the plant in Gleanings, Vol. X., page 499. It would take up too much space here to mention all the good things said about this plant. I hope to hear from others in regard to its adaptability to heavy soils under irrigation. J. B. Colton.

Garden City, Kan., March 5.

RAMBLER'S OUTSIDE WINTER CASES; YELLOW OIL CLOTH INSTEAD OF WOOD FOR OUTSIDE CASES.

Herewith find photo of the hive winter cases I described to you.



In November I prepared two Heddon hives, each hive with two cases and a three-inch rim under the cases. I then covered all with several thicknesses of newspapers, and put over them a hood of yellow oil cloth. This oil cloth is of the same material that oil-cloth coats are made from, and is called "fish brand," as it is prepared with some kind of fish-oil. Coats made from this material will turn water much better than an ordinary rubber coat, and do not crack in cold weather. These two colonies are in splendid condition, though the weather has been quite severe. I give them the entire entrance. This oil cloth can be prepared by the bee-keeper by getting the fish-oil from the manufacturers. I think this is not a new idea, for it has been in use in some apiaries for some time, only upon a different packing. The cost of the oil-cloth case, as I purchased it all prepared, is about 25 to 30 cts., or 20 cts. if made by the bee-keeper. Rambler.

[Won't those oil-cloth cases or sacks, after several seasons, get rotten and torn? They are cheap, I know.] E. R.

PAINTED CLOTH INSTEAD OF TIN FOR HIVES.

Friend Root:—You inquire in Gleanings, "Who has had lots of experience in cotton roofs for hives?" My experience is somewhat limited, as I purchase my hives and use the covers as manufactured; but I have one chaff hive, made as per A B C, on which, having no new cloth handy, I used an old piece of black calico painted with two coats of white paint. It has stood out six years; and although the paint is all worn off it has never leaked a drop, and the bees have occupied it the whole time, it being the only colony I have not been obliged to feed to keep alive. My experience justifies the assertion that I would rather have cotton cloth *painted* than either tin or wood. It is lighter and warmer than tin, and never shrinks or swells, like wood. In Florida, the second floor of two-story verandas are frequently covered with 8 or 10 oz. duck, and painted, giving much better satisfaction than wood, as it keeps water out of the joints, prevents decay, and wears longer than flooring if kept painted.

Pecatonica, Ill., Jan. 20. G. D. Rodgers.

[Thanks. These are just the facts we are after. Whom shall we hear from next?]

A GLIMPSE FROM FLORIDA; HONEY AND ORANGES FROM THE SAME TREE AT THE SAME TIME.

Mr. Root:—Can you gather two crops off the same tree at the same time? We are doing it to-day. While we gathered the oranges, the bees were much more busy gathering the honey from the flowers. Two friends, one from Minnesota, the other from New Hampshire, helped us, just for the fun of it; and didn't they eat oranges! The trees are quite full of bloom, and the bees are just booming. They were so intent in getting the sweets that they let us knock them around pretty roughly. Prospects for a big crop are good. This time last year our bees were starving, but now they have lots of full honey, and are storing now more honey than I ever knew so early in the year.

W. J. Drumwright.

Sarasota, Fla., March 3.

CASSAVA—A NEW SOURCE OF HONEY.

send you a specimen of cassava honey. As you are aware, cassava is grown as far north as middle Mississippi for the root, which is an excellent food for man and beast, which latter includes hogs, cows, sheep, chickens, etc. From it is made an excellent starch, and tapioca is also a product. I had quite a patch, and my bees boomed on it almost like buckwheat. It is in bloom from September till frost, or Jan. 1, at least. I have never seen it mentioned as a honey-plant, and I think there can be no mistake as to the source from which it was obtained.

Irving Keck.

Bowling Green, Fla., March 14.

[Friend K., I believe you have the credit of being the first one to mention honey from the cassava, and we have no doubt that you are right about it. If we can find plants that produce a regular article of commerce, like tapioca, we shall be getting ahead some. Will other readers of Gleanings who live where this plant is in cultivation, please give us their experience? Perhaps we had better commence using tapioca more largely, that there may be a greater acreage of the plant grown. The sample of honey is very fair, though a little off in color, and having a faint taste that would suggest honey from the vicinity of the tropics. Altogether, however, I think it would compare favorably with honey from palmetto and other similar sources.]

BOARDMAN'S SOLAR WAX-EXTRACTOR; A CORRECTION.

In regard to the solar wax-extractor and honey-evaporator, described in Gleanings of Jan. 15, make as many as you please. I do not propose to go into the supply-business, and shall at most make but a few of the extractors, in an experimental way.

I noticed in the description two rather misleading errors. On page 50, second column, 6th line from the top, the description reads, "The lower end of the extractor is covered." It should read, "*cornered*." The corner is taken off. Again, near the end of the description it reads, "painted a drab color." It should read, "*a dark color*." H. R. Boardman.

East Townsend, O., Feb. 2.

HOW TO GET RID OF A FERTILE WORKER; AN EASY WAY.

I for one like to have GLEANINGS sent after the time paid for expires. I noticed in GLEANINGS for Dec. 15, one writer (C. C. Miller, I think) tells how to get rid of fertile workers. I read of a way in the *Api.*, I think, which I tried last summer. No doubt you "old fellows" know *all* about it, but it is an easy way for a beginner. Set the hive with the fertile worker on top of one of the strongest colonies you have. My strong colony had a case of sections on, which I took off and put on top of the now two-story hive. I left them there about four weeks. I had a good deal of trouble in handling this double colony, not because the bees were cross, but because there were so many of them. They just *boiled* over whenever the hive was opened. When I separated them the queen was with the top hive. The lower hive started 14 queen-cells. I cut out all but two, and in a few days one of these, and I soon had a laying queen. Both colonies were in good condition for wintering with a little surplus. JOSEPH F. BARTON.

Chicago, Jan. 1.

CLOSED-END FRAMES HANGING FROM THE CENTER.

I use a closed-end frame that hangs from the center, on tin rabbets on the ends of the hive. This frame is cheap to make, and I think it is perhaps easier to handle than some. It is really a hanging frame, and is also a very simple reversible one as it rests (or hangs) from the center. Hanging, as it does, from the center, on tin rabbets, out of the way of the bees, they do not stick them down much if any, so you can slide a body of these frames apart and ascertain the condition of the center of your colony without disturbing them much. I have used this style of frame two seasons. At first I thought they might be more objected to in handling than a swinging or loose frame; but now I find I can get at what I want to ascertain at the center of a colony, in much less time than with any other frame I have ever used. I think there isn't any gain in handling a brood-chamber over too often; and for many advantages, I think the closed-end frames will be of common use. W. H. NORTON.

Skowhegan, Me.

ANOTHER SWARM THAT LIVED AND PROSPERED IN THE OPEN AIR.

Did you ever know or hear of a swarm of bees building their comb in the open air, in the limbs of a tree, in this country? I believe they do in tropical countries. In going through my pear orchard in November, after the leaves had fallen, I saw what I took to be a hornet's nest; but on examination I found it was a large bunch of comb, built by a swarm of bees. I got a ladder, and took it down. It is quite a curiosity, and I think it ought to be preserved. If you would like to have it to show to your visiting friends, I will send it to you. W. W. YOUNG.

Worthington, Ky., Dec. 18.

[Bees don't very often build combs in the open air, but we get reports of it from time to time, but more particularly from California. The comb might be a curiosity for the World's Columbian Fair. Dr. Mason, can't you use it? If so, give our friend instructions how and where to send it.]

IS IT CHEAPER TO RAISE BEES BY THE POUND THAN TO BUY THEM?

What will it cost to raise, say, 100 lbs. of bees by feeding sugar to the required number of hives, supposing the weather warm, plenty of pollen to be gathered within a short distance, but no honey, or too little of it to be considered? Or is it cheaper to buy than to raise them by the pound?

Knoxville, Tenn. ADRIAN GETAZ.

[It is cheaper to raise the bees by feeding, usually, than to buy; just how much, we can not tell. A good deal depends upon locality as to the price of bees. In a good many places, bees that are blacks and hybrids can be bought for a mere song after a poor honey season.]

QUESTIONS REGARDING FIXED FRAMES.

1. In adopting the fixed distance with closed-end-bar frame, will it interfere with the interchanging of frames throughout the apiary? 2. Is it possible to get combs built so true and straight that they may be used *anywhere* and in *any* hive, without pinching bees, or *vice versa*—widening the fixed distance between combs? 3. Will it be practicable at all times to clamp the frames tight together with follower and wedge? I should like very much to hear the opinion of the Solons. E. S. BROOKS.

Silverton, Or., Jan. 21.

[1. There is no trouble about interchanging frames for fixed distances; at least, bee-keepers who own colonies by the 500 seem to experience no trouble.

2. Yes, sir. That is just the way to get combs straight and true, by having fixed distances.

3. There will be no trouble if your hive is made right. If the Solons of fixed distances disagree with the answers made above, will they please correct?]

SAWDUST IN PLACE OF CHAFF, ETC.

1. Is sawdust good packing for chaff hives? 2. Is the Gallup hive as good or better than the Langstroth? 3. I have a large underground basement under the barn. Would it be a good place to winter bees in one end, and have stock in the other, by taking up the floor where the bees are? It is a stone-wall basement, well ventilated. It hardly ever freezes in it.

LEWIS LEIT.

Mayville, Tuscola Co., Mich.

[1. Yes, nearly as good, only it makes hives too heavy. Wheat chaff is the lightest of packings unless we except dried leaves. 2. There is no difference—at least, reports show none. It is not so much the frame as the bee-keeper, and the *protection* he gives the bees. 3. We should think so.]

MANUM'S WINTERING.

My bees had their first fly this season March 11. I opened them up in two apiaries, and found them in good condition. They appear to have wintered well. We Vermonters are very hopeful that the coming season will be a good one—at least, the prospects are good.

Bristol, Vt., March 17. A. E. MANUM.

A CAUTION IN THE USE OF SULPHURIC ACID.

Why did you not caution the friends about the danger of putting sulphuric acid into hot water when commenting on F. A. Salisbury's article, on page 121? I call your attention to this, lest some one should lose an eye, or be badly injured otherwise. J. S. HUGHES.

Mt. Zion, Ill., Feb. 19.

[There have been a great many accidents with sulphuric acid; but, used as given in GLEANINGS, we think nothing serious will follow.]

HOFFMAN FRAMES QUEEN-EXCLUDING.

Friend Root:—I am making an improved Hoffman brood-frame. I am cutting out on each side of the top-bar scant $\frac{3}{32}$ of an inch, which leaves about $\frac{5}{32}$, which I think will make them queen-excluding. I will try two or three hives with these frames next season, if I live. I should like to have some one else try this kind of brood-frame, and report through Gleanings. **H. Mansperger.**

Lewistown, Mo., Jan. 26.

[You will hardly be able to make Hoffman frames queen-excluding in the way you suggest. Propolis will accumulate between the edges so as to widen the spaces. You may be able at first, with good workmanship, to make it work.]

GLUE FOR LABELING TIN—ONE THAT GIVES PERFECT SATISFACTION.

As I was unable, during the busy season, to "keep up with the times," I have been reading up Gleanings more thoroughly during the winter months. I see in April 15th No., 1890, your inquiry for a better plan for fastening labels to tin. Here is a recipe for a glue that has worked perfectly. I have used it five or six years, and have never known a label to get loose when properly applied with it. It was given me by my friend D. E. Brubaker, now of Mt. Morris, Ill., while visiting me in 1886. He says it has given him entire satisfaction for ten years:

Stir 2 oz. pulverized borax into 1 qt. boiling water. When dissolved, add 4 oz. gum shellac. Stir while it boils, until all is dissolved. Apply with a brush in the usual way.

I prefer using a little less water, especially if the labels are small and stiff; then if it gets too thick to apply readily, warm it a little or add a little hot water. After applying the label I press a damp cloth over it to press out and wipe off any surplus glue that may come to the edge.

Mt. Vernon, Ia., Feb. 14. **Oliver Foster.**

[The following is what Mr. Brubaker himself says regarding it, in answer to a letter from Mr. Foster:]

Oliver Foster—Dear Sir:—In reply to your inquiry as to whether I would have any objections to your giving the readers of Gleanings my recipe for gluing on labels, I will say, most assuredly, I have none, and I feel that the readers of that excellent paper are entitled to it. I have found the preparation to give entire satisfaction for the past ten years. From my experience you can recommend it with entire confidence. **D. E. Brubaker.**

Mt. Morris, Ill., Feb. 11.

[We tried a sample of the glue sent by Mr. Foster, made according to the directions above. It makes the labels stick with a firm grip on tin, and is, perhaps, the best of any thing ever given. We have long wanted some suitable glue that would answer the purpose. Almost any thing will stick labels to glass; but when it comes to tin it is another thing.]

DO BEES PROGNOSTICATE?

I will mention, in confirmation of your suggestion, that bees do not prognosticate the coming season, but are influenced only by present conditions. About 32 years since, I lived in Guernsey Co., O., and kept bees. I think it was the 4th of June, 1859, we had a hard freeze, killing the corn. The wheat that was headed out, and all the clover that was in bloom, was killed, together with almost all other bloom. The bees had had many drones, and were ready to swarm. Within three or four days after this, the bees had killed all their drones, even destroying the drone larvæ. But soon after, bloom again became abundant, the bees reared a new set of drones, and swarmed as usual.

Ventura, Cal., Feb. 10. **R. Wilkin.**

WHITEWASH AGAIN, FOR HIVES.

I see on page 51, in your foot-notes to William G. Hewes, you speak of whitewash for hives. I would say that, to make whitewash for hives, use whiting and glue, about ¼ lb. glue to a common pail of whitewash. It will not crack off, nor soil one's clothes, and will last much better than lime. It is also good for filling old buildings preparatory to painting. It should be used hot. **John Burr.**

Braceville, Ill., Jan. 25.

[We have used glue considerably for whitewashing the inside of our buildings, but we were informed by our "boss mason" that glue would not answer for outdoor exposure—that grease or oil would have to be used instead.]

CLEAN GRAHAM FLOUR.

Buy the wheat just as soon as thrashed, and before it is put into a dirty bin and run over by the rats and mice; then look it over by putting a gallon or so into a large pan, and pick out the bits of straws and hulls, and grind it on a small machine attached to a horse-power or windmill. Mr. Axtell has one attached to his horse-power. We can grind it very fine by grinding it twice, or it may be ground very coarse, and used as cracked wheat. If boiled until tender, and eaten with honey and new milk or cream, it is delicious and very healthful, especially to one troubled with indigestion.

A good many told me, during the past year, they could not get good graham flour since the roller process came into use for making white flour, and that the graham they now get seemed more like poor white flour mixed with bran, which can not be nearly so healthful as to get good wheat and make our own flour, which makes very sweet bread.

As it is difficult to get an oven hot enough to bake graham gems made of only flour and water, so as to be light, I usually make my graham bread with yeast, as I do other light bread, first setting the sponge of white flour, and, when light, mix with graham flour. Mix just as stiff as can be stirred with an iron spoon, or just as soft as a loaf can be formed with the hands, and place in pans to bake, or let it stand to rise once after putting in the graham flour. In that case a little soda should be added, as graham bread sours more quickly than white. It also rises more quickly, and should be kept cooler while rising, if intended to be baked at the same time as the white bread.

HOW TO COOK EGGS.

Not until a few weeks ago did I learn how to cook eggs so as to be healthful, so that the white will be thickened like starch, but not be hard and leathery, and at the same time the yolk will be set also. Put fresh eggs into a cup or kettle of cold water, and let it stand on the stove till they come to a boil; then remove immediately. If the stove was not too hot or too cold you will find them cooked very nicely.

Roseville, Ill. **Mrs. L. C. Axtell.**

SPRAYING FRUIT-TREES.

I want to spray my pear, cherry, and plum trees, when in blossom, with Paris green. My bee-stands are all about them. Will the poison affect the bees or honey? **A. T. White.**

Antioch, Ill., Feb. 5.

[Spray your trees just after the blossoms have fallen off—earlier or later will do but little good to the trees. After the blossoms are gone, of course the bees will not visit the trees, and no harm will result.]

SPECIAL DEPARTMENT FOR A. I. ROOT, AND HIS FRIENDS WHO LOVE TO RAISE CROPS.

A WONDERFUL AND STARTLING DISCOVERY, EMANATING FROM OUR EXPERIMENT STATIONS.

Just now we have something that seems indeed too good to be true. I do not know who first suggested the idea, but our Ohio Bulletin gives the credit of the experiment to the Cornell University, at Ithaca, N. Y. Like many other great strides, it seems that several of the Experiment Stations have had a hand in it. For some time back, reports have shown that varieties of strawberries that do not bear pollen have grown greater crops and larger berries than the perfect (or pollen-bearing) varieties; and it was suggested that this was due to the fact that it requires much of the energy and strength of the plant to perfect the pollen. Recently our Ohio Station discovered that asparagus-plants are both pollen-bearing and non-pollen-bearing, or male and female; and that, if we select only the male plants, or those that produce no blossoms or berries, we shall get much stronger shoots. And now Cornell comes in and tells us that we may cut the tassels from every other row of corn in our cornfields; and that those stalks or hills not allowed to bear tassels will give—what do you suppose? Why, not only larger and better corn, but *50 per cent more* in quantity. In the experiments, the tassel was snapped off just as soon as it could be done handily, and the field was gone over three times. In the Bulletin, a full record is made of the experiments. That there might be no mistake in the conclusions reached, "the aggregate results of 24 distinct duplicate experiments" were taken, "each of which alone showed the same thing as the aggregate of all." If this is really true, it bids fair to be one of the greatest achievements the world has ever known in agricultural science; and, of course, the same thing, or something similar, may be applied to all plants that bear pollen on one plant and fruit on another. In order to test it early we have planted some corn in our hot-bed across the way; and just as soon as the tassel is visible, "amputation" is to be commenced. Of course, enough pollen-bearing stalks must be in the vicinity to insure perfect fertilization. The success of the experiments is based on the fact that nature furnishes a great surplus of pollen, as plants are ordinarily grown and closely cropped on our fields. A parallel case is the restriction of drone production in our bee-hives. In their native state it is quite important that every hive should rear many thousands of drones; but what would be thought of the apiarist nowadays who would permit drones to mature and issue by the thousands in every hive of an apiary of 100 colonies or more? One hive in a hundred could nearly if not quite rear drones for them all; and the wonderful fact that confronts us now is, that possibly one stalk of corn can furnish pollen-dust enough for not only two, six, a dozen, but may be *twenty* stalks of corn. Who knows? And is it not possible, dear friends, that farming *is* going to pay after all, when we just get the *hang* of things, and get acquainted with old Dame Nature?

DO COMMERCIAL FERTILIZERS PAY?

In the report on corn of the Ohio Experiment Station for February, 1891, we find the following:

> No practical benefit was received from the use of commercial fertilizers. The increased yields from the use of stable manure probably repaid the cost of the application, and left some profit.

Now, friends, this is serious business. Farmers are complaining bitterly already that their crops do not pay cost. If in addition to this they are paying out their hard earnings for commercial fertilizers that don't pay, it is a fearful thing to contemplate. The trouble seems to be, that so many experiments are made without testing alternate rows with no fertilizers. The use of phosphate on rye and buckwheat, on our own grounds, pays, without question. But I have never been able to demonstrate to my satisfaction that any of the chemical fertilizers do any good whatever on sweet corn and most other market-garden crops. Stable manure, guano, ashes, and, in some cases, lime, produce marked results. But I have for years been coming to the conclusion that it paid us to put our money into stable manure; and for vegetable-plants in our plant-beds, guano often pays, unquestionably. Lime or ashes used with guano, or with stable manure, often make it act more promptly. The lime also destroys insects, and, where used in sufficient quantities, it destroys angleworms by the thousands. Now then: Before you invest very much money in any commercial fertilizers, experiment by putting the fertilizer on strips clear through your fields. After you have shown conclusively, by experimenting in this way, that it is worth what it costs, then invest, and not before. Two or three years ago I saw so much said in the papers about the nitrate of soda that I got a bagful. As we had a very pretty lawn in front of the house I thought I would astonish the family and the neighbors by showing them what it would do. So I marked out the letters on the lawn, "A. I. R." Then I sprinkled nitrate of soda along the letters. As I did not know just how much to put on, I put it very heavily on some letters, and lighter on others, and watched anxiously for the extra growth and color where the nitrate was put. Well, the lawn got to be very nice and green all over; but during the whole summer I saw nothing that enabled me to detect a particle of difference in the growth or color of the grass where the nitrate was put on the letters. Then I tried the nitrate on other things; but at the present writing I have never found it to produce any benefit perceptible to the eye or to other tests, except on a crop of spinach. Just now I have been testing it on spinach in the greenhouse; but even there no one can see a particle of difference where the nitrate was put.

Since writing the above I have been reading what "Joseph" has to say in the *Farm and Fireside* about the use of nitrate of soda. Here is a short extract:

> I have repeatedly spoken of the really wonderful effects often noticed from the use of nitrate of soda. I shall never fail to use it largely on spinach, onions, cabbage, celery-plants, etc., hereafter.

Other writers have spoken of it in the same way. Now, there is something about this that troubles me. I wonder whether it is possible that our poor success is on account of the heavy rains we have been having for two or three seasons back. Joseph speaks in the same article of their severe and long-continued drouth. Is it possible that nitrate of soda would overcome to some extent a lack of moisture? Can't our experiment stations explain these wonderful differences in results?

SOME HINTS FOR SOWING CELERY AND OTHER SMALL SEEDS.

Cultivate your flower-garden;
  All weeds and thorns subdue;
Negligence is hard to pardon,
  And always will be charged *to you*.

Localities differ. This should always be borne in mind. For instance, when celery is sown in the open ground, where it rains *every day* nothing would be required but a border of a few inches around the elevated seed-bed, to keep the seed from washing away. In a place where the seed-bed might get very dry, however, a coarse fabric, say a covering made of bran-sacks, should be used. For the first few days, until the seed germinates, lay it flat on the ground, and it will keep the soil and seed from being disturbed while using the sprinkler, and guard against too heavy rains, and to give, partly, sun and shade. The bed is also warmed better by the sun, where thus covered. I have observed that a great amount of seed, money, time, and work, is annually lost because *seeds do not germinate*, even though the seed is good. The time is thereby irretrievably lost. While the seed is germinating, small strips of wood should be nailed on the frame, near enough to keep the cover a few inches above the bed. The cloth should be nailed to the frame, with laths at one side. It should be fastened with loops on the other sides, in order to open quickly and give the full sun if need be.

Closer attention is required by delicate and small flower seed. We sift on the seed about $\frac{1}{16}$ of an inch of sandy loam, and press it down with boards, in the fashion of using snow-shoes. The smallest seed does not require any covering, but only some pressure, and a shade for some days with a piece of cheese-cloth. Of course, the nature of the flower must be known—some require almost a full sun, and others nearly full shade. If the seed is sown in nearly dry soil it should not be immediately drenched. Better wait 12 or 24 hours. In watering we should imitate nature—water only when required, but then thoroughly. Imitate dew, with a syringe. Suppose seed is sown in damp soil, and pressed down, and the bed is allowed to become dry afterward; then a partial failure is sure to follow. The seed will swell immediately; and, if allowed to dry, will shrink again. The germinating power is then checked or destroyed. The result is, feeble plants, or none at all. Again, when seed is kept too wet at the start, it will burst open, and the same results follow. THEODORE LOHF.

Denver, Col., March 11.

RAISING POPCORN—A NEW INDUSTRY FOR THE BOYS.

Mr. H. R. Wright says: "We are hearing from our advertisement from every quarter." Inclosed with the above was the following, which we presume is in answer to inquiries brought out by his advertisement:

Dear Sir:—We bought last season 50 carloads of popping-corn of all varieties, and found the "eight-rowed" (or "Shaker") variety gave best satisfaction in every way, maturing earlier and yielding more per acre, and, having long ears and no nubbins, husks easier. Having a very small cob, it cures quicker and yields more shelled corn than any other variety. It has a large round kernel, and pops larger than any other. It is very white when popped, as all popping-corn should be, for no yellow, red, or any colored corn looks well when popped. If this variety of corn is properly cultivated it will yield per acre equal to common corn, and we never bought any less than 2½ to 3½ cts. per lb., which is about three times as much as common corn sells at. We buy all varieties, and will make a price at any time on receipt of sample. We want 100 carloads next season, at least. To make a sure success of growing it, procure the best possible seed. Plant early, and not near any other corn. Leave in the field on stalk as long as possible. Do not shock nor allow it to sweat in husk or anywhere else. Weather-cure as much as possible, and don't kiln-dry or force dry by any heat. The only proper way to cure corn is by freezing weather in a crib, or in an open building, spread out. It will always be ready to pop satisfactorily by January or February. You can't plant too much. We will buy all you raise, at good prices. We will select seed ears of any variety you wish, and send you, on receipt of 10 cts. per lb. for any amount you may want under 50 lbs., or 8 cts. for over that amount. H. R. WRIGHT.

Albany, N. Y., March 21.

[Now, boys, here is a chance for you; and I suppose the "new discovery" (pruning off the tassels) will work as well with popcorn as with any thing else. Why shouldn't it?]

RECIPE FOR CANNING PUMPKIN.

I have canned them successfully for two years, and used a mixture of field pumpkins. Cook till tender, put through a sieve, cook again as long as there is water in them. The secret lies in thorough cooking. I used tin cans, and sealed them with sealing-wax. MRS. J. K. MCCLURY.

Lima, Allen Co., Ohio.

MYSELF AND MY NEIGHBORS.

Feed my lambs.—JOHN 21:15.

Yesterday I had the toothache. I suppose it is a good thing to have the toothache once in a while. There are several lessons it teaches us. One is, to be thankful when we do *not* have it. Another is, to resist with all our might the temptation to be impatient and hasty when writhing under pain we can not escape. Another is, it bids us have sympathy for others when they are suffering. When it first came on I stopped it with Porter's Cure of Pain. Now, it has been so fashionable lately to go on about drugs and patent medicines, and the like, I do not know but I needed a little lesson of charity in that direction. The above remedy I do think a boon to mankind. It relieves pain almost instantly—that is, in the majority of cases. Finally, during the severe attack yesterday, however, even my old remedy did not suffice. I bathed my face until the tears ran from my eyes, and my mouth smarted so from the hot liniment that I could only walk the floor and pray for patience.

"But, why didn't you have the tooth pulled, Bro. Root?"

Well, I did not want to spare the tooth; and, besides, I remembered how fearfully it hurt me when I had just one tooth pulled, perhaps twenty-five years ago. I had been staying in a warm room, and keeping my face up by the steam-pipes, for many times I have found relief in that way. I happened to look out of the window, however, while suffering, and saw something in the new hot-bed that needed my attention. I put on my overcoat and rushed out, and got so busy directing the boys that I either forgot the toothache, or else the toothache forgot me; and then I discovered that I felt better out in the open air than I did in a warm room. How many things there are to learn in caring for these bodies of ours! and how often we blunder before we find out what nature wants! I did not have any more of the toothache until meeting-time. Revival meetings are going on at one of our churches; but as there was a cold damp east wind, my wife urged that I had better stay at home. Some way my conscience seemed to tell me, however, that I ought to be there. So I started. It is a full half-mile to the church. Before I got a quarter of the way, the east wind started my tooth to aching again, and I turned around, a little sadly, and went back home. I tried to have faith to believe that God had some *lesson* for me to learn, in a line with this toothache. But I could not see just how any good could come from being kept from church. I went back home with a rather small amount of faith, I must confess. I took a book and sat close up by the base-burner, and *this* time the heat of the stove seemed to drive the pain away. When I had sat there for perhaps half an hour, and finished the book I was reading, I looked at the clock and wondered whether I hadn't better go, even if it *were* late. With my thorough toasting by the stove I concluded I could keep pretty warm until I reached the church. I felt a little happier after I started. The sermon was more than half over, and I disliked to disturb the preaching. But there were no seats except away up in front. I started once to go up, but I hesitated and turned back. The usher whispered that I might get a seat among the boys at the other door. Now, I had not a glimpse of a thought that there was any *providence* in my being late, or in the fact that I must ask the boys to squeeze up together a little, and give me a seat in that particular corner. There was a great lot of boys all around me, some of my own, and one or two among them that I had not got along with very well. I remember wondering what had induced so many to come. From what I knew of them I did not think they ever had very many if any serious thoughts, and they did not look then very serious either. They were not noisy, but there was quite a little exchanging of glances, and smiling; and in my poor feeble attitude of heart at just that time I could not see that there was very much in the sermon to interest them. It seemed away above their heads. To tell the *truth*, I got drowsy, and I meditated slipping out and going home as soon as they commenced to sing the first hymn at the close of the sermon. One reason why I got drowsy was, that the only window that afforded any fresh air had just been closed. An old gentleman with a rather bald head found the breeze rather too much for him, and signified to the janitor to close it. As he shut it clear up, I almost gave a groan, thinking that my spirituality, for the evening at least, was about extinguished with that last bit of fresh air. Now, one of my crosses, as you may remember, is to be obliged to listen to a sermon when the room is full of bad air. It actually makes me stupid and sort o' crazy. I do not mean to find fault, because I am not now in a fault-finding mood. But I made up my mind, that, if *I* ever sat near a window, and found the draft was making me take cold, I would surely take a seat somewhere else, instead of asking to have the air all cut off from the rest of the congregation. The sermon closed, finally, and the pastor's wife gave an excellent talk to the boys; but the air was so hot and close that I had not much faith that even it could do anybody any good. Perhaps I had better say, that *Satan* suggested the above thought, and may be the air was *not* so very bad after all. If others did not notice it, then it was better for me to pray for grace to bear it as best I could. Finally they rose up to sing. The pastor's wife urged them to come forward and bring their friends. To my surprise, quite a young boy—in fact, the youngest printer in the office where I am writing—commenced going to one and then to another of his companions, exhorting them to come right along *that night*, and make a start in the Christian life. I was surprised at the ease and self-possession with which he (usually bashful and diffident) undertook a task that would have been a hard one for myself. But when another young boy in my employ *assented*, and started to go with him up to the altar, I was still more surprised. A lot of young girls started in the same way. I began to wake up. I looked about me and caught the eye of one of the boys I have been praying for, and who works near me almost every day. Then I remembered something that his aunt had said to me some time before. It was something like this:

"Mr. Root, you do not know what a high opinion E. has of you. He thinks whatever *you* say is law and gospel, and I do believe that a word from you would have more effect than any thing the minister or even his *own relatives* could say to him."

Could it be that this boy was thinking of going forward too? and was it possible that an invitation from *myself* was all that was needed? But then I remembered that, only a few days before, somebody had heard him swearing right straight along, and that, too, when he was at play, and not angry with anybody. Something said, "Why, Mr. Root, it is not of any use; it will not be *best*, anyhow, to ask a boy to come forward to the anxious-seat who does such things as that. There can't be any *real* desire about him to be a Christian." Just at this point, however, they started up

"Just as I am, without one plea."

I prayed that God would guide me. Then I moved over to where my young friend sat. I talked with him some, but he was bashful and backward; yet something in his look seemed to tell me that the Holy Spirit was at work in the child's heart. And then I remembered how earnestly *I* had prayed for the Holy Spirit that morning, when I first got out of bed.

"E., will you not come forward and make a start for Christ, if I will go along with you to the anxious-seat?"

He looked me square in the face as he replied promptly and decidedly, "Yes, Mr. Root, I will go."

I went up with him, and whispered to the pastor's wife that I had brought one of my boys. You can not think how her face lighted up as she took him by the hand. She and her husband had been laboring for two weeks, working hard and earnestly, to the end that the result of the union meetings which we have been holding all winter might not be without a general revival. I knelt beside my young friend, and prayed for him. But another boy's face kept getting before me. It was the face of one with whom I had had much difficulty. That is, he had been reported so many times for bad behavior that I had talked with him again and again, and had even suspended him; and he had been dismissed finally, as I had supposed, only a few days before. After every reprimand, however, he had confessed his fault, and begged to be tried again. This had failed so many times, however, that I had lost heart. Just the day before, he said, with tears in his eyes, "Mr. Root, I know that I do not deserve another chance. I know it is just as you say, and I do not see what *is* the matter with me. It does not seem to be of any use for me to try to be good."

His principal trouble seemed to be, he was so full of fun and mischief that he not only wasted his time, but he hindered others more than he earned, and I got to thinking that forbearance had ceased to be a virtue—that he really did not *care* very much after all. This boy, however, had come to meeting; but I looked at his face and decided that he had come more out of a spirit of fun than for any thing else, and I gave up thinking it would be best to ask him to come forward. Then I thought of my little text—"O thou of little faith!"

I left the anxious-seat and went back, and pushed past the other boys until I came near A.

"A., do you not believe that, if you and I both should go forward to that anxious-seat, and both take a start on the rock Christ Jesus, we could get along together in our business relations? Will you not come forward if I go with you as I did with E.?"

"Mr. Root," said he, "I am ready to try it." And then I knew he was in dead earnest. I led him up, amid a general rejoicing. Now, dear friends, several temptations beset me at this point. I have been getting older and steadier within the past few years. I hope I have been getting where God can consistently trust me with spiritual prosperity. But after *two* boys had come right along with only a little exhortation, it seemed to me that I was going to get all of the boys in that corner—yes, whole seats full of them. Well, I am not sure but that such a thing *might* have been possible, if nothing but *Christ Jesus* had shone from my face when I went back to talk with them. The third one had started, and I thought he was coming forward. Then he hesitated, and said that he was afraid that he was rather young to take such a step. I talked with several more; but the example of one holding back had at least some effect on staying the rest. I was like poor Peter when he started to walk on the water, and began to get a little vain of my success. Now, somebody may ask right here, "Mr. Root, why do you take it for granted that it was a wise thing or the best thing to ask those boys to come forward, under the circumstances, especially the very young ones? Is it well to have them make such a start without counting the cost, and then have them give up and go back, as so many of them do?"

Well, I have studied on this matter, and I have prayed over it a good deal, and I have for years watched the result on boys who have thus started. "It *is* well to have them start. I never knew a boy to make such a start but that it proved to be a safeguard and a protection round about him. If he has been swearing, the consciousness of having made such a public promise is quite sure to keep him from it. Unless something extraordinary happens, the result of making such a start (in any of our churches) has always been, so far as I know, *good* and only *good;* and it almost always proves the turning-point in the boy's life. It often results in a complete change of companions and associates. The books he reads begin to assume a different character. His purposes and desires at once begin to change. He begins to *love righteousness* and to *hate iniquity.*"

As we knelt at the anxious-seat, a whole long row of us, a heavy responsibility began settling down upon my poor self, and I began to pray most earnestly, "O Lord, help me to remember the exceeding sacredness and solemnity of the step *I* have taken to-night. These young friends have given me their confidence; they have decided to be guided by my wisdom, and the future with them largely depends upon my poor self. Is it possible that I shall forget this sacred time and place, and be harsh and severe, as I have been in times past, perhaps, when these poor boys were doing the very best they knew how? Lord, help me to have more charity and more willingness to overlook mistakes; and help me to keep in mind more constantly the fact that *I* was a boy only a few brief years ago. Lord, help me in this most important duty that now devolves upon me, of "feeding" and ministering unto the precious "lambs" of thy fold. Help me to be more patient; help me to be more kind; and if it be indeed true that these (the lambs of thy fold) are looking to me with more faith and confidence than toward their pastor or relatives, O Lord. *help* me to be worthy of this confidence they have seen fit to repose in me. Help me to believe that, if they do not hold out, it will be largely my own fault."

I felt at once, as soon as I began talking the matter over with these boys, that *they* greatly feared they might not hold out, or that they might do something that would be inconsistent with even a young follower of Christ; therefore we were, as it would seem, standing on common ground. I am older than they, and I have been years in Christ's service; I am a teacher and an exhorter. They look to me with confidence, and wish my opinion in regard to this matter of starting out to be a Christian; therefore it is far more important that *my* example should be good and wise and kind. I feel to-day, it seems to me, as I never felt before, how much we need grace from on high. Yes, I need it just exactly as the boys need it, for more is required of me. And it is not the boys alone that live here in *Medina*, or that work at our factory who need praying for. It is the boys all over the United States of America; nay, wider still—the boys all over the wide world—the lambs of the flock. And the *boys* are by no means the only *sinners* concerned. The ministers have a responsibility to bear, and the parents and teachers. Jesus said to Peter, "Feed my lambs." Now, there are not only lots of lambs to be fed, but there are lots of Peters who are doing the feeding. May God help the Peters! May God help you and me, my friends!

I have been told that the children read these Home Papers, and the young men; and I know many parents and spiritual teachers read them also. In view of what I have said this morning, do you not, dear friends, all of you, feel the responsibility and the need of a deeper work of grace in your hearts? In view of this shall we not pray ever so much more earnestly than we *ever* have before, "Give us, O Lord, of thy Holy Spirit that we may discharge well and faithfully this office that we can not escape, and that so continually devolves upon us, of feeding and caring for the lambs of thy fold"?

The next evening I succeeded, through Christ Jesus, in bringing forward another of these boys. But this was the close of the revival meetings, and some way the boys had got a start in this new life, and it did not seem best to stop the meetings entirely; therefore two more meetings were held the present week. They were not so well attended as formerly, but there were many young people present. The pastor invited me to talk 15 minutes the last evening. Some way, when I planned my talk those boys and the young people kept coming up before me in my mind's eye again and again. I chose for my text, "The wages of sin is death; but the gift of God is eternal life through Jesus Christ our Lord." Before I began speaking, the pastor said something like this: "Mr. Root, the people of Medina could not have paid you any higher compliment than they have. See the youthful faces before you, and especially a lot of boys who have come to hear you talk. If we get the children we shall have the parents by and by." At the close of my talk, two more boys rose up and declared before the congregation that it was their purpose to serve Christ Jesus henceforth and for ever.

At the close of the meeting the good pastor called them all up around him; and by encouraging words, each boy rose to his feet, one after another, and gave his testimony in a few simple words. Many of these boys were so exceedingly bashful and timid that it was a very great cross indeed for them to speak in public at all. But their bright and smiling faces, after they had borne their cross in their own boyish way, would certainly have convinced anybody of the honesty and sincerity of the work in their own hearts. One young friend, who assists in the counter store, spoke something like this: "It pays to be a Christian, because it makes one feel happy while about his work, all through the day." Most of the testimonies were about as brief, and much in this line; and when I meet these boys as I pass along through our different departments, the very sight of them does me good. The report comes from the bosses of the different rooms, that they could not ask for better boys than we have now. And yet this is the report we get of some who had made us the most trouble before our revival meetings. Now, friends, does it very often, if ever, happen that any one starts out to follow Christ before he is old enough? Remember the injunction, "Feed my lambs."

GLEANINGS IN BEE CULTURE

A Journal devoted to Bees and Honey and Home Interests

And when thou art converted, strengthen thy brethren.—LUKE 22 : 32.

BEES in "our cellar" are doing well—none lost so far, that we can see. April 15th may tell a different tale, however.

DR. MILLER tells how, without perforated zinc, to raise queens in a colony already having a laying queen, on page 270. It's a good suggestion.

WE learn from one of our French exchanges that there are in Germany over 20,000 members in the various apicultural societies of that country, and that the annual product of the bees exceeds 22 million francs.

IT takes extraordinarily good editing to boom a bee-journal that uses poor paper and ink, and is otherwise slovenly in typographical appearance. Perhaps some of the bee-journals that have started this year may take a hint. Bee-keepers are good judges of printing as well as some other folks.

EDITORIALS AND STRAY STAWS.

DR. MILLER says, on the first page of the journal, that the editorials are "covering so much ground in an interesting manner that, in a little while, I shall have nothing to manufacture Straws from." Why, doctor, you are crowding on one end of the journal, and we on the other. We shall have to quit crowding you, that's all.

ANOTHER NEW BEE-JOURNAL.

VOL. I. No. 1 of the *Missouri Bee-keeper*, a monthly edited by E. F. Quigley, is before us. It contains 16 pages, with a neat tinted cover, and its first appearance is good, compared with the way a good many bee-journals start. Let's see: A month ago or so we said we counted up seven bee-journals that had started since Jan. 1, and this one makes the eighth.

A SUGGESTION TO CORRESPONDENTS.

WE should be obliged to the writers for GLEANINGS if they would scatter head-lines through their articles. We are much more apt to choose such, when they are plainly written, than we are articles with no head-lines and no indication what they are about. Very often, by glancing through a manuscript, the head-lines give a hint that the article should be used at once, if at all. While there is such a great stack of unused manuscripts, and good ones too, those published will usually be the ones that are prepared and ready for the printer, other things being equal.

CLOSED-END FRAMES FOR MISSOURI.

THE editor of the *Missouri Bee-keeper* says that closed-end frames are his choice. He says: "We can handle them better than any hanging frame, and they are always properly spaced." Elsewhere in the same issue he says: "We put a few closed-end frames in our apiary three years ago, and have been increasing the number ever since. . . . . Our best yield has always been from colonies on closed-end frames. They build up early in the spring. A hive with closed-end frames and winter case is the coming hive." Last issue we asked whether closed-end frames were practical in the South, and intimated that possibly propolis might be so bad as to make them intolerable. As far south as Missouri they are not as intolerable as they might be. How is it further south, friends?

THE USES OF BASSWOOD IN LINN CO., IOWA.

WE are informed that there is a county in Iowa, named after the great number of basswood (or linn) trees, and it bears, therefore, the name of Linn Co., Mr. J. S. Stoneking, residing in that county at Bartram, says there is a plenty of basswood timber in the county, and, in fact, in all eastern Iowa. The railroad companies bought at Bartram, his postoffice, 3500 cords of wood, at $2.00 a cord, in 1891, a fourth of which was basswood. It makes the heart of a bee-keeper fairly ache to think of desecrating basswood for cordwood. It is bad enough to use it for sections, furniture, packing-boxes, and paper. Our correspondent says they also use the wood very largely in his vicinity for making kegs and barrels. This is certainly a better use to make of such valuable timber.

LARGE OR SMALL BEE-KEEPERS; THE DIFFERENCE BETWEEN THEM.

WE do not despise the small bee-keepers—oh, no! They often give us some of the best ideas and short cuts; but when a large bee-keeper, who owns over 500, 600, or, if you please, over 1000 colonies, is enthusiastic over a certain device, and he knows from long practical experience of its successful working, we feel as if his statement could not be lightly esteemed. Editors have been accused of overlooking the little bee-keepers, and seeking articles from the big bee-guns. There is some truth in it, but they naturally go where they can get the best information—that which rings with *experience*, and is redolent of the aroma of honey and the wax, and of the much-despised propolis. If a man with his thousand colonies finds a thing to be a success that is a money-maker, it will *probably* work pretty well, even with as small a number as ten colonies; but, mind you, you can not reverse this. What gives good satisfaction with ten or even a hundred colonies may not necessarily do for several hundred stocks.

FORECASTING RESULTS IN EXPERIMENTING; A SUGGESTION FOR EXPERIMENTAL STATIONS.

AN experimenter should be unbiased. When he starts out on a series of experiments to prove or disprove, he should be just as willing to arrive at one conclusion as another. The trouble with so much experimenting is, too much forecasting of conclusions; and the experimenter himself is quite inclined to make the thing come out just as he wants it to, on the principle of "I thought so," or, "I told you so." In other words, he should be just as willing to have his pet theories utterly annihilated as to have them substantiated. The man who says, "I told you so," or, "I thought so," when a thing happens to come out so and so, shows that he *wanted* the result to be so and so, no matter whether it be good or evil. It is just this disposition in human nature that makes the world a great deal of trouble; and, barring the one factor of locality, it explains more differences of opinion and more differences in conclusion than any other thing in apiculture. E. R. R.

ALUMINIUM—THE NEW METAL.

WE have just received 100 beautiful three-inch machinist's rules, made of *pure aluminium*, divided into 8ths, 16ths, and 32ds of an inch. This metal is almost as hard as silver, and so light that the rule will float on water if laid very carefully on the surface. This seems almost incredible. In fact, when one takes it in his hand he is almost startled to find that, although it looks like steel, it is almost as light as wood. It is as proof against rust and tarnish as gold itself, and even at its present price (about $1.00 per lb.) you *get so much* it already promises to be a formidable rival to brass; and when we recognize that it is better than silver to hold its luster, it seems to be destined at once to take the place—at least to a great extent—of both silver and copper. We can send you one postpaid by mail for only 25 cts. Steel rules, made as accurately as these are, usually cost 50 cts. or more.

MOVING A CARLOAD OF BEES TO COLORADO IN THE DEAD OF WINTER—A SUCCESS.

THE project of sending a carload of bees from Eastern New York to Fort Collins, Colorado (see p. 70), in the dead of winter, proved to be a success. We have just received a card to-day, March 26, which reads as follows:

> My carload of bees came through to this place Saturday evening, and were all unloaded the same night, and they had a good fly yesterday. I had unexpected success in getting them here in good condition. I will report particulars later.
>
> Fort Collins, Col., March 23. O. R. COE.

This success is phenomenal, and our friend Coe is to be congratulated. We were afraid he might have trouble in the dead of winter. He is not only now in a place where he is free from losses in winter and spring dwindling, but he has his bees where they commence gathering alfalfa honey soon—quite a scheme.

HOLDING A GRUDGE.

OUR friend W. I. Chamberlain gives us a bright thought in the *Ohio Farmer*, as follows:

> Then here is another man whose name is a "common noun, Smith." He thinks I don't like him because he once criticised an article of mine in the *New York Tribune* (which I had forgotten if I ever knew it), and once asked some hard questions at an institute (which also I had forgotten). Bless his dear heart! if I had laid up a grudge against every man of that sort, my soul would need a thousand pigeon-holes, all marked "grudge," and variously classified.

How many times this comes up through our correspondence! Somebody will have it that I am prejudiced, or that I have a grudge over something that has happened in the way of business. It reminds me of what Prof. Cook once said when I told him I feared I had hurt his feelings by something I had said carelessly. He replied: "Why, bless your heart, Bro. Root, this world is too full of important matters for us to take time to feel hurt, especially when we know each other as you and I do."

AN INGENIOUS COMPLIMENT.

SOMETIMES we get orders to stop GLEANINGS; but here is a subscriber who says he does not want it any *longer*. See:

> I do not want you to send GLEANINGS any *longer*; but how I wish it were a little *wider* and a good deal *thicker!* CHESTER OLMSTEAD.
>
> East Bloomfield, N. Y., March 28.

GOOD NEWS AT THE HOME OF THE HONEY-BEES.

JUST at the last moment, as we go to press, all things are brought to a standstill to announce the advent of a grandson to the founder of the Home of the Honey-bees. Ernest is going around full of smiles, and is as proud as—well, as proud as a young man ought to be when he first feels the thrill of being father to a eight-pound boy. He arrived Easter Sunday, March 29. A. I. R.

SOMETHING NEW IN THE LINE OF SMOKERS.

OUR friend Hill, of the *Bee-keepers' Guide* (it just now occurs to us that he has *not* been quite as friendly as he might have been, but never mind), has just gotten out something in the line of smokers, that, so far as we can judge by engravings, is, in many respects, ahead of any thing heretofore offered. The idea is so novel and unique that one feels ashamed of himself because he did not invent it long ago. My impression is, at the present writing, that he is entirely original in the idea. It is a cold-blast smoker, but it has a straight barrel, like the Bingham. The blast-tube is straight, so it is the easiest thing in the world to clean it, and yet it opens and shuts to put in fuel, handier and easier than any thing heretofore brought out; and the whole thing, when held in the hand, comes in just the most convenient shape for use. Send us an electrotype, friend Hill, and we will give your invention the notice it deserves, free of charge.

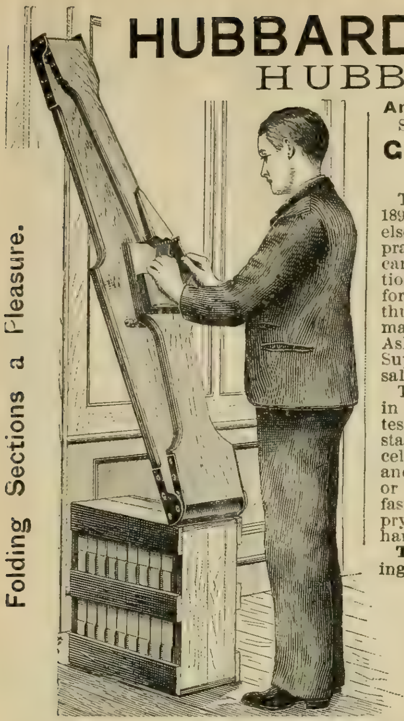
DADANT'S LATEST MASTERPIECE.

As if not satisfied with the laurels which he has just won in the English-speaking apicultural world in his revision of Langstroth's book, Mr. Dadant has just given to his own fellow-countrymen of France the same work, adapted, as nearly as can be, to that land. Side by side, the two books look exactly alike at first glance. The English book is a little thicker than the French, although the latter contains 73 pages more than the English work. One of the happiest things about this great undertaking is the just prominence which Mr. Dadant gives to those who helped him—particularly Mr. Charles F. Muth, of Cincinnati. In this connection we beg leave to translate a few lines. After speaking of Mr. Langstroth's inability to revise his own book, on account of his brain troubles, Mr. Dadant says:

> Having had knowledge of his desire, and of his futile attempts to accomplish so heavy a task, we thought (my son and I) that we would offer him our assistance. By the aid of our friend Charles F. Muth, who was enthusiastic over our project, the plan was soon carried out. After our conferences Mr. Langstroth was to pass in review all of our work, pointing out our oversights, suggesting ideas, etc. In consequence, the revision should have been called "Langstroth and Dadant." Unfortunately our friend's sickness rendered him incapable of doing the work. We continued writing, nevertheless, and, quite naturally, inserted his beautiful periods without marking them, thinking always that his name would appear in the title-page of the work. Finally it became necessary to do entirely without his assistance, but the idea did not occur to us to insert, in the English edition, published by us in 1889, some mark to indicate what we borrowed. Mr. Bertrand, of Nyon, Switzerland, having pointed out this omission, we have made every effort to discover what we copied, and have inserted it in brackets in the French edition, happy to render to our friend the honor that belongs to him.

HUBBARD SECTION PRESS,

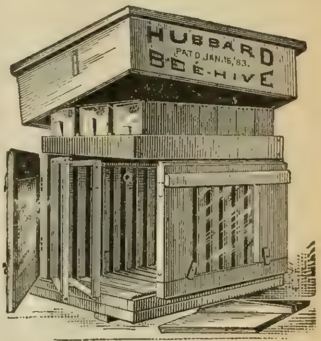
HUBBARD BEE HIVE,



Folding Sections a Pleasure.

And other Apiarian Supplies.
Send for descriptive circular,

G. K. HUBBARD,
Fort Wayne, Ind.



This Section Press (Pat. June 17, 1890) is far in advance of anything else of the kind on the market. It is practically automatic. Both hands can be used to handle the sections, and a slight forward push forces together the dovetailing, thus completing the sections with marvelous rapidity. Price $2.50. Ask your supply dealer for it. Supply dealers, send for wholesale prices.

The HUBBARD HIVE has been in use 8 years, and has stood the test nobly. Trade has been constantly growing, owing to the excellent satisfaction it gives. If you are ever annoyed by the scraping and breaking of combs; killing bees when setting a frame to one side or hanging it in the hive; sagging at the bottom and getting waxed fast; shaking about when moving a hive; in short, if you dislike to pry and wrench your frames, break combs and kill bees while handling them you will be pleased with this hive.

The Man Who is Willing to Work can make money fast selling these hives. **$5.00 to $10.00 often made at it in a day.** Send for Circular.

SECTIONS, SMOKERS, DADANT'S COMB FOUNDATION, ETC.

15c. For revised "1st Principles in Bee Culture." 104 pages—the *largest and best work of the kind for the price.* First 68 pages contain no advertisements, but are filled with such practical information as how to divide, transfer, introduce Queens, feed, unite, stop robbing, raise honey, etc. The book receives many compliments. If you do not like it, return it and get your money.

Advanced Bee Culture; Its Methods and Management.

I am now engaged in writing and printing a book that is to bear this title. It is to take the place of my other book, *The Production of Comb Honey*, which will not be re-published. Although the new book will contain at least five or six times as much matter as *The Production of Comb Honey*, yet the price will be only 50 cts. The book is already partly printed, and will probably be out some time in April or May. If any of the friends would like to "help me along" in meeting the expenses of getting out the book, they can do so by sending their orders in advance. Such orders will be most thankfully received, and filled the *very day* the book is out. I will send the Review one year and the book for $1.25. The Review will be sent on receipt of order (I have plenty of back numbers to send it from the beginning of the year), and the book as soon as it is out. Stamps taken, either U. S. or Canadian. 10tfdb

W. Z. HUTCHINSON, Flint, Mich.

KIND WORDS FROM OUR CUSTOMERS.

I bought one of your Popular Histories of the Civil War last fall for 75 cts., and I would not take $5 for it if I could not get another. It is a fine book for so small a price. W. A. Peck.
Brunswick, O., Jan. 9.

KIND WORDS FOR OUR 1891 SECTIONS.

The goods you shipped to me by freight came through all right. The freight on the whole amount of 815 lbs. was only $10.40. The sections are just simply beautiful. Nothing was damaged in the least. Willie Douglas.
Lexington, Tex., Jan. 18.

The shears came to hand. They were for a Christmas present for my better half, and she was so highly pleased with them that she has shown them to her lady friends, and they are so pleased with them that they all want a pair, so I order ten pairs. Wm. Dyer.
Hastings Minn., Jan. 4.

OUR $12 SEWING-MACHINE.

Our sewing-machine came to hand in good order, and does as good work as a fifty-dollar machine. It certainly is a marvel for the money. Freight was $1.60. J. H. Archer.
Mt. Calm, Tex., Jan. 1.

GLEANINGS FOR ADVERTISING.

Please discontinue my advertisement, as I have received a considerable number of replies, and can surely make a selection from them. I find Gleanings is a splendid place to put an adv't to reach the eye of the public. Please accept thanks.
Monongah, W. Va., Feb. 28. S. Ray. Holbert.

WASH AND BE CLEAN.

What you say under the head of "Wash and be clean" is just what I have been looking for in every number of Gleanings; for I felt sure that it would come, sooner or later; and I thank you for it —not on my own account (for I had found out the remedy without the $4.00), but for humanity's sake.
Leon, Wis., Mar. 7. B. F. Fox.

HOW OUR COMPOUND ENGINE WORKS.

The engine works all right, except the bolts that connect the boxing on the main-shaft journal. They will work loose while the engine is running, and I have to stop very often to tighten them up. Perhaps you can suggest a remedy. I wish to tell you the good points about the engine that I have learned so far. My boiler is only 16 inches in diameter by 40 inches high. I have no trouble in keeping the steam at 120 lbs., and we run our hive machinery and a heavy 12-inch emery plow-share grinder at the same time, without any trouble, only as noted above. A. B. Herman.
Burnett's Creek, Ind., Mar. 10.

My goods were received in San Francisco Dec. 31. Every thing was correct. I am especially pleased with the section-former. It does beautiful work. Rate from Reno, $1.18; only about $3.00 saved.
Bouldin Island, Jan. 26. H. S. Thomas.

THE NEW IMPROVED DOVETAILED HIVE.

You have made some grand improvements on the Dovetailed hive, for I find the honey-board stuck fast every time with the old hive. However, I think the improved hive will do better. Don't go back on that outside shell for wintering. That strikes me as just about right, if it is put up well so it can be painted, as the senior said. A. T. McKibben.
Flag Spring, Ky.

A GOOD TESTIMONIAL FOR OUR ANEROID BAROMETER.

The aneroid barometer came to hand in good order, Tuesday last. I am more than pleased with it, and consider it the best investment for the money I have made for some time. I have used both mercurial and aneroid instruments costing several times the amount; but I ask for no better than the one you sent me. J. Y. Detwiler.
Toledo, O., Feb. 28.

CHARLES H. IRWIN. PAT. OCT. 21–1884.
IMPROVED APR. 19. 1887.

This is a superior bit formed from a steel rod. The spiral is rolled out by very heavy pressure of a special machine. They are guaranteed to always run free.

PRICE LIST.

Sixteenths	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20
Price each	25	25	28	31	35	38	41	45	48	51	55	60	65	70	75	80	85
Postage each	2	2	2	3	3	3	4	4	4	4	5	5	5	5	5	5	5

The first row of figures gives the size in sixteenths, the second the price each, and the third the postage each, if sent by mail. In lots of 5 or more, 5 per cent off, or a full set, 10 per cent off.

A. I. ROOT, Medina, O.

New Orleans Apiaries.

Italian and Carniolan bees and queens for sale.

Send in your orders now, and the money when bees or queens are wanted. Purity and safe arrival guaranteed. Address 7d

J. W. WINDER, 572 MAGAZINE ST., NEW ORLEANS.

Mention this paper.

FOR SALE. 50 colonies of bees in new hives, Simplicity frames, at $5.00 per colony. One-half cash, balance on time to suit the purchaser, with good security. 8-9d THOS. GEDYE,
Kangley, LaSalle Co., Ill.

FOR SALE!

50 TO 75 COLONIES ITALIAN BEES.

Big discount on nailed hives for next 30 days. Send for catalogue.

O. H. HYATT, SHENANDOAH, IOWA.

Black and Hybrid Queens For Sale.

Six fine mismated Italian queens, 40 cts. each.
F. C. MORROW, Wallaceburg, Ark.

I have 17 mismated queens in an out-apiary that I will sell April 20th, at 35c each, 6 for $2.00.
W. H. LAWS, Lavaca, Ark.

During April I will sell 40 hybrid queens, all of last year's raising, at 40c each, or 3 for for $1.00.
G. OBERKAMPF, New Braunfels, Comal Co., Tex.

Mismated queens at 50c each. Satisfaction guaranteed. D. D. Hammond, or Eden Valley Apiary, Malone, Ia.

Twelve hybrid queens for sale, 60 cts.; raised last fall. E. GREELEY, Lorain, Lorain Co., O.

We have in the South some 15 hybrid queens and some 12 black ones which we shall be glad to dispose of. We will furnish the hybrids for 75 cts. each, and the black ones 35 cts. each.
A. I. ROOT, Medina, Ohio.

Wire Cloth.

For door and window screens, tacking over hives and nuclei for shipping, making bee and queen cages, and a variety of purposes. We have the following list of green and black wire cloth which is not exactly first class, but is practically as good for the purposes mentioned, and at prices MUCH BELOW the ordinary price. You can no doubt select from this list a piece to suit your needs. Price in full pieces, 1¾ cts. per square foot. When we have to cut it, 2 cts. In case the piece you order may have been taken by some one else before your order comes, please say whether we shall send the nearest in size, or cut one the size ordered at 2 cts. per ft., or give a second or third choice.

No. of Rolls, and Color.	Width, In's.	Length, Ft.	Sq. Feet.	Price of a Full Roll.	Pieces less than 100 ft. long. These figures are the number of square feet in each piece. Multiply by 1¾ cents for the price of piece.

Cash for Beeswax!

Will pay 28c per lb. cash, or 30c in trade for any quantity of good, fair, average beeswax, delivered at our R. R. station. The same will be sold to those who wish to purchase, at 33c per lb., or 37c for *best selected wax*.

Unless you put your name *on the box*, and notify us by mail of amount sent, I can not hold myself responsible for mistakes. It will not pay as a general thing to send wax by *express*.
A. I. ROOT, Medina, Ohio.

Job Lot of Wire Netting.

CUT PIECES AT A LOWER PRICE THAN FULL ROLLS.

Having bought from the factory, at our own price, five or six hundred remnants, as listed below, we are able to give you the choice of a great variety of pieces at the price of a full roll or lower. Full rolls of netting are 150 ft. long, and when they are cut we have to charge nearly double the full-roll rate, because it is so much trouble to unroll, measure, and cut, and run the risk of having a lot of remnants on hand. No doubt it is in this way that the following remnants have accumulated. It costs a good deal to get all this in shape so we can easily pick out from the lot the piece you want. But to move it off quickly, we put the price down so you can all have a chance at it. Remember, first come, first served. In ordering, therefore, name a second or third choice, or say that we may send the nearest we can if the piece selected is gone. On 5 pieces deduct 5 per cent, on 10 pieces 10 per cent. These remnants are shipped only from here. If any of you want to secure some, and don't want them shipped till later, when you will order something else, so as to save freight, pick out the pieces you want, send remittance with the order, with request to lay by till called for, and we will mark them as belonging to you. We prefer to ship them right out, however.

LIST OF POULTRY-NETTING REMNANTS.

Width in in's.	Size of Mesh.	No. of Wire.	Cts. p'r Sq. Ft.	Length of each piece. Multiply by the width in feet to get the number of square feet in each piece. Then multiply by the price per foot for the price per piece.

GLEANINGS IN BEE CULTURE

A JOURNAL DEVOTED TO BEES AND HONEY AND HOME INTERESTS.

Published by A. I. Root, Medina, O.

Vol. XIX. APRIL 15, 1891. No. 8.

STRAY STRAWS

FROM DR. C. C. MILLER.

DON'T TINKER with your bees unnecessarily.

SUGAR has a two-cent bounty. How about honey?

A GENERAL CALL for State associations. World's Fair.

B. E. RICE (*A. B. J.*) thinks painting hives "a loss of both time and money."

QUEEN-EXCLUDERS, says the *B. B. J.*, are indispensable in working for extracted honey.

A STANDARD FRAME may yet be adopted in California, according to a report in *C. B. K.*

I WISH friend Corneil had included a double wall without packing, in the experiments reported on page 207.

ST. PATRICK'S DAY, March 17, my four colonies outdoors had a good fly—I think the first full flight in four months.

EGGS ARE DESTROYED for me in queenless colonies in the hottest weather, as well as cooler. This in reply to G. E. Fradenburg, p. 229.

ANOTHER. The *Missouri Bee-keeper*, Unionville, Mo. Nicely printed, in type big enough for those hard of hearing. E. F. Quigley, editor.

ADULTERATION! Styan says that *straws* get into the cream he furnishes in *C. B. K.* Still, that may be borne if he doesn't water his cream too much.

"A LITTLE MIXED" is that last item on p. 229. Mr. James uses hives of bees to hatch chickens, but the Medina folks use hives without bees. Isn't an old hen better?

A BIG COUNTRY this. I didn't realize how big when I wrote my little hymn, "In January . . . . the bees store nary a drop." The *California Bee-keeper* says that won't do down there.

WOODEN SHOES are worn and liked by Mrs. Harrison. They keep the feet warm and dry. I had a pair. I don't know what became of them. I think my wife didn't like the looks of them.

AN ITEM on page 230 is headed, "A colony of bees which secrete no propolis," as if that were something strange. None of my bees secrete propolis. They just gather it from trees or something.

PORCELAIN DOOR-KNOBS get loose. One of ours got loose the other day, and, instead of throwing it away as usual, I put it into the fire with the metal shank in it, took it out when the lead melted, and it was as solid as when new. But it cracked the porcelain somewhat.

COWAN'S NEW BOOK. I've read it all through, although some of it was pretty hard to understand. It was like taking a dose of medicine a little, but I feel the better for it afterward. It's a capital book.

THAT OLD FRENCHMAN, Ch. Dadant, is not in his dotage, by any means. A strong and well-written article from his pen, of four pages, in the *Revue Internationale*, defends Father Langstroth against the charge of copying Debeauvoys and others.

A NEW THEORY of foul brood. A. Leech, in *A. B. J.*, says the moth-miller lays eggs in the cells beside the queen's eggs, which hatch out, suck the food from the bee larvæ, which die, causing foul brood. As the newspapers say, this lacks confirmation.

THE CHICKENS scratch up the posy-beds every now and then, and then your wife sheds a few quiet tears. I'll tell you how to make her happy. Fence in the beds with poultry-netting two feet high. You can step over it, but the hens don't know enough to fly over—at least our Plymouths and Banties don't.

AFTER PUTTING my bees in the cellar I noticed that they didn't hang in as large clusters under the frames as in the preceding winter. I didn't know why. To-day, March 18, the cellar being colder than early in the winter, the clusters are much larger than then. I don't know why. Do you?

HERE'S A "WRINKLE" from Walter Marshall, in *B. B. J.* He thinks the reason that some have trouble in using, for the second time, sections partially filled, is because of propolis on the edges of the cells. So he scrapes off the surface of the comb to within ⅜ of an inch of the midrib, early in the season, when the wax is brittle with cold. There's no slow working, and no *old* look when done.

MELILOT. Bignens, in *Revue Internationale*, reports a profitable crop of melilot, getting a good crop of honey during its bloom, while surrounding bee-keepers a mile or two distant got little or nothing. It was sown with barley, and sheep and cattle ate the straw greedily. Mr. Bertrand, the editor, says his pony ate a mixture of oats and melilot, and the pony much preferred it thus "perfumed" to the clear oats.

"WE" or "I"? Bro. Newman says "we" has the indorsement of Ernest on account of the plurality of editors. Yes, it's all right to say "we" for two. We do at our house. But when it's I, say I. I see the "I" is used in GLEANINGS in 15 different editorials where "I" was meant. Bro. Newman thinks "we" looks better. That's a matter of taste. He says "we" "has the indorsement of many centuries." True, and so it has for the chief ruler of a nation, and yet to-day the chief ruler of the greatest nation on earth says "I."

WAX SCALES are found, plenty of them, wasted on the bottom-board, when a swarm is hived in an empty hive without foundation or comb. Few or no wax scales are found on the bottom-board of a colony run for extracted honey, if they have abundance of empty combs. The case should be exactly reversed, if bees secrete wax whether needed or not. See the bearing on page 212, friend Root? I'm with Prof. Cook, but I can't answer your argument.

FOUL BROOD. S. Corneil, in *C. B. J.*, says foul brood may be carried in foundation. Melting in a sun extractor will not kill it, and heating to 160° in making foundation will not kill it. To be entirely safe, it must be heated to 257°, or kept at 200° for some days. D. A. Jones thinks this a case where "science and practice do not agree." He thinks "the heat necessary in making foundation is great enough to destroy the germs of foul brood." The thing needs careful consideration. See editorial, page 341.

GENERAL CORRESPONDENCE.

MANUM'S NEW METHODS OF RUNNING SEVERAL APIARIES ALONE.

SIX OUT-APIARIES AND ONE AT HOME, AND NO HELP TO BE HIRED.

"Why, how do you do, Henry? Walk in, and have a seat. How do the chickens prosper, and how many have you?"

"Well, Manum, I am pretty well; and as to the chicks, they are doing well. I have now 500, from two to six weeks old, and 500 eggs in the incubator."

"Well, well, Henry; you are going into the broiler business rather heavy, I should judge. You must think it a profitable business, or you would be more moderate in your new venture."

"Yes, I think it will pay better than the bees have for a few years past, though I shall not give up the bees, but work the two together; for, you see, the main work and attention with the chicks comes at a time when I can do nothing with the bees, as I start my incubators in December, and aim to dispose of my chickens by June 15th, after which my whole time is devoted to the bees."

"I believe, Henry, you raised a few broilers last year. Did you keep an account of the cost of raising them, so you *know* for a certainty that there is a profit in raising them?"

"Yes. I kept both debit and credit, and I know just what profit was made. Myself and partner cleared just $106.00 on 175 chicks, and expect to make a better average per cent this year with our new brooder-house, and better facilities. But, Manum, I came over to talk bees with you, and to ask you how you propose running your bees without help this season, if your method is no secret."

"No, Henry, I have no secrets pertaining to the bee-business, therefore I will try to explain to you, as best I can, just how I propose to manage.

"First, I shall do all in my power, through the month of May—by contracting and feeding—to stimulate brood-rearing, in order to get a large force of workers hatched out by the time clover blossoms, which is usually about June 10th; and as then is the time swarming commences, I shall remove the queens from such colonies as have started queen-cells, or that show any signs of preparing to swarm; then in eight days I remove all queen-cells found in these hives, except, perhaps, from one or two that I wish to rear queens from. In these I allow the cells to remain until they are old enough to transfer to the queen-nursery to hatch; and perhaps at this second visit I remove fifteen or twenty more queens, and in six or eight days more I again visit this yard and cut out queen-cells as before, both from the first lot where the queens were taken out—should there be any—and the second lot, and remove queens from as many more as I find preparing to swarm. Now, by the time I make the third visit I shall find a lot of young queens hatched in the nursery; and the colonies from which I removed the first queens will be in condition to receive and accept a virgin queen, so that I will run in a virgin queen in each colony. All this time I must manage to have a supply of virgin queens on hand, to introduce at each visit until I have gone over the whole yard; and, besides, I have all the other work to do in each yard, such as putting on and taking off sections, looking after the nuclei in which I have many queens fertilized for the market, caging and mailing queens, etc. In this way I can attend to six out-apiaries by going to each once a week. The seventh, being the home apiary of only 60 colonies, I can look after nights and mornings, or as I can best catch the time. By this method I can prevent swarming, and dispense with high-priced help; and, moreover, I am sure that each colony has a young queen in the fall."

"Well, Manum, do you think you can take care of seven apiaries alone?"

"Yes, Henry, I think I *could;* but I expect Fred to help me look after the sections and nuclei, and help other ways."

"What do you propose to do with the queens you remove?"

"I expect to sell a good many of them. As I offer them at a low price, many bee-keepers will avail themselves of this opportunity to introduce my strain into their apiaries. What I do not sell I shall use in making artificial swarms; for I must increase a little—at least enough to keep my number of colonies good."

"Do you think you will secure as much honey by this method as you would by allowing natural swarming?"

"Well, Henry, that is a question I am not fully prepared to answer. But my opinion is, I shall not, and I shall have to work harder myself. But I think, after deducting the expense of hired help, the result in *dollars* will be about the same with one method as the other, in a good season; while in a poor season I can save money by this plan of removing queens."

"What if there should come a rainy day or two—wouldn't that disarrange your visits to the out-apiaries?"

"No, not very much, for I aim to have at least one day's leeway, though I often am obliged to visit my apiaries in the rain; but by having my record-book constantly with me I know every morning just what must be done that day; and as I can, upon a pinch, visit two and even three yards in one day, I can many times manage to avoid being out in rainy weather, because I can work two yards in one day when it is necessary, in order to catch up with my work."

"How do you introduce virgin queens so successfully as you do?"

"I do that simply by rendering the colony hopelessly queenless, as I have stated above, by removing the old queen and keeping all queen-cells cut out until they have neither eggs nor larvæ with which to rear a queen, and then simply run the virgin queen in without ceremony. I usually run them in about the 15th day after removing the old queen, though the time varies from the 12th to the 20th day after, according as I have the time and the virgins to introduce."

"Do you run them in at the entrance or at the top of the hive?"

"Usually at the top. At the time this work is done the sections are on the hives, and I simply raise one corner of the enameled cloth that covers the sections, and let the queen run down among the bees in the sections. This is done so carefully that the bees are not disturbed in the least, and the queen is usually accepted. I introduced over 500 last season, and did not lose over a dozen."

"Would it not be better to give them a fertile queen instead of a virgin?"

"No, Henry, I think not, because such a queen would at once commence laying, and soon fill the combs with eggs, and there would be a large amount of honey consumed in rearing the brood, the bees from which would be useless to me as honey-gatherers, as the honey season would be over before such brood would hatch; while, on the other hand, by leaving them queenless 15 days, and ten to fifteen days more before the young queen commences to lay, makes at least 25 days, right in the best of the honey season, that they are without brood to feed; hence the honey they would have consumed is stored in the hive, and the colony is just as well off (for bees) in the fall as though a laying queen had been given them, because they have a part of July and the months of August and September in which to rear a stock of bees to carry the colony through the winter."

"Have you ever tried other methods to prevent swarming?"

"Yes, two or three of them, one of which I think is practical, and I shall practice it somewhat this season, and I believe it is original with me; and if you are in no hurry I will explain it to you, as I should like to have you try it this season."

"I don't think I had better stop now, as my chicks must be calling me by this time. I will call again in a few days, and shall be pleased to listen to the new ways; so, good-day."

"Why, what is the matter with you? What makes you so lame, Henry?"

"Oh! nothing, only a corn on one of my toes. I have sat here so long that it hurts at first starting off."

"Well, it must be a bad one, sure. You just undress your foot while I get something to put on that will surely cure it. There, I will saturate this little wad of cotton batting with extracted honey, and bind around the toe—so. There, now, dress your foot again, and I'll guarantee that to-morrow you will be thankful for the discovery."

"Well, Manum, you beat all the men I ever saw. I never have visited you yet without getting some new idea from you."

"For any new thought I may give you, or any one else, Henry, I take no credit to myself, as they originate with a higher intellect than my own. I am, like all other mortals, simply a medium through which an unseen force gives to the world these new ideas. Though many of these things I have gleaned from other mortals, through whom the same unseen force has expressed itself for the good of all, yet we should entertain no disposition to keep any good thing from our neighbors." A. E. MANUM.

Bristol, Vt.

[Very good, friend M. I suppose we are to understand by your concluding remark, that, if you should make some valuable discovery in regard to alleviating human suffering, you would not be one of the sort who would want $4.00 each from every man to whom you gave the secret. Here is our hand. Shake! But, hold on! While we are shaking hands cordially over this matter of curing a corn with extracted honey, I fear we shall not agree quite as well on the probability that you can run six out-apiaries, besides one at home, and do all the work *yourself*. If there should not be very much honey, and therefore not very much work to do, perhaps you might get along very well. But suppose we have a real old-fashioned season, where the honey comes day after day, as if it rained down, then where would one man be with six out-apiaries and one at home? When I was in Wisconsin I saw an apiary of toward 100 hives, with the hives so full of honey that the greater part of the bees were crowded out, and lay on the outside and in front. The proprietor said he *knew* the bees were losing their time in the very height of the season; but he had taken out honey all day, and it was then after four o'clock, and he was not going to work any more *for anybody*. I suppose that, in the town of Boscobel, people could be hired to work after supper as well as in other places. I remonstrated with him some, because he was going to let that harvest go to waste because of the lack of a little help. Never mind; we will not argue the case with you. But please tell us, through your notes, how you get along. Many others are interested in this very same problem of hiring help.]

CHIPS FROM E. FRANCE.

THE FLAT BOARD COVER AND ITS SLIDING MOTION.

In March 15th GLEANINGS, page 211, E. R. Root says, at the bottom of the first column, "You know that, when we put a flat cover on a hive, we kill bees if we set it flat down on the square edges of the hive; but with a sliding motion, in the hands of those who use that cover, there is not the least excuse for killing bees." Now, I just want to object to any thing being put on over the bees with a *sliding* motion. If there are bees over the frames, or on the square edges of the hive, that sliding motion rolls them up in bunches and kills them. My hives are all square edged on top, and we use a flat wood honey-board. When we put the honey-board on we use a little smoke to drive the bees down between the combs, and with a brush we brush the edges of the hive clean, and then put the board on flat, and kill *no* bees.

RAPID GROWTH OF BASSWOOD-SPROUTS.

About those basswood-sprouts (see page 223), two years ago I cleared off a yard for a new apiary. About the center of the yard there is a basswood stump two feet in diameter. The first year sprouts grew from that stump ten feet high and 1½ to 2 inches through near the ground. We cut them all off; but last year, sprouts grew again nearly as tall and large. Now, if only two or three of those sprouts had been left to take all the growth from the old roots, I think 10 years would have made a fair-sized saw-log.

ABSURD THEORIES: A GENUINE CHICKEN-STORY.

Again, page 227. J. D. Whittenburg, did the bees eat that wheat? No. What then? Mice. There are lots of false notions about bees. I have heard several men say, that, if bees were short of honey, if boiled chicken be placed under the hive, they would eat it and winter on it. Do I believe it? No. Mice again. My son Newel has just got back from the bee-keepers' convention, and says the chicken story was advanced there as a fact.

Several years ago a man told me he had a swarm of bees wintering on chicken. I went to see it. They had eaten up one chicken, and he was going to put in another. They were in an old box hive, and were a new swarm, and the hive was half full of combs. We tipped it up. Chicken bones were there, picked clean.

"There," he said, "see, meat all gone."

"Did the bees eat it?"

"Yes," he said.

I said, "Let me take the hive down. I want to investigate this case."

I took the hive off the stand and turned it over.

"See, there is a mouse-nest up on the cross-sticks, just at the bottom of the combs."

I put in my hand to take out the nest. As I took out the nest, out jumped a mouse—two or three of them, and away they ran. "See," I said, "mice eat your chicken."

"No," he said, "the bees eat the chicken."

We cleaned out the nest and mice, and cleaned off the bottom-board. This was in the middle of winter. I could see a little capped honey up in the combs yet. I told him I thought his bees would live until about the first of March, and then starve.

"Oh, no!" he said; "I will put in another chicken." He had one ready cooked and cool.

"All right, but let us keep the mice out this time." We put the hive back, put in the chicken, and fixed the hive to keep out mice.

About the middle of March I saw the man in town.

"Well, how are the bees?"

"Oh! the bees are dead."

"How about the chicken—did they eat it?"

"No." And just then he saw a man across the street whom he must see right off.

Now, this man was a bee-keeper, had 20 colonies of bees, and had kept them a long time. He was a man of good common sense otherwise; but he was very superstitious about bees, and had a good many notions just as absurd as his chicken theory.

RENDERING WITH WAX AND STEAM.

In Feb. 15th Gleanings, pages 120 and 121, Mr. F. A. Salisbury gives us an excellent article on rendering wax with steam and acid. I am satisfied that all he says is true, and am glad he wrote that article; also E. R.'s comments about the Dadants. All right; that will do first rate for you chaps who have steam; but how are we poor chaps going to raise the steam? Can a man who makes from 50 to 100 lbs. of wax per year afford to put in steam-works on purpose to render out his wax? Now, give us some cheap way of raising steam, and I am with you.

THAT TRADE-MARK.

Let every tub stand on its own bottom. I want my own trade-mark. If the name of E. France & Son pasted on a package of honey is not a sufficient guarantee of a first-class article, I don't want to ride into market on some other name, and I don't want some other fellow using our reputation. E. France.

Platteville, Wis., March 31.

[If I ever said any thing I felt sure of, friend F., it is the statement regarding the flat board cover which you call in question. I generally slide the cover on the hive, and so do all our boys, and we don't roll the bees up and kill them as you speak of. Of course, we use smoke to drive down most of the bees; but there are always a few there that will run up around the edges. By using a great deal of smoke we can drive them *all* down; but it is cruelty to the bees, and unnecessary. By your plan you have to bother with a bee-brush; but by our plan we use nothing but the smoker. Now, I know that I am not alone. Witness Dr. C. C. Miller, W. Z. Hutchinson, James Heddon, R. L. Taylor, Prof. Cook, and a good many others who might be mentioned, all of whom use their flat cover substantially as I have indicated. With your arrangement, however, I hardly think you can slide the cover on. You have and desire burr-combs, and, of course, it would be impossible to slide the cover with bridges built to the top of the frames and to the cover. With the right kind of top-bars and the right bee-space and right spacing, you do not need to have burr-combs. But you say you want them for the bees to climb up on. Call upon those who do not have burr-combs, and ask them whether they get any less honey than some of those who do. I have investigated this matter quite thoroughly, and I do not believe that burr-combs make any difference one way or the other.

I join hands with you in regard to the growth of basswoods. You know that Doolittle, on page 223, seemed to question my statement that basswood from old stumps would grow large enough in ten years to make basswood lumber. If trees will make such growth in Wisconsin and Ohio, I feel sure they would do so in York State, where the basswoods grow equally thrifty, or even more so. Young trees set out, or growing from seed, will not begin to make such a growth.

The communication by F. A. Salisbury, on rendering wax by steam and acid, was designed for foundation-makers, and those who have a large quantity of wax to refine. The articles in Gleanings can not always hit all classes. For instance, those on wintering are of no interest to those in the South; and those in regard to making foundation are of no value to those who buy the article. Those about extracted honey are of no particular moment to those who produce the product in the comb.

After all, it is not a very difficult matter to produce a jet of steam. Take an ordinary square tin can, and have your tinner attach to it a tin pipe, and let the same communicate with a barrel near the stove. I have tried a five-gallon tin boiler on the stove, and find that it will generate quite a pressure of steam. In fact, it will heat hot a coil of pipes in my bath-room; but the probabilities are that the wax-press and the ordinary methods of rendering wax will answer perfectly well for those who have only a hundred pounds or so.] E. R. R.

[Now, I too want to say a word about sliding a flat cover on the hive. This thing was talked of by patent-right venders more than twenty years ago; and when the hives were *new*, say during the first season, the whole thing worked beautifully. Just visit the same apiary, however, say three years later, then how do the sliding covers work, with every thing covered with wax and propolis—covers and hives, perhaps, warped and twisted? Why, it worked exactly as friend France has said; and I confess that my experience with such arrangements was such that I began to feel bitter and sarcastic toward any one who *talked* about such an arrangement. Now comes the point that makes this difference in testimony. Of late, an *eight-frame* hive is getting to be fashionable. The cover is narrower and lighter than any thing we have had heretofore. Another thing, these boys have gone and banished, or pretty *nearly* banished, the burr-combs and bits of wax that used to daub the covers, tops of the frames, and every thing else. If the hives are made nice and accurate, the bee-spaces just right, and kept so, I begin to have faith that the careful bee-keeper may *keep* his covers and the tops of his frames so clean that he can, even after five years of use, slide the covers on without killing a bee—at least, I hope so. But there will have to be a big reform, I tell you, in a good many apiaries. How many are there who have hives that have been in use for five years, where it is practical to slide the cover on without killing or rolling up bees? Raise your hands, please.

Friend F., I want to congratulate you on your keen, sharp observation and common sense in having exploded that old humbug about feeding bees a chicken. How stupid we have been all these years! Now, is it not possible, that, after the mice had worked in the wheat, the bees also used the bran? The strong moral is, that mice should *never* have access to a hive of bees at all; and stores of sugar syrup are probably cheaper and safer than *wheat*, or *chickens* either.] A. I. R.

PROTECTION VS. NO PROTECTION.

A VALUABLE EXPERIENCE.

Friend Root:—In the spring of 1890 I concluded to test thoroughly the advantage of spring protection for single-walled hives. My bee-yard is laid out in three circles of 50 feet diameter, with a smaller circle within the large ones. The hive-stands holding two hives each, are placed around these circles, 16 on the outer circle, 8 in the inside smaller one. and all facing outward. This is the most satisfactory arrangement I have ever tried, as it gives a distinct individuality to each stand. In setting out the bees in the spring. I selected one of these circles and filled the 24 stands with 48 of my best swarms as nearly equal in quality as possible. I then took lath and made 12 handsome outside cases large enough to set over two hives, with four-inch space on all sides for packing, and six inches on top. I placed one of these cases on every other stand, leaving one half of the hives unprotected. The cases were then filled neatly with excelsior sawdust from the section machine. There were double bottom-boards, and bottom protection to the packed hives. The cases were made in four pieces, so that, by tacking four small finishing nails, one in each corner, the whole case could be knocked down in a moment, and laid away in the flat when not in use; and when the 12 stands were packed in their neat cases, and securely covered with a waterproof roof, I said to myself, "Well, this is just splendid." The 24 other hives were left entirely unprotected, except that each hive was covered with a shallow rim three inches deep, with building-paper nailed on one side for a bottom. Each of these shallow boxes was filled with sawdust. A square of burlap was spread over each hive, the boxes set on these, and covered with a good roof. The spring was excedingly cold and late—just such a one as would give spring protection its best chance to prove its value. I then gave watchful care to all alike, and awaited results with great interest. I resolved at the start that I would let all those bees swarm naturally, and then keep strict account of the time of swarming as well as the honey produced by each class of swarms. They all did swarm somewhat late, as the season was the poorest for honey in all my 45 years' experience.

I will not lengthen this article by giving details of the results of this experiment. It is sufficient to say, that, while the cost of material for making the cases was only 25 cents each, and the work of making them was not very great, yet the increased result was not great enough to warrant this small outlay. I shall try the same experiment with some new ones again this year, and again note results. But my present impressions are, that plain hives, cellar wintering, with spring protection in the shape of warm bottom-boards, and warm covers for the top of the hives, are the thing. The bottom is where the cold enters, and the top is where the heat escapes. Both of these points should be carefully protected. My observation has led me to fear that the danger of enticing the bees to leave their warmly packed hives on unsuitable cold days, and perishing in the cold winds, will counterbalance all the good they will do.

BARNETT TAYLOR.

Forestville, Minn., March 23.

[Look here, B. Taylor. You have given us the result of a very valuable experiment just now; but as you prepared your bees, I am sure they all wintered pretty well; for, in fact, both those that were chaff-packed and those that were not, were in very good good shape for winter. You have omitted to say to our readers that you have them in these shallow half-depth frames; but the fact is, in those shallow brood-chambers, with a good warm bottom-board, and your chaff packing on top, you really have a pretty good chaff hive; and I should not wonder that, with such good protection for both top and bottom, and then allowing the sun to strike directly on the sides of the hives whenever it shines, we shall have an arrangement pretty nearly as good as a regular chaff hive.]

BEE-ESCAPES.

THEIR REQUISITES, USES, AND ADVANTAGES.

During the season now rapidly approaching, many bee-keepers will use the new bee-escapes who have never tried them before. The horizontal escape has passed the experimental stage, and is an accomplished fact; and of its uses and advantages there is no longer any doubt. When I invented the horizontal escape I discovered a *system* rather than any particular form of escape; and when I look over the many catalogues now advertising the "Dibbern" (or horizontal) bee-escapes I often wonder what they are really like. There seems to be a general disposition to simplify and cheapen every thing used in the apiary, and the bee-escape is no exception. Indeed, I expect to greatly simplify it myself the coming season; but past experience has taught me that it is entirely safe to "go slow" in the matter. The pear-shaped escape between metal sheets was entirely successful last year, and I shall make no radical changes till something better, simpler, and cheaper has been fully tested.

I fully believe this to be a great invention, and I want all bee-keepers to have the advantages that it secures; and all are free to make, or buy them where they please; my only concern is, that escapes sent out under my name should be rightly made, and give good satisfaction. With this idea in view, it seems to me it would be well at the present time to give a few of the requisites of a perfect bee-escape.

The first thing required is the escape itself; and it should be so made that it will fit into a board without any projections, and no empty boxes or supers should be required

The next thing is the escape-board, to cut the bees in the super off from the main hive. This should be made of boards not more than half an inch thick, and should be provided with bee-spaces, so that, when it is placed under the super, there will be a bee-space on both sides. The escape should be removable from the board, so that a piece of board can be substituted for the escape when desired. There must be neither brood nor queen in the super, or the escape will not clear it entirely of bees. If a wood-zinc honey-board is used, there will be no trouble on this point. The escape should be made with not too many or too large openings, as the bees are no fools, and readily find their way back through them where there is a fair chance. The escape should also be so placed that there will be no more than a bee-space under it, for the bees to cluster in, for I have learned that, where they can cluster on the cone, they are much more apt to find their way back through it. I have also found that bees can not cluster and hang on to a piece of smooth tin as they do on a wire-cloth cone. If cones are made of wire cloth I would place them on the upper side of the board, with a piece of tin, with small holes punched in it, for the bees to pass out, for the lower side. This is a form of escape I shall experiment with this season. I have many other experiments in view on this line, having no less than a dozen forms of escapes ready to try as soon as there is any chance to test them.

I do not see that there can be any doubt as to the advantages of the bee-escape. It makes it not only easier and pleasanter for the apiarist, but irritates the bees much less than any other method. The escape-board can be slipped under the super in less than a minute, and the bees will escape into the super or hive below, so gradually and peacefully that they do not seem to know what has happened. Cases can be placed over the escapes, and in a few hours the honey can be carried away without disturbing the bees from their work in the least.

The escape is particularly useful in the management of out-apiaries. Last fall, when I got ready to remove what honey there was in the supers at my out-apiary, I found that robbing was "just fearful," as there was no honey coming in; and as I had neither shop nor honey-house there, I hardly see how I could have managed without the bee-escape. I was digging a "bee-cave" at the time; and as I had many other things to look after when out, I had to make good use of my time. When I got out there in the morning I would place these escapes under as many supers as I could haul in my light wagon, and then go about my regular work. When I got ready to go home I would load up my honey, with scarcely a single bee to bother. Once I placed the escape-board under a super that had a small knot-hole in it, that had escaped my attention. A few hours after, I heard the shrill note of the robber, and soon found that the bees were robbing through this knot-hole, there being no longer any bees there to defend it. I fully believe that the escape will prove as valuable for extracted as for comb honey. What we want is to get the "hang" of the proper management. Last year some of our California friends objected, on account of the honey becoming too cold if left over night on hives over the escapes. But, why not put the escapes on in the morning, and at intervals during the day, so that there would be a succession of supers that the bees had just vacated? The sun, which I believe nearly always shines there, would certainly keep them warm enough. Of course, the bee-escape presupposes a super of some kind; and such bee-keepers as remove their honey in single wide frames or sections, like Doolittle, will not find much use for them. It is not strange that all bee-keepers do not take readily to the bee-escape. When we remember that we are not at all agreed as to the advantages of comb foundation, the extractor, and many other things, it is not to be wondered at. All the same, the bee-escape has "come to stay," and many who are now shaking their heads will "come into the agency" by and by.

There is yet another use for the bee-escape besides removing the surplus, that is, in hiving swarms, that promises good results. Last year I tried a sort of combination Heddon-Tinker bee-escape system, that pleased me greatly. I simply hived the swarm on the old stand and removed the partly filled super to it from the old hive. I then put on the escape-board, with escape in place, and the old hive on top of that, giving them a small entrance of their own. I would leave it there for seven days, during which time bees were constantly escaping to the new colony. On the seventh day the old hive was removed to a new stand, and a hive-cover laid on the escape-board, still leaving the small entrance for the returning bees to enter the bee-space under the cover, and escape to the new colony below. To my notion this works much better than the Heddon system, as you are not required to shift the hives every day, and having them standing around in all sorts of awkward positions. Then, too, the bees from the old hive are never at a loss to know where to go, and the old hive is so reduced in bees that the chances of any further swarming are very small. Perhaps there are yet other uses for the bee-escape. Time only can tell.

Milan, Ill., April 1. C. H. DIBBERN.

[Years ago, neighbor Dean and myself rode 20 miles to see a house-apiary all complete and in running order. The thing seemed to work very well, with the exception of the difficulty of taking honey from the bees. During that whole twenty-mile ride we two talked the plan over, with the view of getting the honey away from the bees, without shaking or brushing them off. My neighbor thought it might possibly be done by waiting until cold weather drove the bees out of the supers. He said he didn't believe it could be managed profitably in any other way. I presume such a thing as a bee-escape was at that time used to some extent; but we did not think of it, or did not know one could be made to do the work that they are now doing. Who knows but that bee-escapes may finally revive house-apiaries? I suggest in the A B C book, that one might have a hive of bees in one corner of the pantry, letting them go out through the wall of the house. Then the good wife can take a section of honey right out of the hive, and put it on the table, provided she can get it without *getting the bees also*. Can't a bee-escape be arranged so as to accomplish this?]

RAMBLE NO. 40.

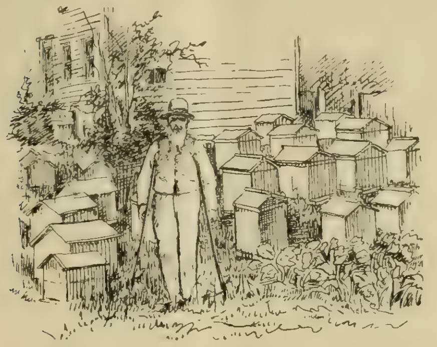
BEE-STINGS AND RHEUMATISM.

While upon my travels I have found many people afflicted with the various phases of rheumatism; and many of the cases that have come under my observation have really been of such a nature as to call out all of my sympathy. Rheumatism that will draw the limbs out of shape, making great knots on the muscles and joints, and inflicting constant and torturing pains, and rendering the patient as helpless as a child, are cases that we can not think of but with sorrow; and in their presence the joke about bee-stings as a cure for rheumatism would not be spoken; for nothing but the divine hand of love could ever make those limbs straight.

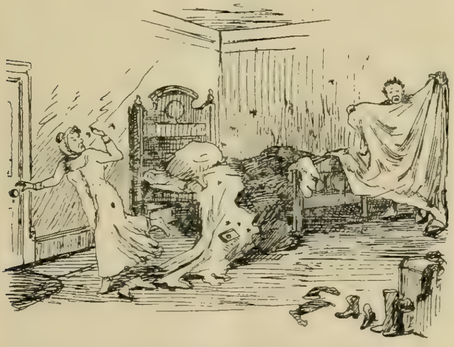
One of these rheumatic cases, who had enough, but not of the severest kind, has been known to the Rambler for several years.

I will, with the aid of the camera, introduce you to Mr. John I. Finch and his apiary in North Greenwich, N. Y. Mr. Finch is a blacksmith by trade, and for many years wielded the hammer industriously in the little shop by the roadside. But rheumatism gradually slackened the blows upon the anvil, and active work was suspended. His attention was thereafter directed to bees, and he now has about thirty colonies, which he thinks is about enough for a man to care for who is obliged to get around to all of his work upon crutches.

Mr. F. has had his ups and downs in the bee-business, having the usual yields and the usual successes and losses in wintering, and, on the whole, for the number of colonies and the disadvantages under which he labors, he has been quite successful. His colonies are run for extracted honey, and, with the exception of a few in chaff hives, they are wintered in the cellar. Though Mr. Finch has manipulated bees for several years, and has been stung an immense number of times, his rheumatism shows no sign of abatement. He had heard so much about the cure of rheumatism by the sting remedy that he has been careful to watch the effect. A few stings have no effect, except the usual smarting and pain; but a large number, in his case, caused nausea, which is not an uncommon feeling with those having no rheumatism. Mr. F. said that the sting of a single white-faced hornet is more effective than a dozen bee-stings, and he attributed it to the depth to which it is plunged, and thinks that *Apis dorsata*, or some bee with a sting that would penetrate half an inch into the flesh would possibly effect a cure. A bee-sting, he thought, might cure a local rheumatic pain, but his case was over too much surface to be thus affected.

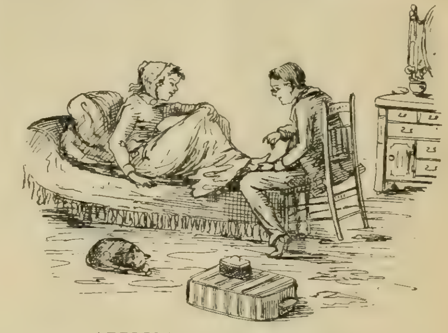


JOHN I. FINCH AND HIS APIARY.



BEE-STINGS AND RHEUMATISM; THEIR APPLICATION AT BED-TIME.

After studying Bro. Finch's case, several others came to mind. A friend was greatly troubled with local rheumatism under the shoulder-blade; but after keeping bees a few years the rheumatism disappeared entirely; and, though the stings were never applied directly to the spot, he sang the praises of bee-stings at all times and on all occasions, claiming that it was only necessary to get the poison into the circulation. Our neighbor's wife, hearing of this remarkable cure, sent to the Rambler for bees in midwinter. Remonstrances against disturbing the bees at this time were of no avail; and seeing it was a case of life or death, the bees were procured and placed in a cage, and directions given to apply one at a time upon retiring. As usual, directions were not followed, and the whole dozen were let loose at once. From accounts received from the family next day, I make the following sketch; and if not literally true, it must approach it, from the nature of the elements employed. The next day she sent for Warner's Safe Cure.



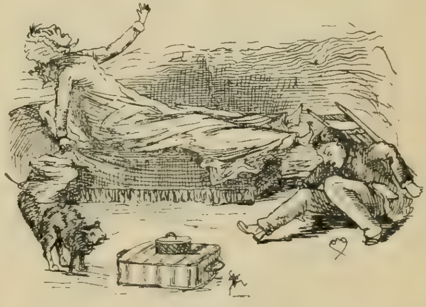
APPLICATION OF BEE-STING.

Another case reported is where a lady who was afflicted with rheumatism in the foot. She had read Jno. Nebel & Son's advertisement in relation to their rheumatism bees, and, having nothing else to think about, a neighboring bee-keeper was sent for, and anxious inquiries were made about the qualities of the Nebel bees over others for the cure of rheumatism. The neighbor argued that his bees were just as powerful as Nebel's; "And," said he, "a sting is a sting, whether in Mexico or Canada, or on High Hill, Mo.; and to prove it I will run over and get a few bees and cure your rheumatism."

The bees were produced; and the patient, being nervous at the approach of the test, timidly asked the neighbor whether the sting of a bee hurt much.

"Oh, no!" said he jocosely; "just a little smart, and all is over. Just keep calm. My bees are just as good as Nebel's."

The application was made, and the result, as the sketch will show, was highly satisfactory to all parties concerned, and has not ceased to be the talk of the entire neighborhood, even unto this day.



RESULT.

I am happy to see, however, that Bros. Nebel have dropped the rheumatic attachment to their advertisement this spring, and it is fortunate they did: for it stirred up a terrible rumpus among the nervous rheumatics; and, as far as learned, but little good has been accomplished, and the cure of rheumatism by the application of bee-stings is a skeptical point with the

RAMBLER.

[But, friend R., why didn't you tell us whether the bee-sting cured the woman's rheumatism or not? The picture tells us all about how your neighbor got piled up in a heap; but after things were restored to rights, the cat soothed, and the bees had got out of the room, was the rheumatic ankle any better, and did she look happy and thankful, just as she does when the application was being made? It is true, you say, in a sort of general way, in your concluding sentence, that you are skeptical in regard to the whole matter, and may be that is intended to answer the question.]

CHIPS FROM THE FEB. 1st NUMBER.

BY WOODCHOPPER.

R. M. Reynolds is right. Queens will lay in supers just as soon with 2-inch sections as with 1¼. I have tried both.

Bait sections (page 83) may prevent A. C. Tyrrel's from swarming, but they don't have any effect that way on mine.

Tell Rambler to go ahead and develop the best bee (see page 83), and the rest of us will be ready to help reap the results.

Yes, Quinby did invent tin combs, but the bees would not use them. They were not ready for metallic caskets then. Are they yet?

Dr. Miller, why are bees better broodless in February? Nature sets queens to laying shortly after Jan. 1st, sometimes sooner. Doesn't she know what's right?

WIDTH OF TOP-BARS.

You are right about the width of your top-bars, but I would space an eighth further apart. I have used thousands of them, and they go in and out much better.

EXTRACTED HONEY FROM DARK COMBS.

Dark combs do affect the color of the honey, friend Andrews (see page 98), if it remains in them long; and if bee-bread is stored in them it will make the honey rank.

LEATHER APRONS.

Tell Emma Wilson to make aprons of leather, as a blacksmith does; and it would look all right for E. R. too; and light calfskin makes the best glove. It must be smooth, or bees will sting through it.

SHINGLES FOR HIVE-ROOFS.

These are much the best of any thing I ever tried, costing less than any other good roof, and making a neat job. They will last 20 years or more, according to quality. Tin lasts well; but it gets so hot if the sun shines on it that it makes a regular furnace of the surplus arrangements under it.

OUT OF THE BUSINESS.

J. T. Fletcher, page 97, is liable, with some others, to find himself out of the business some fine spring morning, as I have seen a number of others do. When we have a really severe winter, the chaff hives will winter bees, and the outer cases will prove failures. The last three winters have been no real test.

HONEY FROM KEGS OR BARRELS.

I never saw any first-class honey come out of a keg or barrel if it had been there any length of time. It is much better in tin cans. Perhaps the New Yorkers prefer their honey half soured, which it is pretty sure to be in wooden packages. I have several times bought honey in kegs and barrels, but I never got any that was really fine.

CLOSED-END AND HOFFMAN FRAMES.

I used closed-end frames 15 years, and I like them first rate; but I discarded them for hanging frames because they were not good to winter in on summer stands. I did not use them inside of a hive, but let them form the ends of the hive. There was no trouble about propolis; and for interchanging they can not be surpassed, if they are made right so as to space 1½ inches apart.

PAINTED MUSLIN VS. SHINGLES.

I tried painted muslin on a few hives some years ago, but it was not worth the cost. It lasted about six years. So far as the muslin is concerned, it doesn't cost very much; but, oh my! as Uncle Amos sometimes exclaims, what a lot of paint and time it took! I had to paint about six times before I got them water-proof; and a gallon of paint would cover only about two hives—just the roof.

CLOSE SPACING, ETC.

Say, friend Scothan (page 100), do you charge your good yield of surplus and heavy hives for winter to close spacing? or did the clover and basswood pan out better than ours? and that nice field of buckwheat, didn't it help to make the hive heavy in the fall? If the close spacing did it, we'll space up tight after this, for we got no surplus, and some of the bees didn't have any thing to winter on, and we had to double up and feed, etc.

SELLING SECTIONS BY THE PIECE.

Friend Whitlock, that is a sharp trick of the grocer, buying by the pound and selling by the piece, and so make two profits; and are we as producers going to allow it? First, we have to buy more sections, put in foundation, then it is more work to crate them; and when we are done, what are we but partakers of other men's sins, for most of them sell them for pounds? That little shortage in weight is the reason they don't want to weigh them. Isn't it time to call a halt before we all get to selling short-weight goods?

SPRING DWINDLING, AND THE CAUSE.

I think E. S. Fowler, of Bartlett, O., is partly right about spring dwindling. There is another cause more frequent. It is this: When we have a long cold spell of weather, say two months or more of downright hard freezing, then, unless the bees are in warm hives, their constitutions are used up in the endeavor to keep up the necessary heat in the hive; and if they don't succeed in it they get cold and go into dysentery, which I call "cold-weather dysentery," and very different from that caused by poor honey, but nearly as fatal, as they die off as soon as they begin work in spring, simply being worn out by being obliged to fire up so much in cold weather.

REMEDY FOR BLACK ANTS; HOW TO GET RID OF 'EM.

If they are the large ones, get a cent's worth of tartar emetic and mix about a quarter of it in a little honey (about an ounce or two), and place in their haunts. After they have eaten it you will see no more of them for about three or four months, when they will begin to come back. A second dose has cleared our house for three years. It will not work on the small ants, for they won't eat it; and if the coal tar (page 101) will clean out the small kinds, then with both you can be "ant clear," both in the hives and the house. This recipe came from the *Housekeeper*, Minneapolis, Minn. Don't let the bees eat it, for it may lay them up till the harvest is over.

THE WILEY CANARD.

I should have supposed that our friend Prof. Cook would have known that he might expect to raise a buzz of indignation at a convention of bee-keepers by giving that wiley (liar) a chance to put himself on record against the honey interests again, and then he goes to apologizing for him, and says he has done lots of good in other departments of science. He will never be able to undo the mischief he has done the bee-keepers of America, even if he lives to be 100 years old. The story of the machine-made comb honey is still traveling. Only three months ago I went into a grocery in a neighboring town, and the proprietor said he was selling honey made without the aid of bees; and when I asked him where he got it he said in Cleveland, and of a certain commission man, naming a well-known honey-dealer. He said that said commission man told him that the honey was not bees' honey, but manufactured by machinery; and he took it all in dead earnest, and told his customers the same story, and it took a good deal of talk to get the idea out of his head; and then I could see that, like the tree that is dug up, the small roots were still there, ready to come up again as soon as the weather was favorable.

Now, if this does not find the way into the waste-basket, I may send another basket for the next fire if chips are good kindlings.

Woodchopper.

[Well, well, Mr. Woodchopper, if you can do as well as this every time we hope you will send us more baskets of chips. They are too good for kindling-wood.

Never saw any good honey from kegs and barrels? What were the barrels made of, and what had they previously contained? Cypress kegs, and oaken alcohol-barrels give no taint to the honey—at least, so say some of the large honey-producers.

We are glad to get your testimony in regard to painted muslin; but there are some of the other bee-keepers who say the muslin is good.]

E. R. R.

[And I, friend W., want to say that I really felt glad to find some one with large experience and good sound judgment to so entirely agree with myself on so many points. Let me correct you, however, in saying that bees would not use Quinby's tin combs. They used them right along, and no fault was found with them except expense, that I heard of. It is true, the bees did not winter in them; but, you see, when the boys weighed the hives to see how much honey the hive contained, they forgot about the metal, and did not calculate; therefore, long before winter was over, the bees had lots of tin but not a drop of stores in the tin cells.—My experience with kegs and barrels is exactly like yours; also with painted cloth for covers. Shingles are too heavy and untidy for hive-roofs.]

A. I. R.

THE PROPER TIME TO SPRAY TREES.

BY A FRUIT-GROWER AND BEE-KEEPER; VALUABLE HINTS ON THE SUBJECT.

According to my promise to you on my way home from the Albany convention, I will write an article on the above topic. I thought it would be of most benefit appearing on the 1st or 15th of April, as May is the month in which we do the most of our spraying.

The first thing to learn is the habits of the insects we wish to destroy. Apple-trees are sprayed to destroy the larva of the coddling moth. The moth deposits her eggs in the calyx of the apple, or blossom, from about the falling of bloom until 10 or 15 days after. The larva hatches in a few days, according to the temperature; and, if not killed, it begins to eat its way into the fruit. About three or five days after blossoms fall is the best time to spray, and continue so doing for about 20 days, as often as rain washes off the poison. If, after the first spraying, it should not rain for a week or ten days, you will kill 75 per cent of the larvæ.

The curculio does not attack the plum until the fruit is about the size of peas, which, in ordinary weather, is a week or ten days after the blossoms fall. Spray plums the same as apples; viz., with Paris green, at the rate of 1 lb. to 200 gallons of water, applied with a good spraying-pump. Some use the same proportion of London purple on apples; but it should be avoided on all *stone fruits*, as it is liable to injure the foliage.

You will see by the above that it is time and material thrown away to spray trees while in bloom; for, nine times out of ten, the rain will wash away the poison before the larva is on hand to eat it. I have my doubts whether bees can be poisoned in this way. I "don't know" that it will *not* kill them. With such a delicately constructed tool for collecting nectar, I think it highly probable that they can gather what they want, and reject the poison. Paris green is insoluble in water, and I think the bees can easily leave it in the blossoms, and take the nectar. I have heard of several cases of bees being poisoned in that way, but was not satisfied with the proof that spraying caused their death. My apiary is mostly under large apple-trees, and I always spray, just as though they were not there. The poisoned water will stand on hives, alighting-boards, and grass; and if the day is a warm one, I always see a great many bees sipping it, and have never noticed any bad results. I have imprisoned bees loaded with such water, for 24 hours, and they came out lively. Those writing upon the subject should not say, "Don't spray while in bloom, for it will poison the bees," but strive to satisfy people that, by so doing, they will throw time and money away; and if you do satisfy them to that effect, why, that ends it. In other words, show them, not how it will injure *other* people, but themselves. I live in one of the greatest fruit-growing counties of the United States, and I know of but one man who sprays his trees while in bloom, and he wants to kill the moth that lays the eggs, instead of the larva from the egg. The mature moth does not eat either the foliage or the fruit, and I hope we shall make him see it soon. I have yet to find an entomologist who recommends spraying trees while in bloom. We have arrived at a point in fruit culture where we have got to use insecticides and fungicides intelligently, or give up the business. As bee-keepers we must lose no opportunity to educate fruit-growers in regard to their own interests, and by so doing further our own. I raise both fruit and honey, and never lose an opportunity of speaking a good word for both pursuits, and showing their dependence on each other when at our farmers' club meetings, agricultural institutes, county fairs, or elsewhere.

G. H. Ashby,
Sec'y Orleans Co. Farmers' Club.

Albion, N. Y.

HOME-MADE HIVES.

HOW TO MAKE THEM CHEAPLY.

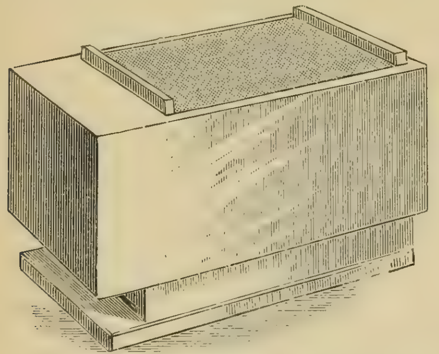
I think I saw a notice somewhere in Gleanings of a dovetailed hive some one was offering cheap made of ⅜ lumber. The editor was afraid it would be "too thin," but I rather like the idea. Being made dovetailed, it would be strong enough; but its strongest point would be its cheapness, for I believe the time has gone by when bee-keepers can afford expensive hives. But if the price were the same. I should still prefer them made of thin lumber, say ½ or ⅝ inch. Flat covers of ⅜ and ½ inch lumber are much the best, as they are lighter. and keep their place better, as I have proved in actual use for several years; and this brings me to my subject of

HOME-MADE HIVES.

I make hive bodies, bottoms, and covers, instead of buying, preferring to put money into foundation, as good straight worker combs and sections filled *full* of foundation, I believe, pay every time. I also buy my brood-frames. sections, and supers. The materials are boot and shoe boxes, generally ½ and ⅝ inch in thickness. The best boot-boxes are 3½ feet long, and will cut two lengths of hive stuff, while shoe-boxes are short and will cut but one length, leaving short pieces that will work in crosswise in making bottoms. The boxes can be bought here for 10 and 5 cents apiece for long and short ones. The short boxes, if in good condition, will each make a one-story hive with bottom and cover, and the long ones a two-story hive for extracting. The ends of the boxes being thicker, they are used for ends of hives, rabbeting them for the hanging frame. A rabbet-plane can be bought for 50 or 60 cents; and some little strips can be nailed on so it will cut just the right width, and stop cutting at the right depth. Of course, the stuff

NEEDS NO PLANING

unless you want to plane off the stencil-marks. For my part I rather like to see them; for the slight trace of the letters showing through the paint reminds me of *money saved;* and I take pride in saying to visitors, "See that hive? I made it myself, and it cost me only *five cents* out, except the paint." When I first made them, six or seven years ago, I made them like the Heddon-Langstroth, with tight bottom; but I now make them with Dr. Miller's reversible bottom, so as to have upper and lower stories interchangeable.



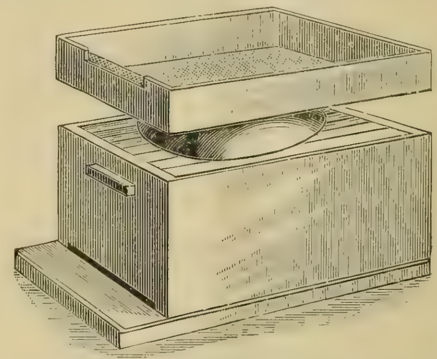
A HOME-MADE BEE-HIVE, MADE OF SHOE-BOXES.

THE COVERS.

These are made of the sides of boxes which are matched. They are made long enough so they can be reversed, and the bees propolize the joints so they will shed rain. They make a light handy hive for carrying in and out if wintered in the cellar, but I have wintered in them on summer stands with excellent results since 1884, by the following mode of packing for winter: The bees are supplied with six frames containing their stores, with a dummy or division-board on each side. Corncobs are laid crosswise over the frames, instead of the Hill device; but latterly I use the large-sized wooden butter-dishes turned bottom up over the cluster, and I like them much better. A piece of burlap is spread over, and then a thing I will call

THE HILL TRAY

is put on (see cut). I learned the use of this from Mr. Hill, of Mount Healthy, Ohio, when visiting at his home in the fall of 1884. It is simply a light rim five or six inches high, with burlap tacked on for a bottom. He explained that it would fit up in the corners better than a cushion. He used them on old-style Langstroth hives. I find them cheaper, too, as they take less burlap.



SHOE-BOX HIVE, WITH BUTTER-TRAY AND TRAY WITH BURLAP BOTTOM FOR WINTERING.

After covering the bees with this tray about two-thirds full of chaff, a five-cent shoe-box is turned over the whole. It comes down over the hive usually two-thirds or three-fourths the way down, and so protects the hive a good deal. They are always longer than the hive, so they are put up close behind, and left sticking over in front. This gives a chance for ventilation through the hole covered with screen in the front end of the tray. It will be seen that this makes but little additional expense in preparing the bees for winter, and but little packing material is used. One thing I will mention that I consider essential to success in wintering outdoors in this latitude, and that is—*old combs.*

Oberlin. O., Feb. 21. Chalon Fowls.

•

[Hives made of thin stuff had a run some 20 or 25 years ago. They were discarded because they were so liable to injury, and most of us thought they were not as efficient protection against the frost as hives made of inch lumber. Some 12 or 15 years ago I revived the idea again with what I called the "hoop" hive. These had covers ⅜ inch thick. But every little while somebody would sit down on these thin covers, and smash them in. They also troubled me by getting split and coming to pieces. I decided that they were not as good weather protection, either in winter or summer. I have made some very pretty bee-hives from boxes bought at dry-goods stores; but unless one has much spare time to pull them to pieces and get the nails out, and considerable skill and ingenuity in making things work together, I decided it did not pay. Now, in contrast with the above, I have several times thought that thin hives, sitting right in the sun, work better, especially in the spring of the year, than thick ones. Such hives will certainly answer very well, for many of us have tried them when we could not get any better.]

BIOGRAPHICAL.

JAMES A. GREEN.

> Seest thou a man diligent in his [bee-keeping] business? He shall stand before kings; he shall not stand before mean men.—PROV. 22:29.

James A. Green, the subject of this sketch, while still in his teens decided to make the road leading through the apiary his royal road to fortune. Giving to his chosen profession the close study and hard work always necessary to make a success of any profession, bringing to it the stimulus of a decided taste for bee-keeping, and a natural aptitude for its details, he is likely, before he is much older, to find "plenty of room at the top."

Mr. Green was born about thirty years ago in the little town of Dayton, on the banks of Fox River, in Illinois. While he has built up an extensive business and quite a national reputation among bee-keepers, this town always has been and continues to be his home.

JAMES A. GREEN.

His practical experience with bees began in 1878, during the absence of his father, who was at that time a bee-keeper on a small scale. Swarming-time came on, the colonies needed attention, and James and his mother stepped promptly into the breach. All went well with the experiment; and when Mr. Green returned from Colorado the boy had found his vocation.

He began with twenty swarms in old-fashioned box hives. He found it hard to gather information about his new business, and, for lack of this knowledge, carried it on for some time in a primitive way, which the modern bee-keeper would consider very antiquated indeed. But James was a very determined boy, and he did not believe there was any need of standing still or going back because the way ahead looked rather difficult. So he diligently read on, gathering from books and magazines some knowledge, and a little insight into the ways of bees. At last, in the A B C of Bee Culture he found the solution of his difficulties, and the best and strongest of foundations for a novice in bee-keeping to build upon. The A B C of Bee Culture very wisely assumes that the beginner knows as little about his future work as the child does of written language. So he, like the child, is required to begin with the alphabet, and when he has gained a thorough mastery of this he is also a long way on the road to the mastery of the bee-profession.

James learned his A B C's thoroughly, and henceforth his upward path became comparatively easy. "Progressive and determined" make a very good combination, and this boy had both qualities. Gradually the old-fashioned methods and appliances gave place to new, improved, and scientific ones. The ingenious hand of the master of the bee-yard supplemented his tools with handy contrivances of his own, and the apiary grew and grew until now, 1891, it numbers 300 colonies, and the sale of its product goes to many of the great cities of the country.

More than this, while Mr. Green is still, and always will be, a student, his knowledge of bees and their culture is so wide, accurate, and practical, that he takes rank among the best authorities in these matters. His name was recently sent in by the secretary of the Smithsonian Institute for admission to one of the great scientific societies of France—a high honor for so young a man who has been only eleven years in the work.

Back of every good man is a good mother. Back of nearly every successful man is a sympathetic mother or wife. Mr. Green is not an exception to this rule. From their babyhood, Mrs. Green took an interest in all that her boys cared to do — an interest no less wise and thoughtful than it was devoted. Each boy felt that mother was his particular partner, giving an intelligent appreciation to all the details of his boyish plans for the future, and sympathizing with all his ups and downs. When Frank, the chemist, hid his beloved bottles on the high shelf of the dining-room cupboard, mother did not scold, nor ever ask to have them taken away. She only told Frank to be very careful how near he placed them to the eatables. When Kent, the bookworm, buried his face in the dear volume, and shut out all the world beside, she found out what he was reading, and, just as much as her busy life would allow, read with him. When Jimmy began to work among the bees, she armed herself with veil and gloves, and went with him. And she has read so intelligently the books and magazines concerning the honey-bee—she has studied so carefully its habits—that she is very good authority on the way of making it profitable to its owner. So that it is certainly true that Mr. Green owes much of his present standing in the profession, and his success financially, to his best friend, his excellent mother.

Mr. Green is not a man of one idea solely, nor does he believe in moving in the rut of one's own business. As an extensive and successful bee-keeper, he has been honored by his brethren with the vice-presidency of the Northwestern Bee-keepers' Association, and it is needless to say that he fills the office well.

A justice of the peace in his native town, his office gives him the power to bind in one two loving hearts.

A graduate of the Ottawa High School, he has supplemented an excellent education by a course of careful and valuable reading. A lover of, and also a judge of first-class poetry, Mr. Green has many an apt quotation at his fingers' ends, and he gives them on suitable occasions with point and grace.

This love of choice and thoughtful reading led him very naturally into the Chautauqua Literary and Scientific Circle, of which he is a very faithful and conscientious member. He belongs to the class of 1892, and has for some years been the president of the Ottawa Laurels (C. L. S. C.). Mr. Green is an enthusiastic amateur photographer, delighting in flash-light pictures, in which branch of photographic art he has made some good hits, and is marching onward to perfection.

Best of all, he is a quiet, earnest, working, every-day Christian; a member of the Congregational church in Ottawa, and president of the Young People's Society of Christian Endeavor, he is letting his "light shine before men."

Take him all in all, and viewed through the medium of other eyes more impartial than those of a cousin, James A. Green, besides being a live, progressive bee-keeper, is undoubtedly a very nice young man. LYDIA STRAWN.

Ottawa, Ill., March 18.

[My good friend, we feel greatly obliged to you for all these things you tell us about our valued contributor James A. Green. While much of it is new, we long ago decided here in the office that friend Green was a young man of no ordinary merit and acquirements. In fact, he now stands among the chosen few whose copy goes straight to the printers without reading. But, my good friend, will you pardon us if, while reading the above excellent encomium, our thoughts would keep wandering from the subject of the discourse to the discourser herself, especially when you speak with such touching pathos of the part the *mother* plays in this great machinery of human affairs and human events? It was *my* mother who first took me by the hand and led me to the garden on the hillside, and taught me to look for the beets and radishes that were just peeping out of the ground. Then she led my thoughts to Him who holds all these things in the hollow of his hand. She also led me to the bee-hives, little dreaming, perhaps (like many another mother), of what the outcome would be. If it were anybody else than friend Green, such kind words might be apt to make him proud; but then, you know, he is a working Christian. Who can tell all that is compassed and comprehended in these two simple words, "working Christian"? May God bless the words of this short sketch; and may they prove an inspiration, not only to the *boys* and *young men*, but to the *mothers* of our land, young and old.]

POISONOUS SNAKES, ETC.

SOME "SNAKE STORIES" BY PROF. COOK.

I am reminded by subscribers for GLEANINGS that I have not yet written the promised article on poisonous snakes, and so I will defer it no longer, especially as it is a subject of unusual interest to all.

As is well known, we had, thanks to GLEANINGS and its readers, several rattlesnakes last summer in confinement and under observation, and with them we had two or three copperheads and one highland moccasin, or cottonmouth. These snakes are very interesting, as being justly the most dreaded enemies of man. Their concealment, readiness to bite, and the terrible nature of a wound from their fangs, make them peculiarly interesting.

All of our poisonous snakes have broad, flat, triangular heads, and two curved movable fangs in the upper jaw. These are either hollow or grooved, and connect with a poisonous sac in which is stored the venomous liquid which is so much dreaded—justly dreaded—as it is a deadly poison. This is said to be safe if taken into the stomach; but once introduced into the blood it brings severe pain, paralysis, and death. When a venomous snake strikes, it straightens its fangs at the same time; and the same muscles that raise the head and extend the fangs also compress the poison-sac, and extrude the poison. It is said by some authors that the snake may strike without extruding the venom. I do not know that this is not so; but I do know that they often throw drops of poison when they strike, even though they may not bite at all. Last summer our moccasin would strike at a stick, and we often saw the venom fly, and also saw drops of poison on the stick.

In the form of the head and structure of the biting apparatus our poisonous snakes are like the same of the Orient. But all *our* poisonous snakes have a deep pit on the outside of the head, between the eyes and the nasal opening or openings of the nose. This pit is absent in the venomous snakes of the Old World. Our poisonous snakes, then, are easily known by their broad, flat, triangular heads, movable poison-fangs, and the pits between the eyes and opening of the nose. These are the only ready means to distinguish the copperheads and moccasins, while the several species of rattlesnakes are further marked by the conspicuous rattles that adorn their tails. These rattles are simply overlapping ring-like scales, which are connected some like the swivel link of a log-chain. The rapid vibration of the snake's tail causes these scales to move on each other, and produce the peculiar whirr which gives the common name to these venomous reptiles. It is a very curious and interesting fact, that the copperhead will vibrate its tail against a board, stick, or box, so that one could scarcely distinguish it from a real rattlesnake. We noted that specially last summer.

The only poisonous snake we have in Michigan is the massasauga, or prairie rattlesnake. This is short, heavy, dark in color, and beautiful neither in color, form, nor habit. Usually this snake, like the other venomous species, coils when it strikes, but not always. It will strike if circumstances prevent its coiling. The young of our massasauga are born alive—that is, the eggs hatch within the mother. Such snakes are called ovoviviparous or viviparous. I think all of the venomous snakes are like these in their reproduction. The young massasaugas, when very small, will run, as I have witnessed, when danger threatens, into the mouth of their mother. It hardly need be said that they seek a very safe place.

Rattlesnakes are grouped in genera from the peculiar arrangements of the plates on the back of the head. Thus our massasauga belongs to the genus *Candisona*. It is *C. tergemina*. There are two other species of this genus in the southwest of our country.

The rattlesnakes of the East and South are longer, slimmer, and handsomer than the massasauga. The large eastern one is *Crotalus horridus*, and is aptly named. They vary from yellow to black, and are marked with spots, so that often they are quite handsome. They may grow to be four feet long. There are several species of this genus in the South, Southwest, and West. One, *C. adamanteus*, or diamond rattlesnake, is very handsome. We had several from the Gulf States last season, and they were beautiful. The color is yellowish brown, and they are ornamented with thirty or more dark-brown diamond-shaped spots. They are slim and graceful, and are objects of great beauty and interest as they strike—that is, if removed at a safe distance from the observer. One of these bit a cat in my laboratory last summer.

The poor cat seemed to be in terrible pain immediately, and in less than two minutes her hind limb—the one bitten—was so paralyzed that she dragged her hind parts. She was in such terrible pain that we gave her chloroform and placed her beyond suffering.

The copperhead is also a handsome snake. It is light reddish brown, spotted with darker brown, and has a copper-colored head. It seems less brainy than the rattlesnakes, for it would strike, or strike at, a stick, and throw its poison, while the rattlesnakes could not be fooled in any such way. They would attack only real game. The moccasin, like the copperhead, was easily tantalized to strike at a stick. It is darker, and not so handsome as the copperhead and diamond rattlesnake.

From our experiment with the cat I can not but believe that these snakes are fearfully venomous. Were I bitten, I would adopt radical measures to effect a cure. If on the hand, finger, arm, or leg, I would tie a string very tightly above the place, and try to keep the poison from entering the circulation. If I could get a hot iron, or some acid, at once, I would cauterize the wound; but it would not do to wait any. Sucking the poison out would always be in order. This is safe, for, as we have seen, no harm would come, even if some of the venom were swallowed, though this would be unnecessary. The advice to drink whisky freely is so stoutly urged that I have only to say that it *may* do good.

THE CHAIN, OR KING SNAKE.

I am indebted to one of your Georgia subscribers, Mr. J. F. McCord, Covington, Ga., for a beautiful chain-snake. This, one of the commonest snakes of the South, is also called king-snake, and Mr. McCord refers to it as the pilot-snake. The scientific name of this handsome snake is *Ophibolus getulus*. We see it belongs to the same genus as the common milk-snake of both North and South (*Ophibolus triangulus*), which it much resembles in form. It is also about the same size, from 25 to 40 inches. This milk-snake is often called house-snake, as it is not infrequently found in cellars and outhouses. Both of these snakes are entirely harmless.

The chain-snake is jet-black, and ringed with narrow yellow lines which fork below, inclosing black spots. Below it is white, spotted with black. The intense black, lined with yellow, gives a remarkably pleasing combination, which, together with the slim elongated form, makes this one of our very handsomest snakes. The negroes are said to regard this snake with respect, and even awe. They claim that it rules the reptile world, and will even attack and subdue the terrible rattler. This is doubtless why they call it the king-snake. The chain-snake feeds on lizards, mice, and other snakes. Like our milk-snakes, this is entirely harmless. It can not do harm, should it attempt to bite; and the probability is, it would never essay to bite. The many teeth, projecting from the jaw and somarine bones, are too weak to do more than hold on to its victim as it attempts to swallow its live and lively food whole. These teeth point back, and so make every struggle of its prey help on the operation of swallowing. I am very glad of this specimen, as I always am to receive specimens from the South. I will always gladly pay express, and shall be very grateful for new specimens.
A. J. COOK.

Agricultural College, Mich.

[Some little time ago one of our correspondents asked to have his GLEANINGS discontinued because it was too "snaky." We think, however, that no one will complain in this line after having read the wonderful facts which Prof. Cook gives us. They are all the more interesting to me because I know they are *true;* but if it were almost anybody else than our careful friend, I might be a little suspicious—especially in regard to that startling statement that the young seek refuge in their mother's mouth. Now, I am just Yankee enough to want to ask a lot of questions. Do not snakes breathe? If so, how are those young chaps going to breathe when the mother has swallowed them? and does she swallow half a dozen or so at once? After the danger is past, I suppose they turn around and crawl out again. Do they hold their breath all this time? I have heard this statement before, but I did not believe it. Our proofreader suggests, however, that you only say they find refuge in their mother's *mouth*. But, dear friend Cook, do you mean to say that the mouth is large enough to give place to a brood of young snakes? The story was told me that she swallowed them to give them a place of safety.]

THE NOISE OF BEES IN THE CELLAR.

DR. MILLER DISCUSSES THE CAUSES.

I wish I could clearly interpret what the bees mean by the noise they make in the cellar. Do they make the same kind of noise at all times? Does a noise *always* mean that something is not quite right? I have thought that, when bees are making a noise because too cold, they make a kind of sharp, rattling noise, different from the noise made when they are warm. Perhaps others can tell better about it. This rattling noise must be made with the wings, for bees have a true voice, aside from the noise made by the wings. Cheshire says the wings make the buzzing, and the humming is made by the interrupted air passing through the spiracles, or breathing-tubes. This latter is the true voice. Landois recognizes a third tone in the flight sound—that made by the vibrations of the abdominal rings. Differently from what might be supposed, the most acute and intense noise is that made by the true vocal apparatus. These three tones are all made at the same time during flight; and, if I understand the matter rightly, they are inseparably connected with the muscular effort made in flying. We all know very well the difference there is in some of the sounds made by a bee on the wing as it leaves the hive or returns heavily laden, or flies scolding about our heads.

Now, does a bee, or can a bee, make the same variety of sounds in the hive as on the wing? When a colony of bees in the cellar are as quiet and still as if dead, and are disturbed, they always seem to me to make a kind of sleepy sound. If a colony is too cold, it makes a noise. Does the noise make it warm? Hardly. On a cold day a man slaps his arms around him to warm himself. The exercise warms him, and the noise he makes is a necessary accompaniment. Isn't it just the same with the bees? But if the bees get *too* warm they make a noise. Surely, exercise doesn't cool them, does it? If you get too warm, do you go to jumping around or slapping your arms together to cool off? Well, you may use a certain kind of exercise to cool off, and that is by plying a fan—precisely what the bees do, only I suspect that, generally, the only feeling they recognize is a desire for purer air. Dzierzon intimates that the main reason why bees are noisy in cellars is because of impure air. If cold, do they ever get *very* noisy? But when warm, they do get very noisy.

It is generally believed, and I think it is correct, that, in summer, bees keep the air in their hives pure by ventilating, and it is the same, I suppose, in the cellar. That ventilation is always accompanied by a certain amount of sound, is it not, whether in summer or winter? If the bees recognize the presence of impure air in the hive, the natural thing is to ventilate. If the air in the hive is exactly the same temperature as that outside, and there is nothing to create any motion of the air either in or out of the hive, then, as the air becomes impure by breathing, the bees must necessarily purify it by ventilating. If, however, the air outside the hive is enough colder than that within, the greater weight of the outside air will make it displace that within, so that, if it be just enough colder, there will be no need of action on the part of the bees, either to get up heat or to purify the air. That particular point of temperature is supposed to be somewhere in the neighborhood of 45°, possibly a little above it. This is on the supposition that the air outside the hive is pure.

Now, suppose a colony gets to work ventilating, and the air they introduce is just as impure as that driven out. The effort to change the air will become more violent, until the whole hive is in a roar; and, if the cold does not force them to stay in the hive, they will collect on the outside, just where their instinct tells them they may find the purest air. Just this state of things I have seen many a time on warm, muggy days toward spring. On the evening of such a day, I have opened wide the cellar-door, so as to let in better air. Did that quiet the bees? So far from it, the noise increased so much that the roaring could be heard at a distance of several rods from the cellar. Why? Perhaps the bees had understood that a stock of fresh air had been brought into the cellar, and that now it was worth while to work harder than ever to get some of it while it was going. At any rate, they seemed to go to work with a will; but when they had filled their hives with the precious breathing material, they stopped ventilating; and by the next morning the cellar was almost as quiet as death, and not a bee would stir from the hives, though the full light of day streamed in.

So far, then, we seem to have noise of two kinds—that made when the bees are warming up, and that made when they are ventilating. The noise of cold bees seems a little in the cellar like the sound of a soft wind blowing through the pine-trees. Are there any different sounds?

Are we to understand that, when a colony is somewhat noisy, something is not quite right? I don't know for sure, but I think not. Is it not necessary for a colony, after such a length of time, to make a stir and take a lunch, and, possibly, make other changes? Did you ever notice them rousing up periodically, and then quieting down again? Unless you are quite close to the colony you may not hear it, and it makes hardly a perceptible difference in the murmur of the cellar. So I would say you may find single colonies noisy, without any harm; but if all the cellar is noisy, something needs attention. Now, am I right in all this? Can any one tell us more about it? C. C. Miller.

Marengo, Ill., Mar. 6.

[This noise in a bee-cellar has always been somewhat of a mystery to me, and I believe your suggestions on the cause are good. There is one thing I feel pretty sure of—that is, if the cellar is above 50 degrees in temperature, and the bees are noisy, by lowering the temperature down to 40 they will become quiet. The only means of lowering the temperature with me has been to open the windows at night. That did two things—let in pure air, and the lower temperature created a circulation. Another thing I have noticed: If the temperature goes down too low, bees are apt to be noisy again. By closing the windows next morning, they would be quiet. As you say, the noise in one case is caused by a lack of ventilation, and in the other the cause was a lack of warmth. Perhaps some one else will argue that the temperature was not right. I have not been troubled much with extreme temperature in my cellar, but I have allowed it to become low in order to see what the effects would be. I have noticed one other thing: That one or two hybrid colonies that we had in the cellar would be making a roar when all the rest of the bees were quiet. I accounted for this on the ground that they were so exceedingly sensitive to a slight disturbance that they immediately entered their protest. These same bees, if outdoors, would have done it in a rather more forcible way.]
E. R. R.

OBJECTIONS TO FIXED DISTANCES.

C. A. HATCH RECOUNTS THEM.

While we are hearing so much about the advantages of closed-end frames and fixed distances, would it not be well to look at some of the disadvantages of them, and the advantages of hanging, or, rather, swinging frames?

Is rapidity of handling the only thing to be considered? and is it really so that the closed-end, or any frame having a device for keeping them a certain distance from each other, can be handled faster than common L. frames? It is said that one can take three frames at one time, and therefore can get along, presumably, three times as fast. Can not three frames of any kind (if one wants to lift so much at once) be taken at one time by putting your fingers between the frames to keep them apart. I have done it many times; but two heavy frames at once are about all the average bee-man will care to lift, and follow it up for any length of time.

If frames having end-pieces wide enough to fill completely the space, like the Quinby and new Heddon hive, I have found it necessary to loosen the frame at both ends, and sometimes they are so glued with propolis that they are fixed indeed; and in the Heddon hive I have had to spoil the first frame in order to get at the rest. Perhaps this may be owing to the frames filling the hive endwise; but suppose a space is left there, what a fine place for moth to hide, or for more propolis to be stowed! When bees bring in propolis and fill every crack and cranny with chunks as large as hazelnuts, and sometimes larger, we have to beware of the chances for storage left around the hive. "But," says one, "we are going to have the frames wedged so closely that no crack for propolis is left between." Can any form of wedge and follower bring them closer than a screw which was used in my case? and what is to prevent that wedge from being stuck solid with propolis? and can you get frames made so square and true that they will *all* come up chock against each neighbor? If you can, you have found a better workman than we have, and we have had some good work done. What is the matter with the round-headed nails recommended by Dr. Miller?

You must always put the frame in the hive the same way it came out, which makes an extra item to watch, and sometimes it is a real advantage to change ends with a frame. The nails are also always catching on the hive or on other frames, and bothering, especially if one wants to handle them rapidly, and that is just the point we are after. We had several hundred frames fixed this way some years ago, but used them only one year, when we removed every one, at no little expense and labor. The nails are also much in the way about using the uncapping-knife. This last point would condemn them for all extracted-honey men.

The Hoffman frame, which has closed ends only part way down, as I understand it, is perhaps open to less objections; but there are the same ones in regard to being stuck with propolis. What a fine place the V point between two frames is for it! Still, if the frames are wedged close, and fit snug, the part in contact is so short that not much effort will be needed to separate them. It also has the end projection to lift and handle it by, which with me is quite important. If we are to have frames fixing the distances automatically, let us try to get a good one, adopting the Jacksonian motto, "Be sure you are right, then go ahead."

Remember what a boom was made only two or three years ago on reversing frames, and then see how many are in use to-day. Are we not too much like a flock of sheep—when one leader goes, all make a rush, regardless of what we require. C. A. HATCH.

Ithaca, Wis., Mar. 26.

[I am glad of your article, friend H.; and believe me when I say I am just as much pleased to have the other side discussed as to have the one toward which I am leaning; the more so, because I know you are a successful bee-keeper, and candid and fair in your judgments.

I do not know that it is so in every one's hands, that the closed-end or Hoffman frame can be handled faster than loose frames. I know I saw Hoffman and Elwood handle their respective fixed frames faster than the average man will the loose frame. But as Mr. Hoffman in the next issue will touch upon this point and Mr. Elwood in the present issue, I will let them speak for themselves.

Hanging frames with nails for spacers, and such like contrivances, would be an intolerable nuisance, and I do not wonder that you discarded them.

To handle the closed-end or Hoffman rapidly, they should be picked up in pairs, and sometimes in trios. If they are full of honey, two will be enough to lift. If empty or nearly so, in the spring, then you can handle as many as you can span with your fingers. I know you can handle loose frames after a fashion in pairs, but not with the same facility that the Hoffman frames can be thus handled. I have tried both ways.

Those of us who have defended fixed distances did not intend to convey the impression that fixed frames could be handled in speed in proportion to the number of frames handled at once, as you seem to take it. We meant that the handling in pairs and in trios *assisted*.

For rapid manipulation there is another very important consideration. For closed-end or Hoffman frames a hive with a movable side, or, better, one with a loose follower, should be used and then you get lateral movement in its perfection.

Your experience with the Heddon closed-end frame is different from ours, so that we shall have to account for that on the score of locality.

What you say regarding closed-end frames in close-fitting cases may be a serious objection in many localities; and if so, we should be warned of it in advance; but this does not apply at all to the Hoffman frames or closed-end frames, used as Quinby advised.

And now about the propolis between the cracks. We have had no very great trouble on that score. So far, compression has obviated the trouble. But perhaps I should remark right here, that the Italians do not deposit propolis like hybrids or blacks. But in spite of all you say, everywhere in New York I saw every thing smeared with propolis; and if there is any place in the United States where propolis is deposited freely, it is in York State; Elwood says he never saw any more propolis than in his locality, and yet neither he nor Hoffman experiences any trouble from it with their frames. You say, with fixed distances you must always put the frame in the hive in the same way it came out. On this point I just won't agree. This may be true, however, if you take old hanging frames and make them into fixed distances with nails. But take frames that have always been fixed (that is, those that have never been subjected to the hit-and-miss spacing), and have always been handled properly, I am pretty sure there will be no trouble. Notice what Mr. Hoffman says in the following article. Mr. Elwood has told me the same thing.

There was a boom made in reversing, and it rather died out; but I am pretty sure that it is going to come up when the proper appliances permit of its more easy operation. Reversing with ordinary loose frames is impracticable; but with fixed frames inversion is not only more feasible but practicable; and, as friend Dayton said in the last issue, and as Mr. Chalon Fowls and others have insisted, I believe that more brood can be secured in a certain number of frames by reversing than by not reversing. If this is true—and our experience in the apiary inclines me to this opinion—then here is a point that we can not very well overlook. Fixed distances are going to make reversing possible where before it was impracticable (because the whole hive can easily be turned upside down and the combs won't topple over either), and there is nothing that makes such beautiful combs as reversing. I am very glad to refer you to an article from Mr. Hoffman, which appears next; and I would also advise you to read another from the pen of Mr. Elwood.] E. R. R.

THE HOFFMAN FRAME DEFENDED.

HINTS ON ITS MANIPULATION BY THE INVENTOR HIMSELF—MR. JULIUS HOFFMAN.

In GLEANINGS of Mar. 15th, Mr. W. W. Somerford is condemning closed-end frames in quite a severe and positive way. I have but very little time to write, and perhaps still less inclination and ability to do so; but Mr. Somerford's sweeping assertion, and the apparent tendency in his article to warn beginners against the Hoffman frame, induces me to make a few remarks in your valuable paper—unless GLEANINGS has closed its pages to any further testimony on the Hoffman side, as that gentleman calls it.

I will begin by saying that I never made the slightest attempt, in word or writing, to persuade or induce anybody to adopt or use my style of frame until quite recently. When the now so-called Hoffman frame was brought to notice in GLEANINGS I thought it best to state how I make and use the suspended, partly closed-end frame, and tried to explain what I thought their advantages.

What induced the editors of GLEANINGS to bring this frame before the public, I do not know; but I was much surprised, like Mr. Somerford, that my style of frame had worked its way into so many apiaries, even to most of the distant States.

I can assure Mr. Somerford, too, that I know of a good many beginners who started with the Hoffman frame, and are quite successful with it. I also know of many good practical honey-raisers who have worked with the common loose or swinging frame, and use the Hoffman now exclusively. If Mr. Somerford has used the Hoffman frame as made by me, and described in Gleanings, will he please tell the readers of Gleanings in how many colonies and for how many years he has used them?

If he is of his friend Woodward's type, who has sometimes to leave the close-fitting frames apart a little, on account of irregular combs, and can not interchange them very well because his combs differ so, and as he can not keep his hives level, the combs are out of true. If he is that kind of bee-keeper it will, I think, be better for him not to handle a spaced or close-fitting frame; or, better yet, work the old box hive. We have, in the working season, from eight to ten thousand frames to handle and in use, and any of them will fit in any colony between any two combs. Is Mr. Somerford not aware of the fact that some of our most practical and extensive honey-raisers have used a close-fitting frame for a great many years? Please ask them whether the frame they use is abominable and unbearable to them.

I have no doubt that these successful men can handle their close-fitting frames quite as fast and conveniently as Mr. Somerford his swinging or loose frame. Has Mr. Somerford ever moved several hundred colonies to different localities and back again every season? If so, will he please tell us how he would fix his swinging frames to load and unload to take his bees to different localities over rough and hilly roads, or take his filled combs home for extracting from the different apiaries as we have to do?

My hired man (I often have a green or inexperienced man to do it) can, and has often done all the moving of the bees to five and six different yards in spring and fall, without any assistance.

If I used a loose swinging frame it would require such an amount of time, labor, and care, to move the bees every year, that I should not want to do it at all. It would be "abominable and unbearable" business, and I would give it up.

DOES THE HOFFMAN FRAME KILL BEES? PROPOLIS; DOES IT HINDER OR ASSIST MANIPULATION?

In regard to bee-glue, I will say that we have no trouble from it with our frames and in our climate, when the frames fit as well as they ought to, and are always pushed together well. I, indeed, prefer the gluing together of the frames by the bees to a loose shifting frame, as I can lift and carry the hives more handily. I hardly believe that Mr. Somerford gave the Hoffman frame a fair trial; for if he had, he would not say it kills bees.

In examining or working a colony of bees, the frames ought not to be pressed quite close together until the work with that hive is done, when all the frames of the hive should be pressed together firmly in a lot. If a little smoke is used before, to drive the bees down where the frames are not close fitting, no bees will be killed. Any person at all fitted for the bee-business will soon handle such frames without killing bees.

In conclusion I wish to say, that, if a bee-keeper can not become expert enough to handle a close-fitting frame well, he should not discourage others from trying them, because I am certain there are many in our great country who are progressive and clever enough to make a success in honey-raising by using improved appliances or fixtures. Julius Hoffman.

Canajoharie, N. Y., Mar. 23.

[I will say to our readers that Mr. Hoffman is modest and retiring in disposition, and one who is but little inclined to push the merits of any of his devices. He has no interest in bee-supplies, and, in fact, never had, that I know of. What he says above, I am sure was influenced only by his free-hearted disposition to do the bee-keeping world good. He has used extensively the loose hanging frame, and I think he can prove every statement made, just as he did to me when I visited his place some six months ago. His success with 600 colonies, and his big crops of honey, secured largely by his own individual labor, means something.

The reason why we thought best to introduce his frame was because, here and there all over the country (when we were agitating fixed distances) bee-keepers were asking us to look into its merits. So many of these came in, and they argued with so much show of reason, that this was largely influential in inducing me to make a visit east, to see Mr. Hoffman handle his frames; and the result was, that I was so thoroughly convinced of their merits I knew we should be doing bee-keepers a good turn by offering them to the public.

J. H. Nellis advertised Hoffman frames something like ten years ago; and after his journal ceased publication in 1882, comparatively nothing more was said in regard to them; but it seems they have during these years been silently working their way throughout the country among bee-keepers, solely on their merits. Supply-dealers may boom a poor article, and get it generally introduced; but when an article, without any booming for ten years, works its own way into favor, it must have intrinsic value, or it would die out.

I believe the Hoffman frame is better adapted to beginners than any other frame I know of. They can not help getting their combs spaced right; and I know by experience that beginners seldom if ever space loose frames properly, and then they write to know why bees bulge their combs so badly, or why their combs are so crooked, etc.

In the next issue Mr. Hoffman will show how to handle the Hoffman frame, by an illustrated article.] E. R. R.

THE HETHERINGTON QUINBY HIVE.

MR. ELWOOD TELLS HOW TO HANDLE IT, AND EXPLAINS ONE OF THE SECRETS OF ITS RAPID MANIPULATION.

The junior editor of Gleanings has canvassed the subject so exhaustively as to leave little to be said on fixed distances with closed-end frames. I was glad of an opportunity of showing the workings of our hive to a practical bee-keeper familiar with the swinging-frame hive in its various modifications; for I had surmised, as Mr. Root admits, that my statements as to rapid and safe work were, by many, disbelieved. However, I am pleased to know that my advocacy for these many years of fixed distances and closed-end frames, while counted a serious blunder, was attributed to nothing worse than ignorance.

THE TWO REQUIREMENTS OF A GOOD BEE-HIVE.

A good bee-hive must fill two requirements reasonably well to be worthy of that name. 1. It must be a good home for the bees; 2. It must in addition be so constructed as to be convenient to perform the various operations required by modern bee-keeping. The first of these requirements is filled very well by a good box or straw hive. Bees will store as much honey in these hives as in any, and in the North they will winter and spring as well in a straw hive as in any other. They do not, however, fill the second requirement; and to meet this the movable-frame hive was invented.

WHY QUINBY INVENTED THE CLOSED-END FRAME.

Mr. Quinby observed, soon after the introduction of the Langstroth hive, that bees did not winter as well in them as in box hives, on account of the open frame; and he remedied it by making his frames closed end. Dzierzon also discovered that the open frame infringed upon the welfare of the bees, and says: "These passages are unnatural, and they carry off the necessary heat and moisture from the brood-nest and winter quarters of the bees, so that colonies generally winter badly." Abbott, late editor of the *British Bee Journal*, says: "There is nothing more unnatural in hive arrangement than the absurd practice of making or leaving spaces round the frame ends." Bees usually close up the space between the combs and frame ends or side walls of hives, as far down as honey extends, and undoubtedly our frames should be closed as far down as the instinct of the bees teaches them to close this space, which is often to the very bottom of the frame. This close space saves much heat, and enables weak colonies to build up in the spring that in an open-end frame would have no chance whatever.

Our division-boards, or panels, as we call them, are close fitting at top, bottom, and ends. They are always at hand, thus making it very convenient to contract the brood-nest to suit the requirements of the smallest colony, or to enlarge it to suit the largest colony. With a quilt over the top of the frames, every space between the combs is made so close that it is easily kept warm, and really gives our hive nearly all the advantages of the box hive, with the additional one of combs removable at pleasure.

MOVING BEES ON CLOSED-END FRAMES.

Our hive is portable. No cumbersome rack is needed in moving bees, for two hives sit side by side in the bottom of the wagon, and one hive piles on top of another, without need of sticks between. In preparing a colony for moving, we shove out the entrance slide in the bottom of the hive, and put in its place a wire-cloth slide to give the necessary ventilation. Then two screws are put in—one through each side of the bottom-board into the edge of the hive. An average man will consume about a hundred minutes from the time he reaches a yard until he drives out with a load of thirty-three swarms. The two screws mentioned fasten the bottom on so securely that we have had no accidents on the road serious enough to warrant unhitching the team from the wagon. Our bees are usually drawn over rough, stony, and hilly roads, but we have no queens or bees killed from frames flopping together, nor do we have any combs broken. It is a long time since I saw a comb that had been broken on the road.* When our bees were housed in November, two men in the cellar and three outside with a team put them in at the rate of two colonies per minute. With the swinging frame they could hardly have handled them so rapidly, saying nothing about their safety.

Not only is our hive movable, but our frames are also movable. In walking up to a hive, one motion lifts the hive proper from its bottom-board, and places it at the side of the exposed frames, where it forms a seat of convenient height. The iron roof is nailed to the hive, and, of course, always goes with it. Only in the hottest weather is there a shade-board to be removed. Another motion with one hand removes the quilt covering the frames, and the other hand blows a puff or two of smoke from Jumbo, while the first removes the cord holding the frames more tightly together. You are then ready for business. If you are looking for the quantity of brood in the hive, you can remove the frames in pairs; for they are easily and rapidly handled in this way, and one side of a comb is usually a duplicate of the other side. The bottom-board is large enough so that the frames removed can be hooked on the bottom near you, and far enough away from the others to have ample room to get a good look at the next comb (see Fig. 1).* This is a valuable feature of the hive, as you can have always a good place for combs without setting them upon the ground where you are in danger of losing queens and damaging brood, besides other annoyances. The hive-bottom as we use it for comb honey is 18 inches across, while the maximum number of frames used for this purpose would occupy only 11½ inches. In removing frames, a small knife† will readily loosen one end, when they can be unhooked from the bottom. Quite often a knife is not necessary, but it is advisable to carry one.

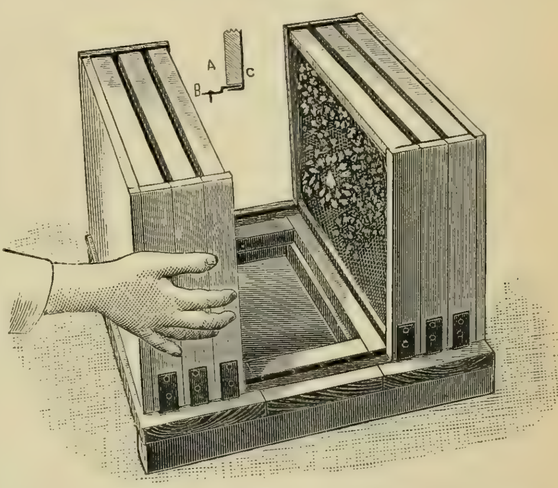


FIG. 1. QUINBY CLOSED-END FRAMES MANIPULATED.

On looking over combs it is best to set them together on the bottom, see Fig. 1, so that bees can neither get in nor out between the ends of the frames. This is best for various reasons.

---

*Mr. Root has told you something about our roads, which were at their best when he was here. Perhaps they were not very smooth then, as, on coming down one steep hill, I caught him holding fast to the seat with both hands. This was not when our bees were objecting to having their pictures taken, for his hands were busy then, and I remember that *I* was *on foot*.

*Mr. Elwood several times showed me the queen by simply dividing the hive in *perpendicular* halves, as shown in the engraving. Often this was all that was necessary, and the hive was closed up. Many times he handled and examined into hives without removing a single frame. This is why he often can find a queen quicker than he could in a loose-frame hive in a box.—E. R. R.

†A good penknife will open any hive, and for nearly fifteen years I carried and used exclusively the same light jack-knife, breaking it only in taking off clamps of honey.

In cool weather it saves heat, also annoyance from robbers; and when looking for queens the bees do not bunch up when the combs are the proper distance apart. Also when we have all the combs looked over, they are ready to have the cord and quilt put on them after a shove (with both hands as per Fig. 1) slides them all to the center of the bottom-board, ready for the hive. P. H. ELWOOD.

Starkville, N. Y., Mar. 15.

Continued next issue.

[In the next issue Mr. Elwood will explain why the closed-end frame as Mr. Quinby recommended it does not kill bees. This will also be illustrated with suitable engravings. Mr. Elwood has given very truthfully the two requirements of a bee-hive—one suited to the bees, and the other to the bee-keeper. We all agree on the first requirement, but we do not all agree as to what constitutes the second one. I will say that the engraving, Fig. 1, was taken from a photograph, and is very nearly accurate. The manner in which the frame is hooked to the strap iron is not entirely correct; but this will be illustrated in the next issue, and shown right.] E. R. R.

CLOSED-END FRAMES.

MRS. AXTELL DISCUSSES SOME OF THEIR DISADVANTAGES.

Mr. Axtell has given you his views about the standing closed-end Quinby frames and hive, which features of the hive I like too; but there are some things about it that even I do not like. In the first place, one must be very careful to push the frames up tight each time; and even if they are pushed up tight, the bees will stick on a little bee-glue along the crack that was made when pried apart. Then next time a little more will be put on, and the next time a little more, so that they will unavoidably get further and further apart—that is, spaced further apart unless the apiarist will at least once a year scrape between those combs.

My plan has been to get around once in two years myself, at least, and take down the front of the hive, and, with an old butcher-knife, I pry each comb apart and scrape between the two, then scrape off the front board of the hive, with a scraper and the front end of the brood-frames (I scrape the front end before being pried apart). Then I go to the back end of the hive and take down the board and scrape off the back end of the frames before prying them apart; then I pry them apart and scrape between the combs; then scrape off the board before putting it up.

I have always made it a point, about once in two years, to have the edges between the combs where they come together scraped, and the front board once in one year; and the back board, which is often taken down, scraped oftener. Now, if that scraping is neglected, in a few years an immense amount of wax and propolis would be put in, so that the combs would be spaced much too far apart; and the frames, by the addition of the propolis, would become so long we could not shut up the hive. For that reason, year before last I strained my arms drawing the corners close together so they could be clamped. We are about to fix all our hives ⅛ or $\frac{1}{16}$ of an inch longer than they were needed when new.

Always, in the fall, we have a large number of brood-frames not needed in the hives, and sometimes they are filled with honey, and often not filled; but I generally take pains to have them all cleaned of propolis between the edges where they come together, as it is very much easier cleaned out of the hive than in the hive, where the bees are constantly poking their heads out in my way, and I have to use the smoker to keep them back.

Now, another serious objection to the standing closed-end frames is especially serious in the hands of our helpers or beginners. At the front ends, if the bees run, they will generally run down at the front end, and get just where we want to set the frame. I can scarcely ever sit and look at one of my helpers replace the combs in the hive, because they will kill so many bees at that front end on the bottom, so there is danger of killing the queen also. Mr. Axtell does not, nor do I, kill many bees in that way; but we are careful not to get them to running, and I know better how to prevent getting them down there; but if they do get down too bad, then we loosen the front board a little until the combs are returned; but in that case the frame must be caught by the hoop-iron catch at the bottom, or they will have to be watched pretty carefully, or they will tumble over.

I have thought, if we were making all new frames why not have the lower end of the front bar a mere point? but then the bees would, a few of them, get between the end of the frame and the front board unless there was a bee-space between the frame and front board.

I think we like the hive and frame we have always used better than any other, because we better know how to handle it. But there are advantages in this style of hive, I am quite certain, which we can not get in the hive with a hanging frame not having closed ends.

Roseville, Ill. MRS. L. C. AXTELL.

[I do not know that I clearly understand just what kind of a closed-end arrangement you use. If I mistake not it is the original Quinby without the iron hooks. You know that Capt. Hetherington and P. H. Elwood use the Quinby system, slightly modified. As they use it, I do not think they are troubled much with the killing of bees in the way you speak of.

I know that propolis will build up between the uprights or closed ends; but, if I am correct, this can be largely obviated by compression. This is so with the Heddon shallow closed-end frames. Although we have used one of his hives some three or four years, there is scarcely more propolis between the uprights than there was the first three months it was used. The compression keeps it out. I shall be glad to have this subject discussed, particularly by Mr. Elwood and Mr. Hoffman, and by others who have had experience "along this line" as Doolittle says.] E. R. R.

WAX SECRETION.

PROF. COOK STILL THINKS WAX IS SECRETED ONLY WHEN NEEDED.

Friend Root, it is pleasant to read the replies in the last number of the *American Bee Journal*, to the query regarding wax secretion. Nearly all think bees do not secrete except when it is necessary in the economy of the hive.

In the March 15th number of GLEANINGS you remember I went a little further. I urged that bees secrete only when the wax is needed, as a rule, and gave, as the best hypothesis explaining this that quiet was the probable explanation. I should add, quiet under full nutrition. That is, the bee is functionally active, eats much, but exercises very little.

In your foot-note you remark that you formerly thought as I do; but you add, that abundant wax scales, produced while feeding sugar syrup—so abundant that they fall to the bottom of the hive—makes you skeptical. I have noticed the same thing that you speak of, and it the rather confirmed my view. If we feed syrup in quantities, the bees are nervously stimulated, and I think the functional activity is by no means slight; yet, how little they exercise! There is no occasion for much exercise. With a chance they will build comb very rapidly. Supply them a full set of combs, and they have no use for the scales, and the latter lie thick on the bottom-board. This strengthens me in the view that wax is secreted only under those conditions which usually prevail when wax is needed. That is, the bees are functionally active under high nervous tension, and yet are not exercising much, either from choice or because, as in case of feeding, there is little or no occasion for much exercise. The fact that they do not secrete wax except when it is needed, I feel certain is, as a rule, well grounded. If any one can give a better solution of this problem than is afforded in the theory of physical quiet in conjunction with a stimulated condition, I should like to hear it. A. J. Cook.

Agricultural College, Mich.

E. FRANCE GIVES US SOME SHARP FACTS THAT WE CAN NOT WELL GET AROUND.

In March 15th Gleanings, page 212, Prof. Cook gives us an excellent article on wax secretion, and A. I. Root makes some good remarks. Now, I don't intend to criticise either of you; in fact, I agree with both of you. But I have a theory of my own as to when and why bees secrete wax. They secrete wax whenever they have more honey than they have combs in which to store it away. At such times they have to hold their honey in their sacs—they have no other place to put it. The wax is secreted as a consequence of holding the honey in their sacs. Now, this is the whole sum and substance of wax secretion. Give a new swarm of bees a full set of empty combs, and will they secrete wax? No, not much; but give them an empty hive when honey is plentiful, but no combs, then the secretion goes on rapidly. Why? Because the bees' sacs are full of honey, and they have to hold it until combs are built to store it away.

Another case: Hive a swarm in an empty hive when there is a dearth of honey. When the bees have to eat all the honey they can get to keep alive, will they secrete wax? Not any. They have no honey in their sacs. I hived a swarm last September—a good-sized one—and they lived until cold weather, but never built an inch of comb—then starved. Why did they not secrete wax? No honey.

I have seen it stated in the bee-papers that only young bees secrete wax. Now, I think that is a mistake. I have no doubt that young bees do secrete wax; but that they never secrete wax after they are old enough to go to the fields and gather honey is not so. I know that bees will secrete wax and build combs until they are six weeks old. Can I prove it? Yes. Several years ago a bee-man near here hived a swarm of bees in a frame hive that I sold him. Just 21 days after, they had filled the hive full of combs, and a set of boxes with honey, and swarmed. That day the swarm was put into another hive, and they filled that hive also, in three weeks. Now, don't you see that this last swarm of bees were at least a part of the first swarm? or in other words, every bee in the last swarm was one of the first swarm, and was not less than 21 days old, and they could not get young bees in the second hive in less than 21 days more? So the same lot of bees were secreting wax and building comb for six weeks. I believe that, as long as a bee lives, it can secrete wax and build comb with it, and that old bees can secrete wax as freely as young ones, and that wax is never secreted to any amount unless the bees have to hold their honey for the lack of room to store it away, and they can not secrete wax unless they are holding honey in their sacs. E. France.

Platteville, Wis.

[Friend France, I congratulate you on the point you make in regard to bees secreting wax when they are six weeks old. I never thought of it before, but your argument is unanswerable. A swarm that casts another swarm inside of 21 days must surely send out only old bees. I have been satisfied for years that old bees can secrete wax, nurse brood, or do almost any thing else, on a pinch.] A. I. R.

DOOLITTLE TELLS US WHAT HE THINKS OF MILLIONAIRES, AS WELL AS WAX.

I read with interest Prof. Cook's article on page 212 of Gleanings for March 15, and heartily wish he were correct. He may be so during a time of moderate flow of honey, with no desire on the part of the bees to swarm; but with a good honey-flow, and a disposition on the part of the bees to swarm, I can only think him in error, in the light of past experience. Take his example of the "cow secreting milk when there is a young calf that must have milk;" and instead of proving what he wishes it to, it most surely proves that wax must be wasted when a swarm of bees is hived in a hive fully provided with comb, when we come to apply that example to the bees. The cow secretes milk according to "nature's arranging" before the birth of the calf, so that it may have a supply when it enters into the world; so the bees begin to prepare for their future home some length of time before they leave the parent colony by secreting wax, so that they may be prepared with the needed material when they enter their new hive, which, as a rule, is all "swept and garnished," only as man's hand changes their usual surroundings. If the professor has ever examined a swarm of bees as they hang on a limb, waiting for the scouts to return and report "a future home," and failed to find wax secreted in the wax-pockets, he has found a state of affairs that I never did. With this wax already secreted, what is to become of it when the swarm is hived in a hive already fully furnished, unless it is wasted? That it is not found on the bottom of the hive is no proof that there was no secretion, or that it has not been wasted; for I have repeatedly seen bees leaving the hive with wax scales in their mouth, and once or twice have seen them drop them soon after taking wing, although I believe that the greater part of this waste comes about by an unnecessary thickening of the combs, and a useless daubing of wax about the hive. I have seen the limbs of trees, on which swarms have clustered, plastered over with wax, the secretion was so great; and when swarms have been hived on full sheets of foundation, I have scraped the cells off the foundation, which most would call "foundation drawn out," only to find the foundation in as perfect condition as it was when it was placed in the hive, the bees simply adding their wax to the side walls of the foundation. I may be wrong, but I can see in this only a waste of wax, or a waste of the foundation; have it which way you please. In times of a slow yield of honey, and perhaps I might say at all times, I do not think as much wax would be secreted when the swarm was hived on empty combs as there would be in an empty hive, for the continuous secretion which goes on after the swarm is hived in an empty hive till the hive is filled with comb would be avoided, and thus a part of the secretion would be stopped. It is for this reason that I have advised using only starters in the sections if the hive is filled with combs below, or using only starters in the frames below, if the sections are filled with combs or with foundation. In this way the wax which the bees have already secreted, and that which is in the process of secretion, is saved, hence no waste at any point.

THOSE MILLIONAIRES.

I was taken by surprise at what I found on pages 213 and 214 of the same number of GLEANINGS; and, friend Root, as you took a column and a half to reply to friend Heselton's half-column, and then called a halt, perhaps you will allow me to say a few words for both of you in the column still due Bro. H. With you, I agree that a man is not necessarily wicked because he is in possession of *much* money, nor is he in a wicked calling because he is a lawyer; but if his money comes to him through fraud or dishonest practices, in which his poor neighbors are robbed of the amount he gains, above what he earns, then he can only be classed with sinners, no matter how many charitable institutions he helps or founds; and if he is a lawyer, and lends his influence toward the framing of unjust laws, laws which oppress the widow and the fatherless, then the cries of these "laborers will enter into the ears of the Lord of Sabaoth," and happy will you and I be, friend Root, if we are found in opposition to such practices, and if we lift up our voices and our ballots against a state of things which allows of this oppression; for then we are not partakers in these crimes, even if they do not cease to exist. There are only three ways in which money can be secured: By earning, by charity, and by fraud (theft). When "old Hutch." secured his millions by the wheat corner a few years ago, did he earn a cent of it? No, he stole it; and by his becoming that much richer, those who earned the money which accumulated in his hands were just so much poorer. If he had given all this pile to good institutions, the Lord would not have blessed him for the gift, although he might have blessed the institution. So of railroad wrecking, trusts in oil, sugar, coal, etc., which rob the laborer of his hire, which things are allowed to exist in our land by the votes of the people, votes which they cast ignorantly, by allowing their minds to be drawn aside from the right and real issues of the day by scheming politicians. Then, by our present tariff laws the poor laborer of our country is compelled to give charities to the rich, just in proportion to what he is obliged to consume; and so we see thousands and millions of our people suffering for the actual necessities of life that a few thousands of our people may become rich. John D. Rockefeller is reported to be an eminent Christian gentleman, and yet thousands of the poor seamstresses of our land are spoiling their eyes, and have been for the past years, because they could not earn the wherewith to buy oil enough to have sufficient light to sew during the hours of the night which they were obliged to work to keep soul and body together. Now, Bro. Root, something is wrong somewhere, and it becomes you and me to see that we are on the right side, and that is why I write on this theme. I know a bee-paper is not the proper place for a discussion of politics or religious doctrines; but as you took a column extra on that subject, I thought you would allow the same space to me, if I were not abusive, and I have tried not to be. G. M. DOOLITTLE.

Borodino, N. Y., March 28.

[Friend Doolittle, Prof. Cook will have to answer you in regard to the wax problem; and if I really took a column and a half before, I certainly ought not to occupy any space just now. But we should all be careful to look on both sides of these great national questions, and we should also beware of uncharitable extremes. There is a safe ground, and a right one in all these questions, and we who are striving to follow Christ Jesus ought not to be very far from each other in our opinions.]

THE VALUE OF EMPTY COMBS; A VALUABLE EXPERIMENT, SHOWING THAT BEES SECRETE WAX WHEN COMPELLED TO BUILD COMB.

With Prof. Cook, I greatly doubt whether bees have to secrete wax unless there is a great honey-flow, and no place provided for them to deposit it. A few years ago this same subject was talked up in the bee-journals; and as I had helped some in an apiary for over 20 years, and had read so many different opinions and theories on the secretion of beeswax, I felt very much like making a few observations, and it was not long before an opportunity presented itself. It was a very warm morning in the swarming season. Mr. M. was called from home, and I was left alone to care for the bees. In a short time the swarming-note was sounded, and "the bees had swarmed." We were making use of some drawn-out combs at the time, and I got a hive, filled it with some of them, and hived the bees; then I wiped the sweat from my face, and returned to my labor. This was swarm No. 1.

I had hardly got settled down to work, when "buzz, buzz," and out came another swarm of bees. "Ha, ha!" I said to myself, "now is my time to experiment a little." So I went and got a hive, filled it with empty frames, and hived swarm No. 2, and then awaited results.

The next day I went to look at them. Swarm No. 1 I found very busy at work bringing honey from the field, and depositing it in the combs; and on the alighting-board and bottom of the hive there was quite a quantity of those little wax scales; but it was very difficult to find any scales in the wax-pockets on the bees. Then I went to No. 2 and found there were not more than half as many bees going and coming from the field as there were from No. 1. I very gently raised the cover and looked in, and found the rest of them hanging in festoons to the top-bars, quietly working at their trade of comb-building, while those that came from the field seemed to be bringing honey for them to consume, to produce the wax to build the comb from; and the secretion of wax was very plentiful on the bees, but there was none on the bottom-board nor around the entrance to the hive.

They worked on in this way for a few days, and built comb very fast; then the yield of honey in the field diminished, so they could get but a little; and although they were still inactive, the wax secretion diminished, and comb-building progressed very slowly. Therefore I think consumption causes production; and if circumstances are such that the bees consume a large amount of honey, they they will secrete a large amount of wax. But this is no saving; for, if the honey that they consume to fill the hive or boxes were stored in surplus boxes or comb, it would pay for combs or foundation to fill a number of hives. OBSERVER.

[My good friend, you have given us a most valuable experience. First, it indicates beyond question that a colony will store more honey for the extractor when they have a full set of combs. Sheets of foundation would probably come next to full combs; but empty frames are away behind. Our older readers may remember that I made experiments in just this line nearly twenty years ago. A new swarm, with a full set of empty combs, does, however, secrete quite a little wax. They put it on top of the top-bars, extend out the length of the cells wherever the space will admit of it, and often put little fins around the end-bars. The point of great value to bee-keepers is this: A new swarm, hived on empty frames, will at once—at least the greater part of them—hang idly until the wax scales are secreted; whereas, with full sets of combs, nearly all these bees could go at once to the fields for stores.]

WEST'S CELL-PROTECTOR.

A NEW AND VALUABLE DEVICE.

The cell-protector was worth over $100 to me two years ago in swarming-time, as I requeened over 100 swarms with cells from my choicest stocks, and at the same time stopped swarming where the cells were introduced. My bees wintered well and came out strong the following spring, while others lost very heavily all around me.

I dare not say that it is a positive fact that the method I practiced two years ago will always prevent swarming, but it did with me in four different yards, and it was a swarming year too. The hives that I did not treat that way nearly all swarmed, and in many of them we killed the queen while the swarm was on the wing, and destroyed the cells in the hive and gave them a choice queen-cell in the protector, from a hive that had cast a swarm five or six days before. This is easily done while the bees are on the wing.

This way of requeening a yard of bees costs nothing, and gives you a chance of doing it when swarming-cells are plentiful, and this is the time to do it, because we can get better queens; and by going to a hive that has not swarmed, and especially if for any cause the queen is condemned, kill her and destroy the cells if any are started, and give them a choice cell in the protector at once.

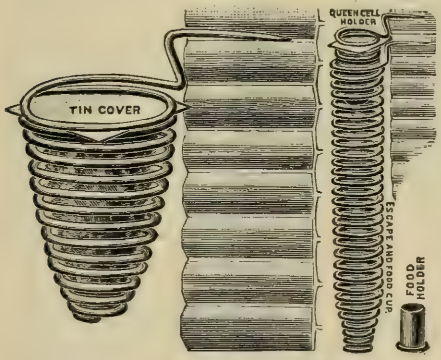

Fig. 1. *Fig. 2.*

N. D. WEST'S SPIRAL-SPRING CELL-PROTECTOR.

If you want to raise any virgin queens, go to a hive that has cast a swarm five or six days previously, cut out carefully all the cells you wish to save; place them in the protectors; lay them in a box of cotton, or have a block with a number of holes to set them in until you are ready to use them. Now, when all cells are cut out, just place the cell, as it is already in the protector, on the side of a comb in the same hive. By pushing the spur of the protector (see Fig. 1) into the comb it will stay there; and with the long queen-cage placed below (see Fig. 2), it, with its spur pushed into the comb, will also stay, and there is queen food in the bottom of this cage, so that, when the queen hatches, she will run down into this cage. In this way you can have a queen-nursery in any hive, and hatch out as many queens as you wish. Now, after the cells are hatched you can make as many nuclei as you have queens, by just taking one frame with adhering bees, and place in an empty hive; place another comb by the side of this; give them one of these virgin queens; close the hive, and so on until the cells are used up, and wait until they lay; then do with them what you please.

HOW TO USE THE CELL-PROTECTOR.

Hold the small end of the protector between the thumb and first and second fingers of the left hand. Hold the queen-cell by the big end in the right hand in the same way. Now you are ready to put the cell in; and as soon as the fingers of the right hand touch the cage, it will shorten up by pushing slightly, so as to fix the point of the cell just through the small end of the protector. Let loose with the right hand, and the coil will spring back and cover the butt end of the cell; then slip the tin cover in between the wire coil, just above the butt end of the cell; then you are ready to put the cell in a hive. Then just spread the combs apart far enough to put your hand in; now push the spur of the protector in the comb where you want it (see Fig. 1). I leave them just below the top-bar. Now place your frames, and you are done. The top of the protector is in plain sight when the hive is open. Care should be used to handle the cells right side up, without a jar. It is a satisfaction to look in a few days and find your cells all whole except where the queen has helped herself out. The bees can not destroy the cell before she hatches, if properly put in; neither will it be destroyed by spreading the frames if you wish to do so. N. D. WEST.

Middleburg, N. Y., Feb. 3.

[Mr. N. D. West is one of those bee-keepers at whose place I stopped in my bicycling tour. He owns some 400 colonies distributed in three yards. Although I made at his place a very brief call of only some fifteen or twenty minutes, I became convinced of the fact, by looking around with his son (the father was absent), that he is one of the bee-keepers who ought to let their light shine a little more. I met him for the first time at the Albany convention, and there he showed me a spiral-spring cell-protector. Several bee-keepers who have tried them said that they were a good thing. I have since been informed that Capt. Hetherington considers them so good that he has ordered 500, and that P. H. Elwood also wants a lot of them, and that both say they are ahead of any thing else they ever saw for a protector. Mr. W. L. Tennant said he would rather do without comb foundation than to do without these protectors. This estimate is perhaps a little strong.

I am well aware that this looks like free advertising; but when so many good bee-keepers assure me it is a good thing, I am glad to give it this notice, particularly as Mr. West charges a very reasonable price for them. As he pays for advertising space elsewhere, he can not be accused of taking advantage of this notice free. We are well aware that the principle of the protectors is old, and that Doolittle has used a *wire-cloth* cone for years, but I believe the idea of using a spiral spring is new. The point of superiority over wire-cloth cone-protectors is, that the spirals adjust themselves to the size of the cell, causing the tin slide shown in the engraving to press down on the top of the cell, so that the end, or point, of the cell is squeezed against the apex of the cone. With the wire-cloth protectors I have known bees to push the cell up, crawl inside of the cone, and gnaw into the side of the cell; but they could not very well do it with Mr. West's spirals.

The point he makes, that the requeening can be done during swarming-time, is a good one, as is also the point that an extra-long cone can be attached to shorter ones, the queen hatched out, and be retained a day or two until a place is found for her. The facility with which these cones can be attached to the combs is another point in their favor.] E. R. R.

EVAPORATING HONEY BY SOLAR HEAT IN FLORIDA.

W. S. HART'S DEVICE, AND HOW HE DOES IT ON A LARGE SCALE; HE THINKS SOLAR EVAPORATED HONEY IS NOT INFERIOR TO THAT RIPENED BY THE BEES.

By request of some of your southern correspondents, backed by your own, I give you a description of my method of curing extracted honey. But first let me say I had a short interview with the editor of *The Florida Farmer and Fruit Grower*. The editor, in commenting on my honey, said, "Not content with the desiccation done by the bees, he reduces it in a sun evaporator, in a large pan under glass, to a consistency so dense that it will keep a long time without candying." The honey shown to editor Powers was cured more than that which I usually send to market. I cured it while testing the evaporator to see what it would do, and to see whether thorough curing with solar heat would darken the color. His description of the honey was a correct one, and shows that there is no reason for uneasiness on that point.

My honey-house is set upon a concrete base, about two feet high, bringing the floor of the lower room below the surface of the ground, and the sills a few inches above ground. Here in this lower room I store extracted honey in barrels. From this room there is a large air-pipe running out at the top of the building, which keeps up a circulation of air.

Work for the apiary, such as extracting, is done on the next floor above, while the third floor is used for storing empty hives.

From my large geared Stanley extractor the honey runs into a tank capable of holding 1350 lbs., that rests on the floor in the northeast corner of the extracting-room. The honey passes from this to the evaporating-pan by way of a faucet and a tin pipe projecting through the side of the building. The evaporator is made of heavy tin, and is incased in wood, as are the tanks also. It is 8 feet long, 4 wide, and with sides 2½ inches high. Every four inches of its length there is a tin partition 2 inches high, running from one side to within 4 inches of the opposite side, and alternate ones soldered to the opposite sides, so that the honey flows back and forth across the pan, a distance of about a hundred feet, before reaching the faucet at the lower end, through which it falls into a tank below, of the same capacity as the first mentioned. Any one who has seen a syrup evaporator will fully understand the workings of this one.

The tank below runs on trucks and a track, and, when filled, it is rolled out to the large sliding-door that divides the evaporating-room from lower story of the main building. From the faucet in the tank, the honey runs directly into the barrels, which are placed on end on the floor of the storing-room.

I fill all my barrels at the end, for several good reasons. When full the barrels are bunged up tight, and are ready for market, except that I always drive up the hoops just before shipping, and put double-pointed tacks behind them to prevent the possibility of slipping.

The evaporating-room is built on to, and runs out 11 feet from, the north side of the honey-house, and flush with the east side. The east wall is 5 ft. 6 in. high above the floor; the back wall 6 ft. 9 in., and the room is 5 ft. 4 in. wide. Three sash, 3x6 ft., are used to cover the room, except next to the main building, where the shadow falls. The evaporator is arranged to go close up to the glass, and can be lowered or raised at the north end to increase or diminish the speed of the honey-flow according to the heat and amount of curing desired. The evaporating-pan can be taken down and carried into the storing-room when not in use.

In both the front and back wall of the evaporating-room there are two rows of 3½-inch holes, bored and covered with wire netting, to allow a free circulation of air over the honey. The past season I have also left the door of the room open most of the time, as I find that, the greater the circulation of air, the quicker the honey cures.

The evaporating-pan is put quite close up to the east side of the room, leaving a space on the west side for a person to work over the pan to scour it or clean honey out of it when a light grade is following a dark one. The tank below is laid on casings that raise them a foot above the floor. This makes it more convenient to handle the tank or to draw honey from it into pails for home sales. The utility of the evaporator consists in the fact that honey can be taken from the hives when not over a third capped, and it can then be cured more thoroughly than could be done in the hives by the bees, thereby very largely increasing the crop. Capping honey is a slow and expensive process. By this system an even grade of honey is obtained, with much less labor and expense than when left longer in the hives. Some able men claim that honey is better flavored when ripened by the bees. I can not agree with them in this, nor do the returns and reports from those who sell my honey indicate the correctness of this theory. Nor could any bee-keeper, who has ever tried, tell me with any certainty which sample of honey handed him was ripened in the hive, and which by sun's heat. Usually they select the latter for the former, as it is usually of a heavier body. With the arrangement here described I have no trouble in thoroughly curing my crop of fifteen to twenty-five thousand pounds, and I could handle still more without enlarging my outfit, though a larger evaporating-pan would be an improvement. I have to-day 113 colonies, perhaps, of bees. W. S. HART.

Hawks Park, Fla., March 16.

[Many thanks for the full details of your arrangements, friend H. Although we have described similar ones before, we have not heretofore had such a report from direct practical use. My experience has been, that, for drying lumber, evaporating fruit or vegetables, or anything of this sort, a very large volume of dry air should be made to pass over or through the product. You did not tell us how long it took to evaporate a barrel of honey. Of course, it would depend upon how thick it is to start with. Very likely your locality would give you more and stronger sunshine than we get here, especially in March and April. This present spring, up to date of writing, April 4, has been cloudy and rainy, as a rule, while sunshine has been the exception.]

THE HONEY-BEE.

A REVIEW OF COWAN'S NEW SCIENTIFIC WORK, BY ERNEST R. ROOT.

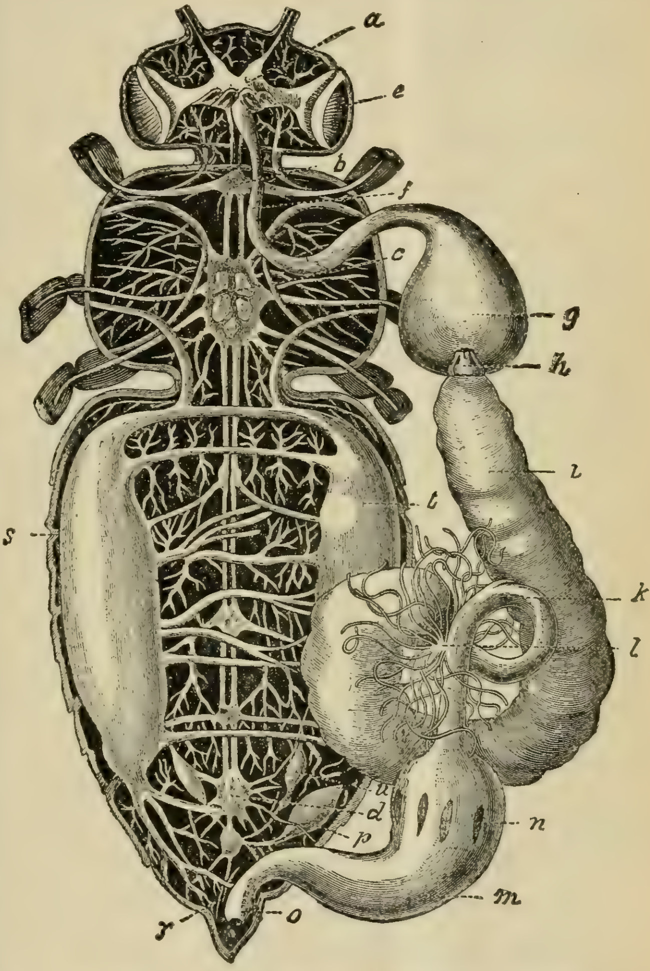
Agreeably to my promise made some time ago, I will now try to give you a taste of some of the good things that appear in that new scientific work entitled, "The Honey-Bee: Its Natural History, Anatomy, and Physiology, by Thomas William Cowan." The book is a small one, 6½ by 4½, and contains 192 pages; but it represents an *immense* amount of painstaking work. It is neatly bound, and appropriately embossed in gilt. It is wholly scientific, and therefore it has little or nothing to say regarding practical apiculture, that part being entirely delegated to a former work of the author's. During my spare half-hours in the evening I have been studying the work with a good deal of pleasure. It is not a book that can be read like a story, but it is one that requires attention and careful study. Unlike some of the larger works, it is condensed, but still seems to cover the most that is important from a scientific point of view regarding our little friends the bees.

One thing that struck my eye particularly, was the beautiful frontispiece engraving, showing almost the entire anatomy of the bee; and I became so much interested in studying it that I here reproduce it for the benefit of our readers.

Now, if you will have a little patience I will try to give you the gist of my reading, and at the same time avoid the use of scientific terms, so far as possible. I may remark, in passing, that the anatomy of the bee is, in many respects, similar to that of the human body; and in describing the various organs and functions I will endeavor to call attention to those that are similar in our own frames.

I will first call your attention to the alimentary canal—that is, the organs of digestion and assimilation. What is digestion? Our author says, "It is the separation of the nutrient part of food from the non-nutrient, and the conversion of the nutrient into a liquid fit to mingle with the blood, and thus nourish the body of the insect." We all know how the bee gathers up his food through his wonderful and delicate little tongue. It then passes into a little tube just below the point A, in the engraving, and is called the œsophagus, or gullet. We find a similar organ in our own bodies, leading from the mouth and communicating directly to the stomach. This œsophagus passes through the waist of the bee, or thorax, as it is called, and to the honey-stomach G in the abdomen. It is in this little sac, although it can hold but a tiny drop at a time, that millions and millions of pounds of nectar are carried annually and stored in our combs. This sac G is located in the fore part of the abdomen, or "hinder" part of the bee, as the boy said.

Several years ago I had a curiosity to know what the bees were working on. I suspected that they were gathering juices from over-ripened raspberries on the vines. In order to satisfy myself I grasped a bee by her waist and abdomen, and pulled until the parts were separated, and then was revealed the little honey-sac, which had disengaged itself from the abdomen. This contained a light purple or wine-colored liquid. The size of this honey-sac, as nearly as I can recollect now, was a good big eighth of an inch; and I should remark that the bee had all that she could contain in her little pocket. Cheshire says that, when the honey-sac is full, it is ¼ of an inch in diameter. This would agree with my observations.



SECTION OF BEE, SHOWING ITS INTERNAL ORGANS.

STOMACH-MOUTH.

The next thing that engages our attention is a sort of valve, which has been call the stomach-mouth, and is located between the honey-stomach and the true stomach; viz., at H. This is one of the most interesting of organs; and I suppose that no part of the internal anatomy of the bee has been studied more, theorized about, dissected, and examined, than this delicate and beautiful little valve. At H its true structure does not appear. It has been likened in appearance to a bud just about to open. It is a sort of valve, fringed on the inside with rows of bristles, or hairs, the object of which seems to be to separate the pollen grains from the nectar, the former passing into the stomach L. Without special engravings which I may yet copy from Mr. Cowan's book, I can not explain exactly the manner in which this valve performs its functions.

TRUE STOMACH.

This corresponds to the stomach in our own bodies, and performs the same function in the way of digestion in converting the nutrient particles of the food into blood. The inside walls of the stomach have certain cells which perform certain offices; but without more definite engravings it will be impossible to describe them in detail.

The next organ is the small intestine, or, as it is sometimes called, the "ilion." In the human body the small intestines are much more elaborate. It is in this that the food, after its digestion, passes, and where, by absorption, the nutrient particles not already absorbed pass into the blood, and so on throughout the system.

You will notice, also, at L, some small radiating filaments. These are called the malphygian tubes. It is not certain what their office is, but it is thought that these are the urinary organs.

At the end of the small intestine, K, you will notice an enlargement, M. This is what is called the colon. Those who have been studying the water-cure remedy, as given in GLEANINGS lately, will know something what this is in the human body. Although the appearance of the colon in the bee is different from that in the human body, yet its functions are very much the same; and if allowed to become dammed up by excreta (that is, by retention during winter) it is liable to cause disease in the bee, just the same as in the human body. On page 112 Mr. Cowan says:

> From the colon, what remains of the undigested food is expelled by the anal opening (frontispiece, *o*). For this purpose strong muscles exist, by which the colon is compressed and the excreta ejected.
>
> The quantity of the excreta voided, usually of a dark brown color, is regulated by the nature of the food; bad honey, an improper substitute for honey (such as glucose) producing a larger amount, while good honey and good syrup produce less, a larger proportion of it being digested and absorbed. It is, therefore, important that bees should have good food, as, in a healthy condition, workers never void their fæces in the hive, but on the wing. In the winter it is retained until voided on their first flight.

So you see, then, that bad food makes mischief, just the same as it does in the human body, and it is in this that the overplus of fæces is stored during winter.

HOW THE BEE "MAKES" HONEY.

After the nectar is gathered, it is then transferred from the tongue to the œsophagus and thence to the honey-stomach, G. It has been shown repeatedly by experiment that there are a great many more pollen grains in the nectar than in honey; hence the little stomach-mouth H comes into play in separating the grains from the mouth. On arrival at the hive, the bee regurgitates—that is, expels the contents of the honey-sac into the cell; but during its stay in the honey-sac the nectar has undergone a change; that is, it has been converted, says Mr. Cowan, from the cane sugar of nectar into the grape sugar of honey, by the agency of a certain gland. This sustains the position held so persistently by Prof. Cook, and his view is doubtless correct; for when two such doctors agree, and cite the authority of almost all of the eminent scientists of Europe in its support, the rest of us will have to fall into line.

But the bee may not regurgitate the honey, for it may pass directly into the chyle-stomach. We see, therefore, that, when a swarm issues, the bees, after filling their honey-sacs to their full capacity (a very small drop), can carry with them a supply of food to last them for several days; and even while on the wing, through that little stomach-mouth, H, they may take nourishment. So much for the alimentary canal, its office in digestion, and the honey-stomach.

THE NERVOUS SYSTEM.

Let us now turn our attention to the nervous system. By referring to the engraving you will see parallel and medial lines passing the entire length of the bee, and finally communicating with the brain A. Along at irregular intervals will be seen thickened masses called "ganglia." These are really little brains, and, as in our own bodies, preside over the involuntary muscles. The largest ganglion is the brain, at A, and is the seat of voluntary action and intelligence. One is surprised in reading through chapters 10 and 11 of Mr. Cowan's work, how thoroughly scientists have studied the structure of the nervous system as found in the bee. Even the tiny brain has been dissected, and its various functions pointed out—that is, what parts communicate with the antennæ, what part with the eyes, etc. I was greatly interested, in looking over the sizes of the different brains found in different insects. I quote here a paragraph from page 70:

> It is generally admitted, that the size of the brain is in proportion to the development of intelligence; and Dujardin, who made careful measurements, gives the following sizes: In the worker bee the brain is the $\frac{1}{174}$ of the body; in the ant, $\frac{1}{286}$; the ichneumon, $\frac{1}{400}$; the cockchafer, $\frac{1}{3920}$; the dytiscus, or water-beetle, $\frac{1}{4200}$.

In man the proportion is 1 to 40, I believe; but we all know that he is of the very highest order of intelligence. However, we are not very much surprised to learn that the bee has the largest brain of any of the insects, exceeding by far even that of the ant, whose intelligence we have admired over and over again.

THE RESPIRATORY SYSTEM.

It is also interesting to inquire how the bee breathes, and chapter 8 points out to us the wonders of the nervous system in the bee. By referring to the engraving given, we observe a couple of large air-sacs, called the "trachea," and correspond somewhat to the lungs. These are located on either side of the abdomen, as at T. These are divided and subdivided into smaller trachea, and these in turn ramify all through the entire body. Instead of fresh air being received in at the mouth, as with us, fresh supplies are admitted through 14 little mouths called "spiracles." Ten of these are located on the abdomen—five on each side—and are situated just about on the margin of the scales, between the dorsal and ventral segments. Four others are situated on the thorax, or waist, two on each side. You may, therefore, decapitate a bee and he will continue breathing as before. If you place a pencil dipped in ammonia near his body, the headless insect will struggle to get away; and if the pencil touches his feet, the ganglia already spoken of communicate the sensation to the other ganglia, and at once all the feet come to the rescue to push off the offending object, or, it may be, to take a closer hold so the sting may do its work. Besides that, if bees are daubed with honey they will die very soon from strangulation, because these little mouths or spiracles are closed. A bee may swim around in a trough of water, and, though his head be entirely out, he will drown just the same, because these spiracles, or breathing-mouths, are submerged under water. On a hot day, if the entrance of a hive be closed, the bees will soon begin to sweat; and, thus becoming daubed, the delicate spiracles are closed, and the bees die.

ROYAL JELLY, AND WHAT IS IT?

Nothing in the book interested me more than the discussion in chapter 18 in regard to the royal jelly. Cheshire insists that it is a *secretion* from one of the glands; but Prof. Cook has maintained that it is the product of the chyle-stomach; and Mr. Cowan proves conclusively that this is the right view, and eminent authority is not wanting to sustain them.

This chyle is produced in what is called the chyle-stomach, shown at L. in the engraving; and worker larvæ are fed on this concentrated food for three days, after which they are weaned. "On the fourth day this food is changed and the larva is weaned; for the first pap has a large quantity of honey added, but no undigested pollen, as Prof. Leuckhart had stated. The drone larvæ are also weaned, but in a different way: for, in addition to honey, a large quantity of *pollen* is added after the fourth day." And right here I can not do better than quote from Mr. Cowan:

> Microscopic examination showed that, in the queen and worker larvæ, there was no undigested pollen; whereas in the drone larvæ, after the fourth day, large numbers of pollen grains were found. In one milligram, no less than 15,000 pollen grains were counted, and these were from a number of different plants. . . . This work of Dr. Planta's, we think, conclusively proves that the food is not a secretion, and that the nurses have the power of altering its constituents as they may require for the different bees. . . . Royal jelly is, therefore chyle food, and this is also most likely the food given to the queen-bee. Schonfeld has also recently shown that drones are likewise dependent upon this food, given to them by workers, and that, if it is withheld, they die after three days, in the presence of abundance of honey. This, he thinks, accounts for the quiet way in which drones perish at the end of the season. It will now be easily understood, that, if weaning of the worker larvæ does not take place at the proper time, and that the first nourishing food is continued too long, it may be the cause of developing the ovaries, and so produce fertile workers, just as the more nourishing food continued during the whole of the larval existence in the case of a queen develops her ovaries, or even in the absence of a queen the feeding of workers on this rich food may tend to have the same effect. This, then, is the solution of royal jelly and brood food.

I would say, in conclusion, that I enjoyed greatly studying up this subject. It used to be an old passion of mine; but it took such an immense amount of time, and caused such a severe strain on my eyes that I abandoned it.

In my effort to put the whole of this into common parlance, I may possibly have stated some things incorrectly. If so, I shall be glad to have our author or Prof. Cook set me right.

THE CLOVER EXPERIMENT.

E. E. HASTY TELLS US HOW HE PROSPERS IN TRYING TO DRIVE DAME NATURE.

Friend Miller pokes me up with a "straw" about those clovers. Yes, doctor, I've got an improved clover (that is, part of the time I have it); but, just to pester me, it almost totally refuses to bear seeds. And the seedlings, when I do get a few, about nine-tenths of them backslide. The florets of this specimen of clover are double; and, as abnormal double flowers are usually seedless, my tribulations are not unaccountable happenings, but the regular course of the Cosmos. Never mind; just wait till we see what we shall see.

I have some fear that my phenomenon does not secrete nectar as freely as the unimproved clover. I do not see bees on it. But then, I believe bees rather seldom go to *one plant* of a thing that is new to them. I have never yet had even a square yard of it in bloom at one time. So far as length of tube is concerned, it seems to be short enough.

I have had over a dozen sub-varieties of clover in tow; but one by one I have dropped them, until I now have but four in training. You see, it's like trying to drive the hens away from their home. You can drive them a few rods away from the barn very easily; but the further you go, the more desperate they get in the determination to get by you and go back again. E. E. HASTY.

Richards, O., March 31.

STRAY STRAWS FROM PROF. COOK.

SHALL WE GATHER FIGS FROM THISTLES, OR WHEAT FROM CHESS? ETC.

That was a very happy thought—securing the "Stray Straws." Good, too, to use this valuable letter on first page, as it saves time; for your readers will soon pick for these grain-laden straws the first thing.

Does not Dr. Miller know that Michigan and Rhode Island are both experimenting with bees at their stations? They are both doing something with bees, and, I hope, for bee-keepers. Was this among your "Don't knows," doctor?

It is nearly as easy to quiet bees by the use of carbolic acid as by the use of smoke. If such practice antagonizes "foul brood," those interested may well adopt it. It is surely worth a trial by those who are sufferers.

Why does a writer in one of the recent journals say that it is proved conclusively that "foul brood" results from chilled brood? I did not suppose that there was a shadow of proof of that statement. When figs come from thistles, then we may expect foul brood from chilled, and I think not before. That "foul brood" should be more common north, is easy to explain. Disease always reaches for those of feeble health. That the microbe which attacks our bees should form no exception is easy to believe. The bee is native to a warm clime. North it is apt to suffer from a rigorous climate—to become enfeebled, and so form a ready seed-bed for this dread malady.

Dr. Miller places a minute interrogation-point, inferentially at least, after my statement that honey is a safer food for bees in quiet than is cane sugar. I know of no experience, doctor, that contradicts it. Do you? Suppose you feed cane sugar in the fall. When the bees are active they digest it and place it in the cells. They do this when active, unconfined, and able to digest it. The old saying, that "dyspepsia hates a buck-saw," applies here. Shut the bees up and feed cane syrup, and you have a different condition. I believe cane-sugar syrup, fed in the fall, is superb for a winter diet for bees; but fed in the winter, while they are precluded from all exercise, I should fear it. As Dr. Miller intimates, there is that which is called honey, which we would not care to eat, and better not compel our bees to eat, at least during the time of winter confinement. I am surprised at Dr. Miller's big (?) regarding a cure for the "nameless bee-disease." I supposed it quite settled, that removing the queen cured that ailment; but here I quote the doctor: "I do not know."

I am glad to hear Mr. Cowan's book praised. It is excellent. He gives the history of most of our discoveries, and withholds no credit. He does not say that the upper head glands secrete the larval food, but, as I showed by actual experiment, a year ago, the larval food is really chyle, or a product of true digestion in the true stomach. I fed bees syrup with pulverized charcoal in it, and found the latter in the royal jelly. This could not occur if royal jelly were a secretion.

Our bees in the cellar seem to be doing very nicely. We must praise the past two winters for bees, even if we can not boast of the summers and their product. A. J. Cook.

Agricultural College, Mich.

[At the Detroit convention somebody asked whether chilled brood produced foul brood. I answered, "Not unless corn grows where corn has never been planted." R. L. Taylor added, "Or when wheat turns to chess." As good authority as R. L. Taylor gave us experiments that seemed to prove most positively that sugar syrup is a safer winter diet than honey, and I supposed this was well settled more than ten years ago. I have fed bees syrup all winter long, both outdoors and in the cellar, just on purpose to see whether it would hurt them. They came out strong and healthy. I have, however, had bees die from spring dwindling when it looked somewhat as if feeding during cold weather aggravated the malady. That experiment with pulverized charcoal in the syrup was a bright idea. I congratulate you on it, friend Cook.]

◆

ILLINOIS PROPOSES TO HAVE A LAW TO PREVENT SPRAYING FRUIT-TREES WHEN IT MAY POISON THE BEES AND HONEY.

THE ADVANTAGE OF HAVING A LIVE BEE-MAN IN THE LEGISLATURE.

Friend Root:—Inclosed please find two bills which I have had the pleasure of introducing into our Legislature. Should they meet with a favorable consideration from you, any comments through Gleanings will be highly appreciated by myself and the many friends desirous of their passage. J. M. Hambaugh.

Springfield, Ill., Mar. 31.

37th Assem. HOUSE—No. 607. Mar. 1891.

1. Introduced by Mr. Hambaugh, March 26, 1891.
2. Read by title March 26, 1891, ordered printed, and referred to committee on horticulture.

A BILL

For an act to protect bees from poison through the spraying or otherwise treating of fruit or other trees, shrubs, vines, or plants, with London purple, Paris green, white arsenic, or other virulent poisons, while the aforesaid trees, shrubs, vines, or plants are in bloom.

Whereas, spraying of trees, shrubs, vines, or plants at the proper time greatly improves the conditions favorable for a crop of fruit, and

Whereas, spraying should never be permitted until the blossoms have fallen from the latest blooming trees, and

Whereas, the insects injurious to fruit do not make their appearance until about ten days after the bloom, and

Whereas, the spraying of trees, shrubs, vines, etc., while the same are in bloom poisons the bees and seriously injures the bee-keepers and reduces the signal benefits to the fruit-growers, who have repeatedly demonstrated that the bees ensure better crops, therefore

Section I. *Be it enacted by the People of the State of Illinois, represented in the General Assembly*, That it shall be unlawful for any person to spray any fruit-trees, shrubs, vines, or plants, with Paris green, London purple, white arsenic, or other virulent poisons, or to scatter upon such trees, shrubs, vines, or plants, powdered London purple, Paris green, white arsenic, or other virulent poisons, while such trees, shrubs, vines, or plants are in blossom, and so may be visited by honey-bees in quest of nectar or pollen.

And that any person who shall spray such trees, shrubs, vines, or plants with London purple, Paris green, white arsenic, or other virulent poisons, or shall scatter the poison upon the same while in blossom, shall be deemed guilty of a misdemeanor, and for the first offense shall be punished by fine in any sum not less than five dollars, and for the second offense by fine in any sum not less than twenty-five dollars; and, in default of payment of the same, by imprisonment in the county jail not more than ninety days.

Sec. II. The fines resulting from the operations of this statute shall be paid to the State Treasurer by the court imposing the same, and be placed by said treasurer to the credit of the Illinois Bee-keepers' Association to be used by said association in promoting and developing the industry of bee-keeping in this State.

Sec. III. The Illinois Bee-keepers' Association may in its discretion employ a competent person as an executive officer for service in enforcing the provisions of this statute, whose powers, duties, and title shall be prescribed by said bee-keepers' association, and whose compensation shall be fixed by said association subject to the approval of the Governor. Said executive officer shall be removable at the pleasure of said association.

Sec. IV. The fines resulting from the operation of this statute, or so much thereof as may be necessary for the purposes named above, are hereby appropriated to defray the cost and expense of the work contemplated by this act, to be paid by the State Treasurer from funds not otherwise appropriated, upon warrants drawn only upon itemized vouchers, and bills signed by the president of the Illinois Bee-keepers' Association, countersigned by the secretary thereof, and approved by the Governor. *And provided, further*, that in no event shall the State of Illinois be held or become liable in any amount in excess of the revenue obtained through the operations of this statute.

37th Assem. HOUSE—No. 599. Mar. 1891.

1. Introduced by Mr. Hambaugh, March 25, 1891.
2. Read by title March 25, 1891, ordered printed, and referred to committee on appropriations.

A BILL

For an act to provide for the participation of the State of Illinois in the World's Columbian Exposition, authorized by an act of Congress of the United States, to be held in the city of Chicago during the year 1893, in commemoration of the discovery of America in the year 1492; and for an appropriation to pay the cost and expense of the same.

Whereas, the large revenues derived annually from the sale of honey by the bee-keepers of Illinois make this important industry worthy of the fostering care of the General Assembly, and

Whereas, a creditable apiarian exhibit by the bee-keepers of Illinois at the World's Columbian Exposition to be held in Chicago in 1893 will call marked attention to this growing industry and greatly assist in the development of the same, and thereby add largely to the material prosperity of the State, and

Whereas, the Illinois Bee-keepers' Association, an organization composed of the leading apiarists of the State, and duly incorporated in compliance with the statutes of this State, have petitioned this General Assembly for an appropriation to defray the expenses of making an exhibit of bees, honey, apiary supplies, and appliances at the World's Columbian Exposition in 1893, therefore

Section I. *Be it enacted by the people of Illinois, represented in the General Assembly*, That there be and is hereby appropriated to the Illinois Bee-keepers' Association, out of any money in the treasury not otherwise appropriated, the following sums, to-wit: For the payment of the expenses of making an exhibit of bees, honey, apiary supplies, and appliances at the World's Columbian Exposition to be held in Chicago in 1893, the sum of five thousand dollars, or so much of said sum as may be required to make a creditable display.

Sec. II. The Illinois Bee-keepers' Association may in its discretion employ a competent person as an executive officer for service in preparatory work and care of the State Apiarian Exhibit, whose powers, duties, and title shall be prescribed by said Bee-keepers' Association, and whose compensation shall be fixed by said association, subject to the approval of the Governor. Said executive officer shall be removed at the pleasure of said association. Any member of said Bee-keepers' Association, other than said executive officer, rendering service in connection with said State exhibit, by instruction of said association may receive as compensation therefor only necessary expenses and cost of transportation while actually employed in such service.

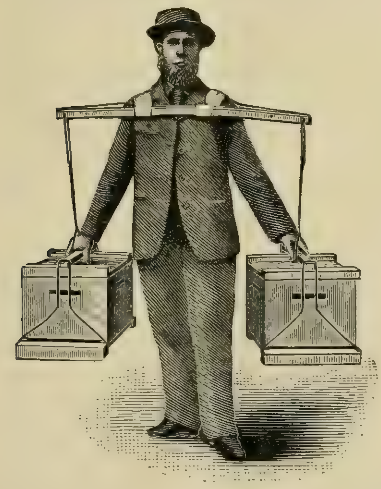
SEC. III. The sum of five thousand dollars, or so much of it as may be necessary for the purpose, is hereby appropriated to defray the cost and expenses of the work contemplated by this act, to be paid by the State Treasurer from funds not otherwise appropriated, upon warrants drawn by the Auditor of the State, which warrants shall be drawn only upon itemized vouchers and receipted bills signed by the president of the Illinois Bee-keepers' Association, countersigned by the secretary thereof, and approved by the Governor: *And provided further*, that in no event shall the State of Illinois be held or become liable in any amount in excess of the sum hereby appropriated.

[We publish the above for precedent for action on the part of other States of the Union. If your neighbor should undertake to spray his trees while in bloom, I think if you would show him the above he would be very likely to assent to the justice of your request, and forbear.]

M'FARLAND'S DEVICE FOR CARRYING HIVES.

HOW TO CARRY HIVES IN AND OUT OF THE CELLAR; A SEASONABLE ARTICLE.

Having not always found it an easy matter to procure good efficient help to assist in carrying bees to and from the cellar, I began some time ago trying to invent some way by which I could do the work more speedily and easily. Sometimes I would endeavor to do this work alone, carrying one hive at a time; but I found a hive of bees rather awkward to get hold of to carry any distance, and very tiresome when one has 100 or more colonies to place in winter quarters, as I have had. At other times I would place two or three colonies on a board, and take them to the cellar or to the yard, with the aid of an assistant. I found these methods quite unsatisfactory, as well as the plan of taking two men to carry in one hive at a time, which was not expeditious enough, and too expensive. I remember, when I used to work in the maple-sugar bush, we had sap-yokes to support and balance the pails on either side, and it occurred to me that this yoke might be adjusted for moving hives. After some little thought upon the subject I studied out the arrangement as you see herewith illustrated.



M'FARLAND'S DEVICE FOR CARRYING HIVES.

The yoke consists of two bent pieces of wood, fastened together in such a manner that, when adjusted, one piece is in front and one behind the carrier, and the weight comes squarely upon the shoulders by means of two wide pieces of webbing, making a very easy support.

The clamp attachment to the hive is of my own construction. I have loose bottom-boards, similar to the Dovetailed hive, and this clamp springs on to the bottom-board at the front and rear ends of the hive. It is very quickly put in place and taken off. I have used this yoke and clamp for some time past, and find it the most convenient contrivance for moving hives I have ever seen. By its use one man can do the work of two, do it easier, and with much less jar to the bees. F. H. McFARLAND.

St. Albans, Vt., March 4.

[Your device, although very old in principle and application, is good. Whether any one else has suggested a similar thing for carrying pairs of hives, I do not know. It puts the weight at the right spot, directly across the shoulders; and a man can carry more comfortably a weight suspended from the shoulders than from any other point. The arms come just right to steady the burden and equalize the possible difference in the weight of two hives. The only objection that I see to it is, that it would be a little unhandy about getting through narrow doorways, and possibly down steep cellarways. A great many cellar-steps are so constructed that the head comes about a foot above the top of the doorway when standing on the last step. It is so at my house; and I imagine that, with a couple of hives on the yoke, it might be a little inconvenient to stoop down and pass in. Still, I propose to try it. For upground repositories I think your device will work very nicely; and no doubt it can be used advantageously for *most* cellars having more convenient means of ingress and egress. This will appear when most of our friends will be thinking of carrying their bees out of the cellar, and it will give them time to make an implement and try it.] E. R. R.

WATER CURE FOR NASAL CATARRH, ETC.

WASH YE, MAKE YOU CLEAN.

Friend Root:—I read your article on water cure, in March 1st GLEANINGS, with a great deal of interest. I think you are right in exposing this great swindle, and also in giving to the people a simple remedy of such great value. The great judgment only can tell the amount of good you are doing in this way.

There is another subject I should be glad to see you take up in GLEANINGS, and that is nasal catarrh. It can be treated and cured in the same way you describe. Dr. Pierce, of Buffalo, N. Y., gets up his nasal douche, a tin holding perhaps a pint, with a tin tube near the bottom (on the order of the honey-gate in an extractor). Take a small rubber tube, some two feet long; slip one end on the tin tube and the other end on a little nozzle to go into one nostril. Dr. Pierce, of course, sells medicine for catarrh which is good, but not necessary in every case. Simple warm water, with a little salt in it, is good, and this, with a suds made from castile soap, has cured some bad cases. Put the liquid in the can; set it overhead; hold the rubber tube so the liquid can not flow; insert the nozzle in one nostril, breathing through the nose, and let the liquid flow. It will flow up one nostril and down the other, cleansing and healing the nasal passages as nothing else can. Use the warm salt water and the suds (warm of course) each once a day, and it will cure any ordinary case. J. H. Hill.

Venice, Fla., March 21.

[Well done, friend Hill. While I was looking over Dr. Kellogg's book in regard to the Hall discovery, I noticed the apparatus you mention illustrated there. A few days ago I had quite a severe cold, and toward its winding up it seemed to me that it would just be fun to get Dr. Kellogg's apparatus and give my nostrils a good rinsing out. I did not know just how to go at it, however, and I was afraid I might get strangled, and therefore I let it go. Now you have made it as plain as A B C. But are you positively sure, my good friend, that there is any thing at all needed but pure water? Just listen. A poor woman was grievously afflicted with some kind of rheumatism. She and her husband scraped up money, and she went to a celebrated water-cure. Sure enough, she began to improve right away, and in a few weeks she was comparatively well. After she went back home, however, the old symptoms returned, and finally she was about as bad as before. It cost an awful lot of money to get to the celebrated springs, and they could not afford it. As a drowning man catches at a straw, however, one of the twain, I do not remember which, suggested that she take a daily bath with the water that was at hand, using it in the same manner she used the water at the medical spring. What do you think the result was? Why, a daily bath, with simply common water, relieved her of her trouble just as well in her own home as it did at the expensive watering-place. By the way, how much does it cost to go to a high-toned medical spring, and take a course of treatment, paying the doctor, traveling expenses, high-priced board, and all that? May be some of you can tell. And is it not humiliating to be obliged to confess that the whole thing amounts to nothing more nor less, *finally*, than the old-fashioned water-cure treatment of Fowler & Wells, published so freely all over our land more than forty years ago?

On page 273 of our last issue, a friend, who has been an invalid for years, tells us about using flaxseed in connection with flushing with water, for cleansing the small intestines as well as the colon. By the way, friends, I have been expecting all along that somebody would take exceptions to the way in which we were discussing not only subjects that are usually considered delicate, but matters that might be considered by some out of place, or lacking in dignity. Well, there has not been a single such protest that I know of, unless it was a little bit of pleasantry now and then. I suppose the reason is, that so many of us have been longing for relief in this very line, and perhaps longing for any thing that would give us aid in this matter of keeping the human frame divine sweet and clean, fit places for the dwelling of the Holy Spirit. Well, I have been eating flaxseed, as recommended, and I am rejoiced to tell you that, in my case, it answers the purpose perfectly. Please bear with me if I tell you just why I feel so certain that it is a valuable adjunct. I drank a great lot of hot water about seven o'clock in the evening—so much, in fact, that it made me feel uncomfortable to some extent through the night. Then in the morning I commenced, the first thing, eating flaxseed. It is not the pleasantest stuff to eat, by the way and I kept thinking, while I chewed it up fine, that I should prefer to have it cooked in some way, if it would answer the same purpose. I used the flushing remedy the night before, so that I could be sure that it was the flaxseed that did the cleansing if there was any. Well, within an hour after taking it I began to feel its effect. And now comes the whole point of my story. The offensive smell that I told you of when I first began the flushing, has not been noticeable for perhaps months. On this particular occasion, however, the old familiar and exceedingly offensive smell was present, indicating unmistakably that the flaxseed had loosened up and brought away accumulations that had been perhaps for a long while lodging in the small intestines, and matter that the water itself had not reached. We are surely making progress; and is there any other subject, in the whole range of human intelligence, of more moment and more importance than this one of making ourselves clean—of following the injunction found in the Scripture texts which I have so often quoted to you—"Wash ye, make you clean"? A great wave is going through our land, and possibly other lands, in this direction of thorough washing; and I tell you, it is a hopeful sign. When we bend our energies, and the intelligence of the thinking people of the world toward this matter of cleanliness, and of making our bodies not only clean without but clean within, wherever pure water can be made to go with the aid of all modern appliances, I tell you we are on the highway to some great achievement. One happy thing about it is, that it is within the reach of all—the poorest as well as the richest, and there should be no excuse hereafter for uncleanness in any shape or form. Our country has been given to booms—first one thing and then another. Sometimes these booms are wholesome and sometimes not. But if there is going to be a great big boom all over the world in washing the body more thoroughly than has ever been done before *since the world began*, it is certainly going to prove to be a good thing, and a great many steps heavenward; for "cleanliness is next to godliness." Let us wash our bodies, our feet, our hands, our heads, our ears. Small boys can have a share in this latter. How my good mother did used to exhort and reprove me because my ears and finger-nails were not clean! After we have got the ears and scalp washed and cleansed, then our *noses* must be overhauled, as our friend Hill advises. Then let us provide plenty of tooth-brushes, and wash our mouths and our teeth. Very likely some nice soap with the soft water, or perhaps some clean sand or charcoal dust, might help along. We want flesh-brushes and nail-brushes as well as tooth-brushes. And, by the way, who knows whether we shall not succeed in doing away with this disagreeable thing of a bad-smelling *breath* that afflicts some people? My dear friend, how many do you know among your acquaintances whose breath is offensive? May be you have been told that *your own* breath is offensive. If so, what would you give to have it sweet, pure, and clean, like the breath of a baby? Well, I am inclined to think that, with the information that has been given in these pages of Gleanings, the whole thing may be accomplished. Let us first put the whole body in the right shape with energy. You see, your friends do not always tell you when your breath is offensive; but your wife will; and next time you give her a kiss (I really hope it will not be three or four weeks before you do), just ask her to tell you whether or not your breath is improving. Oh! by the way, if you are in the habit of using tobacco, after you get cleaned up nicely, inside and out, you will be in excellent trim to leave off the foul weed. Why, it would be a great pity to defile the holy temple after having been made clean in the way we have indicated. And all this great work in cleanliness, and its resulting health, is to be accomplished in your own home, by means of pure water, pure air, plenty of sunshine, and all the rest of God's free gifts. What will the doctors do? Why, bless you, we will pay them a good salary, and appoint them as inspectors to overhaul us, say twice a week, and see that we are doing our duty on the above line.

GIVING AWAY THE WATER-CURE SECRET AMONG THE FARMERS.

There is an agent in our neighborhood selling Dr. Hall's recipes. He hasn't sold any in this neighborhood, for I haven't been very still. The farmers are organized all over this part of the country, and it is an easy matter to get news around in a very short time.

Solitude, Ind., March 17. J. P. UTLEY.

WHAT A DOCTOR SAYS OF THE WATER CURE, AND ITS OLDNESS.

We have one of Dr. Hall's agents here selling the "secret" for $4.00. I am a graduate of the Hygeio-Therapeutic College, of New York, of the class of 1865, and have used the drugless remedy for 30 years. When I first heard of Dr. Hall's "secret" I said I could guess what it was; and I told the agent that, if there was one part of the water-cure system of more importance than another, it was the use of water injected into the colon. I am not practicing now, but I could give numerous instances of the relief administered by the syringe. I know of no better motto for health than "Trust in God, and keep your bowels clean." EZRA YODER.

Paola, Kan., March 11.

WATER CURE—USING IT TO EXCESS.

I think you extremely modest in putting the internal water treatment before the public. While others, through greed and avarice, are making money selling this as a new and secret remedy, I am glad that you are so magnanimous as to print and furnish it for distribution free of cost. Only lately I paid four dollars just to find that one Hall had learned this treatment about the same time I did. Now a word of caution. Old men sometimes ride hobbies, and it is said that old cranks are the worst of cranks. Don't come to regard this as a universal panacea. Don't recommend it on all occasions and for all persons. It is possible to practice it to such an extent that nature will cease to perform her functions, and the person be left dependent on artificial means for the operations that nature is intended to produce. I suppose you remember a case reported of a typhoid patient dying by using this remedy. Please send me 50 to 100 copies of the treatment.

Philipsburg, Pa., March 10. JNO. D. GILL.

WATER-CURE TREATMENT; WASHING OUT THE STOMACH.

I wish to say a word about that "drugless remedy." There is one point you have not touched upon. An acquaintance of mine was sick for a long time with a stomach trouble. The usual prescriptions were administered with but little effect. Finally the doctor brought a long rubber tube, about three or four feet long, with a funnel at one end. The small end was introduced into the stomach, and warm water poured into it until the stomach and tube were full. In a short time the funnel end was dropped low down over a proper receptacle, and the contents of the stomach all came out through the tube. All that was not digested was removed; and when food was taken again, the man had a clean stomach to start on, and his improvement was immediate and marked; and thus what drugs failed to effect the water accomplished. This doctor gives the same treatment to others afflicted in like manner. I suppose this means is known to you, but I think it should be mentioned in connection with your other "wash and be clean" arrangement. I know that the use of water will relieve the painful effects of piles, and am not sure but a frequent application will result in a permanent cure. RAMBLER.

LADIES' CONVERSAZIONE.

MRS. HARRISON GIVES SOME ENCOURAGING WORDS.

THE LADIES' PARLOR.

I had begun to think that GLEANINGS was not as good as it used to be. When a new one came I would look it all through to see if any of the ladies had written, and felt lonesome and disappointed when I found nothing from them. I do not believe that I take much interest in a bee-paper where the other sex do *all* the writing. The April 1 No. of GLEANINGS was a delight, a regular "conversazione." How nice in the editor to fit us up a parlor to do our talking in!

I am personally acquainted with all in attendance at the last "conversazione," with the exception of Mrs. Grubb, and to her I extend my ☞ in token of friendship, and I should be glad to welcome her to our bee-conventions or at my own home.

It is refreshing to hear from "Our Clearing" again, and hope that Nellie Linswik will come often and bring with her her sister, who wields so graceful a pen. I've long thought that I could not go to that great city of Chicago if it were not for my dear friend Mrs. Stow to guide me and keep me from being run over by the grip cars which glide upon one unawares. And now that I am the eldest, I will take the big chair, and Mrs. Axtell can recline on the sofa, as she is an invalid, and we will have a talk about seats.

RESTING-PLACES IN THE APIARY.

The girls will no doubt say, "Umph! *I* don't want any." My advice is, that you had better try them, at least. I've learned to do a great deal of work sitting that I could not do at all if I did not. A woman complained to a very self-reliant neighbor that she was not able to stand up to mix her bread. She replied, "Sit down, then." That was not the kind of answer she expected or desired, and she would not be apt to apply to her again for sympathy. Our hives stand upon the ground, raised at the back the height of two bricks, and one in front; and if I had to remove the combs from one hive to another standing, I could not do it; but I can enjoy doing it sitting. Our hives are eight-frame Langstroth, with cap and loose cover. The cover is two boards, grooved together and cleated. I've received a great many curtain lectures from turning these caps upon their sides and sitting upon them. I'm told that I rack them, which I do when the ground is uneven; and once I found myself sitting down suddenly upon four little boards. "If you *will* sit upon the caps, why don't you put the cover on and sit that way?" The cap is lighter, and of a height to suit me better. If I should get down upon my knees at the side of a hive, the rheumatism would find it out in an hour, and move in. If I get upon my knees around a hive, I put down a cover and kneel upon it. It would be inconvenient to carry a chair around, and the height would not suit me as well as the cap does. I do not believe I could sit upon a cover, as Ernest Root does. Perhaps our young ladies can. I use hives for seats in different places around the apiary, under the green ash, when I'm watching for swarms, and sit down to eat a bowl of pounded ice, or in my office scraping out hives, which is under the leafy cover of a grape-arbor.

I have, in my rag-bag, a ripped-up pair of brown linen drilling pants. I intend to make a pair of mits of these, extending to the finger-tips. I know I can handle frames much quicker with these on, and the bees do not sting through linen. Their stings appear to slide over it and not penetrate it.

A GOOD DINNER.

That good dinner that Mrs. Axtell speaks of is a desideratum during the busy season of the apiary. But how to get it when there is no reliable help in the house is the question. I find that I can not leave food cooking over a gasoline stove, as well as over a coal fire. It is so much hotter, it boils dry sooner. If it is a cool morning I make a fire in the cook-stove, bake graham gems, and, if I want to cook snap beans, I put them on over the remaining fire, and they will cook slowly for hours; and if it goes out I light the gasoline to finish. Vegetables that cook quickly, like green corn, asparagus, etc., I get ready in the early morning, and cook over the gasoline. MRS. L. HARRISON.

Peoria, Ill., April 5.

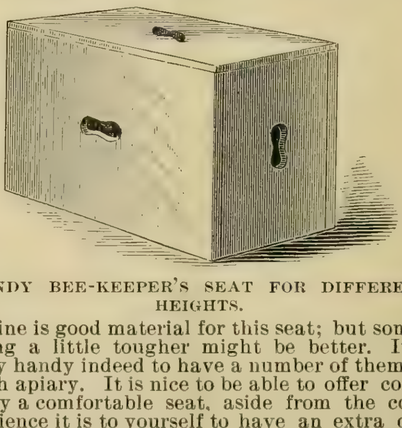
[Ever since this matter of seats has been mentioned in different letters, I have been feeling a little uneasy because I have not told you my own experience. I have several times been on the point of being used up through nervous prostration; and perhaps some of my friends think me notional even now, because I refuse to consider an important matter without first sitting down. The book-keeper will come to me with a list of bills to be paid, wanting my approval. Now, a great many times when I am putting on my nose-glasses I reach instinctively for a seat. As it does not look well for a man to set down and leave a woman standing, I often tell her to sit down too. But she says she does not care for a seat. Well, a good many times I don't; but when I am really suffering from lack of exercise, and when I could walk a mile through the woods and over the fields, I often feel that I should be used up if I did not have some place to sit down before I undertake any mental effort. I know other people don't care as much for a seat as I do, because they do not say any thing about it. But any comfortable place to sit down is to me, when full of care, like a drink of cool spring water to a thirsty man, or like an oasis in the desert to the fatigued traveler. When I get my book written, "How to Doctor People Without Medicine," I assure you that plenty of handy *seats* will be a conspicuous figure in the work. It is not only out in the apiary, but wherever people are employed where they are obliged to *stand still* a good deal, that seats are a saving of strength, and I feel sure, many times, a saving of life. One of the housekeeping journals advised the housekeeper to have handy, light strong stools of different heights. I often go through the rooms where our girls and women are at work; and I not only suggest but *insist* on their having stools to sit down on, when their work admits of it. If I am to show them any thing that occupies more than a minute or two, I want a stool to sit down on; and I want my pupils to sit down likewise. Now, stools sometimes play an important part in matters of more import than business and success in life. Sometimes I feel as if I should like to have a good talk with some of these good friends on their spiritual interests; and oftentimes I know beforehand that they will perhaps evade, and, may be, try to shift responsibility. At such a time I want to *sit down* by them, and I want them to sit down by me, in order that we may *fully* understand each other. Sometimes just the opportunity and circumstances seem to be at hand, and the only thing lacking is a couple of chairs or stools. If I could sit down comfortably, and see my friend also seated in like manner, it seems to me I could speak a word for Christ Jesus in a way that would surely bear fruit and bring happiness to the brother or sister in question. Now, then, who shall say again that a place to sit down is of little consequence?]

A HANDY SEAT FOR THE APIARY.

A PATENTED (?) ADJUSTABLE SEAT.

You ask, Mr. Root, for a description of the seat we use in our apiaries. We have tried a number of different kinds, but the one we have settled upon as the most convenient is simply a box 17x12x9 inches. For the end, take two pieces of ⅞-inch lumber, each piece 11x8 inches. For the rest, use ½-inch lumber, 17 inches long. A box closed on all sides is not very easily picked up. To make it so, put a hole in the middle of one side, 3x1½ inches. For greatest convenience, put one in each side. This makes a strong, light seat, and one that is very easily picked up. It gives us three different heights, which is of considerable importance. Turn the picture on one side, and you will see the seat at a different height.

I don't know why it is, but Dr. Miller and I never want the same height in a seat. He generally sets the box on end, using the 17-inch height, although he sometimes uses it at 12 inches. I prefer a low seat, and, if working at the hive when there is no tiering up, I like the 9-inch height. I can use the 12-inch quite comfortably; but the 17-inch would be very uncomfortable, unless working at an upper story, when it is quite convenient. So you see the advantage of having different heights.



HANDY BEE-KEEPER'S SEAT FOR DIFFERENT HEIGHTS.

Pine is good material for this seat; but something a little tougher might be better. It is very handy indeed to have a number of them in each apiary. It is nice to be able to offer company a comfortable seat, aside from the convenience it is to yourself to have an extra one or more lying around handy. They are quickly and easily made, and almost any bee-keeper will have plenty of waste boxes or other lumber that can be utilized in making them. So the item of expense need not be counted. It's a good time to get them ready now, so as to have them all ready when the busy time comes. The way we came to use them in the first place was by having so many empty glass boxes lying around, which we used for seats; but they were not quite substantial enough with one open side. Dr. Miller always sat on the end; and after being in use for a while they would split, sooner or later, although the ends were of ⅞-inch stuff. Nailing up the open side makes them very strong.

HOW TO LOSE TOOLS.

Do you ever have any trouble losing your tools in the apiary? You are a model bee-keeper if you don't; for brushes, chisels, etc., have a habit of hiding just at the moment you want them most. Dr. Miller is very orderly about his tools (I'm not going to tell you how I am with mine). He usually lays them on top of a hive in plain sight; never on the ground. If he accidentally drops one on the ground, he stops immediately and picks it up, no matter what he is doing. He says if he doesn't he will forget all about dropping it and it is hopelessly lost. But even then, he sometimes loses them. It is funny how you can look for something in vain when it is right before you. If you have any difficulty with yours, an excellent way is to tie your brush, chisel, etc., to your apron, or button-hole, with a good strong cord. Then you are sure of them, and can drop them at will. Dr. Miller had an arrangement which he liked very well. He had a strong cord fastened together so that he could slip it on over one shoulder and under the opposite arm, and the string of each tool was fastened to this cord instead of the button-hole. EMMA WILSON.

Marengo, Ill., April, 1891.

[Your box looks as if it might be real handy, though I would about as soon use a hive-cover. Yet if I were to use that light handy box, with its *patent* adjustable heights, I might like it.

Yes, we do lose things, just the way you speak of; but more often one of our men in the other departments will borrow it without saying any thing about it, because it belongs to the big boss, and that is the last of it. This is one of our serious troubles at the Home of the Honey-bees.] E. R.

MRS. AXTELL DISCUSSES SOME IMPORTANT MATTERS.

CLOTHING THE FEET IN WET WEATHER.

Women's light rubber boots are not enough protection to the bottom of the foot, I think. I like boy's rubber boots better, as one should wear them only when the feet need protecting from dampness. They are a great convenience, even for persons who do not work among bees, to slip on and care for chickens in sloppy weather; and many times they will be found useful and healthful.

WHY QUEENS ARE SOMETIMES DESTROYED AFTER HAVING THEIR WINGS CLIPPED.

Some say they lose so many queens if they clip their wings. One reason, I think, is because the scissors were not strictly clean, and had been used for other purposes, and so left a scent on the queen, as bees have a very keen smell; or the fingers were not perfectly clean, or the wing was cut too close, or she was clipped during a honey-dearth when bees are cross. I believe that bees, oftener than we think, kill or ball their queen when handled in a honey-dearth (even when the queen is not touched), early in the spring especially.

NEVER TASTED HONEY.

We took a little girl of ten years of age from the New York Juvenile Asylum, to raise. She had never seen nor tasted honey before coming here.

WHY BEES DON'T PAY.

One reason some do not make bees pay, they have so much work on hand just when bees are needing care that the golden opportunity passes by, and the bees are not made strong enough in time for the honey-harvest. Mr. Muth's article in the *American Bee Journal* on that subject hits the nail on the head, and should be read by every one keeping bees. I believe that to be one of the greatest reasons, if not *the* greatest reason, we do not secure more honey each season. If the bees are strong in numbers, and have plenty of honey in the hive, and the hive is contracted so that the brood can be kept warm, such colonies need no feeding nor nursing; and in this locality they should be set out of the cellar by April 1. But if the colony is weak, or short of stores, unless the bees have extra care, their chances for gathering honey in paying quantities, even in good years, are slim. Some practice drawing brood and honey from strong stocks to build up the weak, but I think that does not pay, neither would I unite two weak ones unless one were queenless. I should prefer to unite three or four, or else build up the weak ones; as two weak colonies, both having a queen, do not seem to be much if any stronger after a few days than before they were united. I know of nothing that a woman can work at and make pay better than to take those weak colonies under her wing and nurse them into strong ones by the time the honey-harvest comes. Men-folks say weak colonies don't pay to fuss with—at least, some in their writings say so; but I think it does pay. They should know how to do it aright, as it is death to weak colonies to be handled in unsuitable weather, and to be improperly managed.

Women as bee-keepers should plan to have all house-cleaning and sewing done up, even before time to work with bees in the spring, so that the spring care may not be neglected, as well as to have all surplus receptacles ready that will be needed, and hives ready; for, very often, other work we do not think of will sandwich itself in; and we find, with the care of our own housework, the extra care of the bees is too much; and as it is with the housework which no woman likes to neglect, nor ought to neglect, so the bees are neglected in the spring, which takes away the profit of the year.

OFF YEARS FOR HONEY.

When we are convinced that there is to be a failure we do our painting and repairing of house, barns, vehicles, etc., so as to have as little of such work to do good years as possible.

Though it has often been mentioned in our bee journals and books, that it is the strong vigorous colonies that give the most honey, yet we are prone to forget that we can not have vigorous colonies unless we have vigorous queens. Last June, when bees were gathering honey, I could remember in almost every case where the colonies were working nicely in sections, that they had reared a young queen the year before; and the colonies with old or failing queens did but little in sections.

HONEY-DEW ON HOUSE-PLANTS.

I noticed on my house-plants this fall a sweet sticky substance that tasted like honey. I suppose it was honey-dew. The window where the plants were was spattered with the sweet substance. I washed it off then, and noticed, underneath some of the leaves, a little red cocoon about as large as the head of a pin; but I saw no living insect. Last week I again noticed that some of the leaves on my oleander-tree were a little sticky, and a few of those little red cocoons, I should think they were, under the leaves.

BEE-FEEDERS.

Last fall, when we fed up some colonies for winter, we tried several feeders, and none gave better satisfaction than cheap tin milk-pans. If one buys quite a number they can be bought very cheap; and then we are sure of no loss of the syrup. We had cotton cloths over the top of the pans, and we filled them full and set them on top of the frames and covered the rest of the frames up, except large entrances for the bees to go above; and in one night they would take down two quarts or more, and worked vigorously until all was gone. We had some old wooden feeders we thought were glued and propolized so tight they would not leak; but if filled above, where tried, we found them leaking in the hive; and one that stood outdoors in the rain several days, out of which we had to pour the water, when put into the hive they let a gallon of rich syrup run out, and caused bad robbing of that colony the next day; indeed, it nearly ruined the colony, as the bees came in and took all the honey they had in the hive before we noticed the robbing was so serious. I mention the above fact to warn others to be careful of wooden or leaky feeders. This spring we intend to try large deep pie-tins, just shoved under the brood-frames, as we shall have to feed some. As our colonies are all set up an inch higher than in summer, we can take down a side board and shove the pie-tin under, first laying in the pie-tin a cotton cloth to make footholds for bees to walk out and in. A large pie-tin will hold from two-thirds of a quart to a full quart, and can be bought for three cents each, and will last a lifetime.

Roseville, Ill. MRS. L. C. AXTELL.

[Your suggestion in regard to why queens are destroyed after being clipped are, some of them, new to me; but I think you are no doubt right, my good friend.—I am glad to see that you agree so nearly with Dr. Miller and others in this matter of uniting weak colonies in the spring. A weak colony that is making progress, and is pretty surely building up, should be let alone. Two queens (in a very little time at least), will produce more brood than one queen; and if they are doubled up, one queen must take the place of two.—I wish to emphasize the danger pointed out, of opening and spreading the brood in chilly weather. It is like taking delicate plants from the greenhouse and putting them out into the frosty air.—Yes, the bee-keeper should plan certain kinds of work to be done when the honey does not happen to come.—Probably Prof. Cook can tell you the cause of the honey-dew on your house-plants, from the description you give.—Yes, I know that a tin pan can be made to answer the purpose of an expensive feeder; and this is the point I had in view when we made the machinery for making our bread-pan feeder. It is some trouble to fuss with cloths, etc. One day I found the women-folks washing out a lot of cloths that had been used over the tin-pan feeders. I soon figured up that the labor of washing them was more than the cloth would cost in the first place. Of course, where one has nothing else to do this might not be so bad; but we should be careful about letting hired help do work that costs more than it comes to. If you put your pie-plate feeders under the frames, there is a way to manage without being annoyed by the cloths at all. Have your pie-tins made just as large as the bottom of the hive; then have the sides reach high enough so that, when filled with syrup, the lower part of the frames will dip into it. A bee will never drown in such a tin pan as this, and you can fill it up by pouring the syrup on top of the frames, so as to run down between them. You want to have the lowest side of your tin in sight, however, so as not to get so much syrup in as to run it over. We have used such feeders very successfully; but it is a little trouble to get them out of the hive when you are through with them, unless your hive has a movable bottom-board. In that case, an assistant can lift the hive while you take out the feeders.]

HONEY FOR EXHIBITION PURPOSES.

A STANDARD NEEDED.

Mr. Root:—At the convention in Albany, the desirability of a standard of comparison in awarding premiums on bees at fairs and expositions was touched upon. It is a good idea, and I have long thought that a similar standard, or scale of points, should be furnished the judges of honey at such exhibitions. Better justice would be done exhibitors, awards being many times made without intelligent inspection. That is to say, they are made (with the best of intentions on the part of judges) in an off-hand manner. A case in point occurred at a State fair. After an award had been made upon a specimen of comb honey, some of the other exhibitors decided to examine it, when it was found that the case contained a few sections of white honey while the remainder was dark and inferior. The case was closed, and nothing, so far as I am aware, was ever said; but certainly the superficial examination of the judge resulted in injustice to exhibitors of better honey. If the idea should meet with approval it is perhaps not too late to induce officials to put it into the premium lists of fairs and expositions to take place during the coming summer and fall. Brought thus to the notice of bee-keepers it would have an educational value, the effect of which would appear in the better grading of honey for market. I submit the following scale for amendments:

HONEY— { Color, 5.
Body, 5.
Flavor, 5..............15.
COMB— { Straightness, 5.
Color of capping, 5.
Completeness of capping, 5...15
Uniformity.........................10
Style 10
POSSIBLE....................50

By "uniformity" is meant the closeness of resemblance in the sections composing the specimen. "Style" includes the attractiveness of section and case, also absence of propolis.

RECIPE FOR CANNING PUMPKIN, FOR MR. CHALON FOWLS.

Stew and sift the pumpkin, as for immediate use. Add sugar, ginger, and cinnamon, to taste. Return to the stove and add water if too dry. It should be somewhat soft to settle down in the can without air-bubbles, and the water can be evaporated when wanted for use. When boiling hot, pack solid in air-tight cans, and it will keep well.

HOW TO KEEP MOLD FROM CANNED FRUIT.

Perhaps it will not be amiss to make further comment on canning fruit. I have been very fortunate in exhibiting canned fruit at fairs, where many make inquiry as to my method. I very seldom have mold on my fruit, while many with whom I have talked regard it as unavoidable. Mold is a plant. When it is found on canned fruit its germs were either in the can when the fruit was put in or they got in afterward. If the can was air-tight, which can be ascertained on opening it, the mold spores could not have gotten in, and must, therefore, have been in the can when the fruit was put in. The majority of us use the Mason can with porcelain-lined top. They are musty when new from their straw packing, and, when emptied of fruit and stored upon the pantry shelf, there is abundant chance for them to become thickly sown with mold spores floating about in the atmosphere. It is almost impossible to thoroughly clean the tops and behind the porcelain lining. Mold flourishes where it can not be dislodged with ordinary scalding. However, hot strong borax water will destroy the germinating power of the spores, so I *boil* the tops and scald the cans in it the last thing before the fruit is put in. I shall use, hereafter, the Woodbury can, with glass top, made at Woodbury, New Jersey. EMILY E. WEST.

Flint, Mich., Mar. 12.

OUR QUESTION-BOX,

With Replies from our best Authorities on Bees.

QUESTION 183. *Where I live we don't usually have settled weather till well along in April. Sometimes my bees get uneasy early in March. If a warm day comes about that time, would you set out the uneasy ones and let them stay out, or would you put them back after a flight, or would you let them tough it through in the cellar?*

We would not put them back at any time.
Illinois. N. W. DADANT & SON.

If very restless, set them out; then set them in. If not very restless, leave them in until spring.
California. S. R. WILKIN.

"Tough it through in the cellar," but give plenty of ventilation and a drink. They get too dry.
Illinois. N. W. C. MRS. L. HARRISON.

I would take them out if the weather were warm, and let them stay out, unless the weather should turn cold again.
Louisiana. E. C. P. L. VIALLON.

I would let them "tough it" through in the cellar, and not set them out until outside bees were gathering pollen.
Michigan. S. W. JAMES HEDDON.

I would not set them back, and it would be a bad case if I set them out much before the usual time.
New York. C. P. H. ELWOOD.

Set out the uneasy ones, and give them protection with an outer case, and pack with chaff, fine-cut straw, or hay, or an equivalent.
Ohio. N. W. A. B. MASON.

It might pay in some instances to get the noisy ones away from the rest, and sometimes a flight will make them more quiet for a while. In such instances it will pay to take them out for a fly, and return. Early in March would be too early to leave them out, here.
Wisconsin. S. W. S. I. FREEBORN.

I think I would try to cool them off somehow, and let them remain until after the next cold spell; that is, for this latitude.
Wisconsin. S. W. E. FRANCE.

Give them water, and leave them in the cellar if they are healthy. But if they have diarrhea, setting them out for a flight, and returning them, might give them relief.
Vermont. N. W. A. E. MANUM.

Sometimes, and sometimes. If they were daubing things up I should incline to set them out for a flight, and put them back again. If they were tidy I think I should make them stay where they were, somehow or other.
Ohio. N. W. E. E. HASTY.

I don't feel entirely sure about it, but I think I'd let them tough it through. Last spring mine got that way, and I made a fire, heated the cellar, then opened every thing wide at night, and by morning they were quieted down.
Illinois. N. C. C. MILLER.

In my climate, let them "tough it through in the cellar." There is nothing gained by toting out and back again. If it is really necessary to put them out I would let them "tough it" outdoors.
New York. E. RAMBLER.

If I could take the uneasy ones out without disturbing the rest, I would give them a fly and return them. Usually this can not be done, so it is best to let them take their chances in the cellar.
Illinois. N. C. J. A. GREEN.

If I could not quiet them by cooling off the cellar—opening up cool nights—I would take the uneasy ones out and return them after a good flight. I do not believe this wise or necessary if we are cautious in our management.
Michigan. C. A. J. COOK.

If the above party would give his location, his question could be answered more intelligently. It appears to me, that, if I were a cellar winterer, I would try to quiet my bees in some manner until it was time to set them out for good. A saturated sponge on the entrance or on top of the frames answers the purpose sometimes.
Ohio. S. W. C. F. MUTH.

After trying all the plans yet devised for wintering bees in safety, my idea is this: Put the bees in the cellar early; keep the temperature at from 43° to 45° while they are in the cellar, and leave them undisturbed till you are ready to set them out for good—say when the pollen from soft maple and elm is being gathered by bees left on their summer stands.
New York. C. G. M. DOOLITTLE.

If the bees become uneasy in the cellar, and a bad condition is likely to result from it, they may be benefited by setting out on a warm day for a flight. But unless the weather *is* warm they will be damaged instead of benefited. Upon the whole the chances are about as good to leave them undisturbed until the weather is warm enough to set them out and leave them. If set out early, put back again, *especially if light.*
Ohio. N. W. H. R. BOARDMAN.

[Well, friends, I am a little glad to notice that you do not recommend very strongly carrying bees out and putting them back again, and I believe I agree with you. In fact, I think I would not take them out and put them back, even if it did no good. And, by the way, I still think that, for localities like ours, I would not have any cellar or any out or in about it. When Ernest brings his bees out of his cellar, however, I may have more faith, for the past winter has been a trying one.]

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

MASTER LELAND IVES ROOT,

CARE OF GRANDFATHER AMOS IVES ROOT,

MEDINA, MEDINA CO., O.

My dear Leland Ives:—Unless you have an imagination beyond the ordinary, you can not imagine my delight at hearing from you. I am especially gratified that you have chosen for your stopping-place the home of my very dear friends, Mr. and Mrs. E. R. Root. As you become better acquainted with them I am sure you will like them. Demure as Mr. E. R. no doubt appears to you now, when he becomes better acquainted that little stiffness of manner toward you will disappear, and I think you and he will be very fast friends. Being so very nearly the same age, it is not strange that a warm intimacy should exist between him and me, and our mutual friendship for you will bind us still closer together.

Please give my love and best wishes to your host and hostess, also to your grandmother and grandfather, also to the circle of uncles and aunts. Yours as of old,

C. C. MILLER.

P. S.—Do be careful of your health, my dear fellow, and take particular care to wrap up well when you go out. Don't go in the mud without your rubbers. Have you seen A. I.'s windmill?

A BILL BEFORE THE MICHIGAN LEGISLATURE TO MAKE THE SPRAYING OF FRUIT WHILE IN BLOOM A MISDEMEANOR.

Mr. Root:—Please announce as early as possible in your paper, that there is a bill before the Michigan Legislature, which, if enacted, makes spraying fruit while in blossom a misdemeanor. There is some opposition on the ground of justice to fruit-men. Yet our State Horticultural Society and a second large association, the "Grand River Valley Association," have unanimously resolved urging the passage of the bill. Please urge all fruit-men to petition their senator, and the State legislatures generally, to vote for and pass the bill. The petitions should come from fruit-men. They are interested in preserving the bees, as well as are the bee-men. All well-informed fruit-men believe this fully.

A. J. COOK.

Agricultural College, Mich., March 27.

[We are exceedingly glad to see you moving along in this matter, especially as the State of Illinois has already got the matter well in hand. See page 326.]

HOW TO TELL ADULTERATED WAX.

What is the best way to tell adulterated beeswax, and in what way does grease or paraffine injure wax? J. H. A.

Andes, N. Y., Feb. 10.

[Friend A., we detect adulteration by the smell, and by chewing the wax. Beeswax and tallow will make very fair chewing-gum. But wax alone will crumble all to bits, and can not be chewed—at least very long. The addition of paraffine has somewhat the same effect; and even a very little paraffine makes the wax melt at a much lower temperature, so that it is entirely unfit for foundation. If the sample in question should, with very mild heat, become soft and mushy, you may suspect paraffine. Beeswax, however, is tough and leathery, and easily rolled at a temperature where paraffine would have no toughness at all.]

ILLINOIS STATE BEE-KEEPERS' ASSOCIATION.

The Illinois State Bee-Keepers' Association was organized on the 26th day of February, 1891, at Springfield. It officers elected were:

President, P. J. England, Fancy Prairie.

Vice-presidents, Mrs. L. Harrison, Peoria; C. P. Dadant, Hamilton; W. T. F. Petty, Pittsfield; Hon. J. M. Hambaugh, Spring; Dr. C. C. Miller, Marengo.

Secretary, Jas. A. Stone, Bradfordton.

Treasurer, A. N. Draper, Upper Alton.

A constitution was adopted, fixing Springfield as its principal place of business. Thos. G. Newman, of the *American Bee Journal*, was made its first honorary member.

Its executive committee are the president, secretary, and treasurer. The meeting at which the organization was formed was one of enthusiasm, and all seemed to feel that a day had been profitably spent. Adjourned at a late hour, to meet at the call of the executive committee. JAS. A. STONE.

Bradfordton, Ill., March 29.

WHICH IS THE CHEAPER—GRANULATED OR COFFEE A SUGAR?

I had occasion to buy a barrel of sugar for feeding bees yesterday, and intended to buy A sugar. The wholesaler asked for what purpose I wanted it, and, after saying for feeding bees, he said I wanted granulated, as there was more sugar for the money. Their sales of sugar, as he showed me by their books, run 5 barrels of granulated to 1 of all other kinds. Granulated is 6 per cent water, A 19 per cent. They had yesterday morning 27 carloads of sugar. I write this as I was intending to try A sugar as you sometimes use it. It is an easy matter to figure out the cost of *sweet* by using the percentage given. F. A. SALISBURY.

Syracuse, N. Y., April 2.

BEES ALL RIGHT IN THE CELLAR.

Bees are quiet yet, and seem to be all right in the cellar. Clover seems to be in good condition yet. Prospects are good for this season. I am not discouraged yet. I am building a shop 16x24, two stories, in hopes of a good crop this year. N. STAININGER.

Tipton, Iowa, March 26.

CATCHING FISH THAT WEIGH OVER 100 LBS., WITH A HOOK AND LINE.

Inclosed find a tarpon scale, taken from a tarpon caught by John D. Wattles, of Philadelphia, publisher of the *Sunday-School Times*. This fish was taken with a rod and reel, measured 6 ft. 6 inches, and weighed 130 lbs. Another was caught to-day by Leslie Pell Clark, weighing 110 lbs. The silver on scale is all that shows on the fish, giving it the name (by some) of Silver King. Bees are booming.

Sarasota, Fla., March 21. S. C. CORWIN.

DRAINING THE CARP-POND.

Tell Huber he should have been here in November when we drained our carp-pond, to help to take out the thousands of carp, from two inches in length to 20 inches. We now have them in one supply-tank, 10x10 ft., by 10 ft. high;

and some of the large fish we have in a low tank, so we can get them to eat. We had a nice one for Christmas dinner. G. J. KLEIN.

Conrad Grove, Ia., Jan. 24.

SPECIAL DEPARTMENT FOR A. I. ROOT, AND HIS FRIENDS WHO LOVE TO RAISE CROPS.

COMMON DRAIN TILE FOR CARRYING EXHAUST STEAM IN HOT-BEDS.

When I first thought of this I greatly feared that the dampness and wet of the steam would keep the hot-bed not only warm, but wet and soggy; that is, where steam is run through tile of only one-foot lengths, every joint permits the steam to get out more or less; but to my surprise and joy I found it just the other way. The ground dries over the tile a good deal as it does over a hot-air flue. Where the tile runs under a pathway between the beds, the ground is dry, even now while it is raining. The exhaust steam warms perfectly a string of beds 6 feet wide and 250 feet long, and the waste steam goes out at each end—enough in quantity to do considerable more work if needed. Strawberry-plants are now in bloom; corn and beans are doing nicely, even though we have had the most severe weather of the winter within the past two weeks. There has been no lack of bottom heat; but once or twice, when we omitted to ventilate promptly, the whole bed got so hot that some of the plants were injured slightly.

A NEW WAY OF VENTILATING HOT-BEDS AND COLD-FRAMES.

Now, it may not be new to the rest of you, but it is new to me. Instead of pulling the sash off, or even tilting them, simply spread them two inches apart. When placed thus, there is nothing that can be injured by the heat of the sun, neither is there any danger from quite a freeze; and in transplanting it gives the best results of any I have tried—that is, unless the sun is very hot. If we strip the sash clear off, the sun and wind would often dry up the ground too rapidly, and the plants look shriveled. A drying wind is rather worse than the sun. Now, by spreading the sash as I have mentioned, the wind is practically excluded, and yet the plants have a free circulation of air—almost equal to outdoors. But for some reason which I do not quite understand, these separated sashes almost always have more or less dew on the under side of the glass. Sometimes the quantity is so great that it falls in drops on the plants underneath, and with this amount of dampness they do just boom. To-day is the last day of March, and we are having a veritable April shower.

TREE TOMATOES.

As considerable has been said about these in our catalogues and some of the papers, we have thought best to give an extract from a little circular, as follows:

HOW TO GROW THE WM. MANSFIELD TREE TOMATO.

Get some rich old earth for boxes in your house, hot-bed, or greenhouse; sow seed, cover lightly, wet down well every day, keep warm with all the sun possible. When up ten days, transplant to other boxes, six inches apart, in dirt not less than four inches deep. Keep them wet, give all light and sun you can; and by the time it is safe to set them in the ground outdoors they should stand from twelve to twenty-four inches in height, with bodies one-half inch through.

Now for the ground, and how to prepare it. First select a spot as near your water as possible. Let your rows run east and west. Throw out dirt two spades deep, then put in three or four inches of night soil, if you can get it. If not, use hen manure and wood ashes, equal parts, or some other strong manure in the bottom of trench. Then fill up trench with the best dirt you can get, well mixed with old rotten stable manure; there must no strong, new, raw manure come in contact with the roots nor bark above the ground, as it will destroy them; but from bottom of the trench it is safe, and will throw up strength for the whole season. Now your ground is ready. Set out your plants (without disturbing any of the dirt around the roots) about eighteen inches apart; have the dirt in your trench a little lower than the sides. Have a strong stake for each plant, or a trellis, and tie them to it as fast as you set them. Water immediately, and ever after. Run a trough or small ditch from your pump to your plants; and every day, unless it rains, send a stream of water into the trench where your trees are set. Hard water, soft water, cold or warm water, are all right if they only have enough, either from the clouds or pump about once every day. As your plants begin to grow, just above each leaf will start a sucker. Let the top of plant, and only one or two of the best top branches grow so that you have not over two or three stems to run up. Now, by close observation you will see always that the buds for blossom show themselves on the tops of the trees, and a few inches below them; and just above each leaf the sucker starts. Nip off every one of these just as fast as they appear; also, as the lower leaves get brown and old, pick them off. Train the fruit as it grows, to the sun. Tie often and well. Let no useless wood grow. Give all the sun possible, and water, water, water—then you will be able to pick ripe fruit of the finest quality from about the Fourth of July until frost comes.

Johnsons Creek, Wis. WM. MANSFIELD.

The writer of the above has been, so he says, working for a new strain of tomatoes, to be grown like trees, for the last twenty years. During 1890 he said he had trees eleven feet high, bearing tomatoes weighing 2 lbs. 6 ounces. There is one thing in favor of these tree tomatoes, or tomatoes trained on stakes: The hens do not touch them, and they never get soiled or muddy. During the past season it was quite a task to wash and wipe perfectly clean our choice Ignotums. It would probably be rather late now to sow the seed, if you want *early* tomatoes. Very likely our friend Mansfield has plants to sell, for those who wish to try them the present season. We do not see any thing about the price of seed or plants in the little pamphlet from which the above was taken. I think the *Rural New-Yorker* stated recently that *any* tomato would make a tree tomato if tied to a pole, and trained and directed as above. During a dry season I am inclined to think the directions given—"water, water, water," a great help, provided we have the sunshine to go with it.

HOW BOOKS HELP.

I received the books I sent for, and I must say it would have been dollars to me if I had known of the A B C of strawberry culture. We bought a small farm near the city of Alpena, two years ago. There was something over an acre of strawberries on the farm. They did fairly well; but not knowing any thing about the care of strawberries we did not manage right. My husband is a sawmill man, and I do the farming with the help of a boy 18 years old. We are two miles from the city. I send the berries in three times a day through the busiest of the picking.

MRS. A. E. MONTAGUE.

Alpena, Mich., April 2.

TERRY'S STRAWBERRY CULTURE.

The strawberry book is a jewel. Every farmer should have a copy, especially if he has children. Friend Terry should live in California, where he can have strawberries at least seven months in the year, and some, I hear, do better than that. One great secret of his success is his thorough cultivation, especially after every rain, which causes the ground to retain moisture. Many farmers east make a mistake in thinking no need of cultivation unless there are weeds to kill. Here in this long season of dry weather we easily see the benefits of cultivation, which is, practically, mulching the ground with fine earth for retaining the moisture. The harder the rain the harder the ground is packed; and the quicker it dries out, comparatively, unless cultivated.

Lakeside, Cal., Mar. 23. F. C. Crowell.

OUR HOMES.

Lord, when saw we thee a hungered, and fed thee? or thirsty, and gave thee drink? When saw we thee a stranger, and took thee in? or naked, and clothed thee? Or when saw we thee sick, or in prison, and came unto thee?—Matt. 25:37–39.

I had it in mind to write something this time in regard to the happy surprises that are continually falling to the lot of the faithful, earnest Christian; and then the next thing was, to find a text which embodied the thought. When I found it in my well-marked Bible I saw the very text I wanted was already so plainly outlined with a pencil that it must have been used before. Never mind; I think it is just what I want to-day.

For several years before I accepted Christianity, one of the uppermost thoughts in my mind (perhaps I might say *the* uppermost) was, that the world was not giving me due credit. I would say to myself, and even to my friends, "Here, I have invented this, that, and the other, and here it is described in this and that bee-journal, and no credit given me whatever." Again, I would dwell on the fact of what I had done for different people, and not a word of thanks, and no expression of gratitude. Dear friends, did you ever get into this attitude of mind? I might go on giving you quite a list of the ways in which I used to think I was not getting my just dues, or did not have a fair chance; but the subject is so painful to me, and, in fact, I feel so much ashamed to think that I ever cherished such ungratefulness and such preposterous egotism in my heart, that I would fain let it drop. I remember once of a distinguished lecturer from some of the great cities, who visited our town. Some friend brought him into our establishment, and introduced him to me. Now, here was an excellent opportunity for me to *hear* a great man talk. But I remember quite vividly how I occupied the whole fifteen or twenty minutes he stayed at our establishment, by telling him what wonderful things *I* had done. In fact, I hardly gave the good man an opportunity to say any thing himself at all, even had he been so disposed. Very likely some of you will say, "Why, my good friend Root, are you quite sure you have entirely gotten over that trait of character even now?" I know very well, my friends, I have not. It is not an easy thing for anybody to get *entirely* out of the ruts and failings that have clung to them for a good many years. The grace of God has helped me, however, so much in this respect that I feel as if I wanted to tell you something about it.

Before I became a Christian, if anybody trod on my toes, or trespassed upon my rights, I was ready to fight, or to go to law, without a moment's warning; and the saddest part of it was, that a good many times I imagined they trod on my toes purposely, or trespassed on my rights purposely, when they had no such thoughts or intention. By the way, do you know of any thing much sadder than to have a friend who laments that everybody is all the while trying to steal what belongs to him? It does not matter whether it is the corn in his crib, or the eggs his hens have laid, or even the thoughts of his brain; if he gets into the idea that he has got to fight continually for his just dues all through life, the spectacle is a sad one. A great part of the exhortations of God's holy word are exactly to the contrary. How many texts do you suppose I could quote right along on this line? "Cast thy bread upon the waters;" "Give, and it shall be given unto you;" "He that findeth his life shall lose it: and he that loseth his life for my sake shall find it;" "Thy Father which seeth in secret shall reward thee openly;" "Do good and lend, hoping for nothing again."

Before my conversion I was greatly disturbed if people talked about me, especially if they said any thing that was not true, and then I thought it incumbent on me to follow up any such report, and go to the bottom of the thing. When any thing got into the papers reflecting on me, I was ready to fight the editor, and prosecute the man who told the untruth. I remember when a rival in business put in something abusive, and I could hardly sleep the whole night after. Now, please do not think I am bragging when I tell you of how I was helped out of all this "miry clay." Remember, *I* did not do it of *myself*, therefore the credit or the praise can not in any sense belong to me; but to *Christ Jesus* shall we ascribe all the glory and praise. After my conversion I *forgot* about self; in fact, I did not *care* about self. Why should I? The promises of the Bible, without number, exhorted to the contrary. He that loseth his life shall find it. I *did* lose my former life, and I *did* find the new; and this finding of the new life constituted "the happy surprises" that I wish to tell you about to-day.

In a great measure, the *desire* to fight back was gone; and, in real truth, it was *not* very hard to *love* my enemies and to do *good* to them that hated me. I did not find it very hard to do *good* and *lend*, hoping for nothing again, for I was trusting in Christ Jesus, and I fully believed he would take care of the outcome and the result. Many of you who have read Gleanings *know* how it turned out. "When a man's ways please the Lord, he maketh even his enemies to be at peace with him," and it happened *just* so. Many of the pleasant surprises I have had come in the way of kind words from those who have formerly been at enmity toward me. People said I was queer and odd and eccentric, and that they did not understand me at first; in fact, I was not *trying* to have them understand me. I was trying to have them understand *Christ Jesus* and the holy Scriptures. A few days ago our good friend Dr. Tinker paid us a visit. He said to me, "Bro. Root, you may remember that I have not always felt as friendly toward you as I do now. I did not understand you. Since I have become acquainted, and know you better, it makes a vast difference; and there are a good many who do not understand you, even *now*. If they could come here and go all around, and see you when you are at work, they would change their minds, just as I have done."

In that new life, instead of being afraid of being put in the papers, I did not care whether I was put in the papers or not. Now, please do not misunderstand me. Do not imagine that I was one of the "don't care" sort. My *care* was, however, that I should in no way dishonor the Master. I was in great fear every day of my life that I might not be *truthful* and *honest*, and *pure* in *heart*. But after I had worked and prayed through these temptations to be untruthful, or dishonest and greedy, I did not care for the result, for that, in fact, rested with Him whom even the *winds* and *waves* obeyed. Why should *I* trouble myself? Before conversion I was afraid that the great outside world might point out some things about me that I would not have anybody know for the world; but *after* conversion I had nothing to conceal. When there were rumors that something in my past life might get into the papers, I decided, as some of you may remember, to put it in print *myself*, and then I should never be afraid that it might come up at any future time. About this time I was in pursuit of information of a certain character, and was directed to a certain place. My informant added, also, "You had better not be *seen* going there, Mr. Root; for if you are, you may get 'talked about,' and you know *you* could never stand that." And then the bystanders had a big laugh, as they supposed, at my expense. There was a moral to it, however, for every one of them recognized that *all fear* in that direction was gone. My attitude was then, and I hope and pray is still, that, when the truth will do harm, let harm *come*. We read in the 112th Psalm, "He shall not be afraid of evil tidings; his heart is fixed, trusting in the Lord; his heart is established, he shall not be afraid." And then in the 91st Psalm we read: "He shall give his angels charge over thee, to keep thee in all thy ways. They shall bear thee up in their hands, lest thou dash thy foot against a stone."

One of the great hindrances to these happy surprises I have been telling you of is the disposition, not only to lose faith in God, but to lose faith in your fellow-men. And, by the way, there is something really wonderful in the way this temptation to be uncharitable will follow one, and continue to hang to him, even after he has had experience again and again that should teach him better. I have been between fifteen and twenty years battling against this besetting sin of mine. If anybody should ever have learned by abundant experience to look out for danger and delusion right here, I am that one. Let me give you an experience of yesterday:

Circumstances seemed to indicate that a certain individual was purposely planning hindrances in our way. I watched him narrowly, and finally I had proof of it (or at least I supposed I had) in plain black and white. There could be no mistake about it. I had his own handwriting in my fingers. It first gave me a feeling of pain that he should, for any reason, real or imaginary, be so perverse and wicked. Then I began planning unconsciously what I should do to stop it. It disturbed me so I could hardly talk or eat my supper, yet I decided that it was not worth while to trouble my wife about it. Then I remembered the many grievous mistakes I had made just in this line, and I finally submitted it to my wife's better judgment. She said at once, "I am sure you are mistaken."

"But, my dear wife, how *can* there be a mistake? Oh, how I wish there *were* some chance for him! But right here are the *facts*."

"I can not help it. I am sure this friend of ours has not deliberately and purposely done this thing."

I felt a little relieved; but the facts were so straight and clear, I placed the matter before another good friend. This friend said just as Mrs. R. did.

"It can not be, Mr. Root. I do not know what it means, and it is hard to explain; but there is certainly a reason for it that we do not see."

I had decided, therefore, out of respect to these two good friends of mine, that I would ask the one who seemed to be going wrong, for an explanation. I decided, too, to put it very mildly, and to assume, for the time being, that no wrong had been premeditated. What do you think the result was? Why, it was just the old, old story—nothing was wrong at all; or, perhaps I should say, nobody was wrong at all, except my own self, and the bad, uncharitable condition of my own heart. In the piece of handwriting I had looked at so suspiciously there were two little characters I had overlooked, and these made it all plain and simple. Oh how thankful I felt that I had listened to the advice of these two friends, whose minds were in no way biased, as mine was for the time being by my old foe and old enemy. Now, then: Jesus knew all about this. He knew exactly where we should be likely to be tripped and entrapped; therefore he said, as a preventive—as a safeguard—perhaps I might say as a note of warning, "Love ye your enemies; do good to them that hate you," etc., knowing *beforehand* that we should be prone to look for enemies where none exist, and that we should be very likely to imagine people hated us when no such *hatred* existed; so you see that, if we listen to these words of Scripture, we shall, *without knowing it*, escape Satan's snares; and in this way we shall meet with the happy surprises that I have been telling you of. We shall find warm friends where we had been looking for foes, and we shall discover good loving hearts where Satan whispered only envy and enmity existed.

In our issue for March 15, page 226, I published a letter from friend Braley. I did it with a feeling that there had, perhaps, been too many kind words in GLEANINGS, and not enough of the opposite sort. I feared the impression was going out among my good friends that the bee-keeping world were *all* pleased with our establishment, whereas that is not true. There are quite a few who do not agree with the majority, and justice and *truth* demand that they have a hearing. I did not feel unkindly toward friend B., but I felt sorry to know that he did not understand me better, so I replied to him in a footnote. By the way, may I suggest that editors, as a rule, *are* afraid of adverse criticism? We put in plenty of notices in regard to the *value* of our journals, and how well they pay as *advertising* mediums; but when somebody writes a complaining letter, and says he "never got a *cent*" in response to his advertisement, it is a little against human nature to publish it. Now, it seems to me that our patrons have a right to *all* the information we can give in the matter. If we wish to be *honest* and *square* we should give *both* sides; therefore *I* rather enjoy giving *both* sides. Why, bless you, dear friends, it never hurts one nor hurts his business to be *honest*. See the promise in Isaiah 54: 17:

> No weapon that is formed against thee shall prosper; and every tongue that shall rise against thee in judgment thou shalt condemn. This is the heritage of the servants of the Lord, and their righteousness is of me, saith the Lord.

But, please believe me, I had not the *remotest thought*, when I published friend Braley's criticism, that it would be the means of bringing me the kindest expressions of abiding friendship, high esteem and gratitude, that I ever got in my life. Had I been *seeking* praise I could not have invented a better scheme than the one I innocently and unconsciously took, of publishing that letter. In fact, it brought a *series* of "happy surprises," and quite a few from good friends whom I longed to hear from, but whom we could not get to write. I did not feel hurt nor troubled because he accused me of being a hypocrite, for I am greatly afraid that hypocrisy *does* get into my composition now and then; but I certainly was not bright enough to recognize that nothing in this world brings to light one's friends like unjust persecution; and I suspect that herein is one of the truths at the bottom of one of my old favorite texts: "Blessed are ye when men shall persecute you and revile you, and speak all manner of evil against you falsely for my sake." Especially if the one who is persecuted unjustly takes it quietly and pleasantly, and does not say a word back, nor retaliate in any way. May be I am letting out a great secret here; in fact, I rather *hope* I am; for if I can make plain to you the wonderful secrets embodied in the Bible texts and promises—if I can, in short, point you to the *Lamb of God*, who, when *he* was "reviled, reviled not again," why, it is just the work I *love* to do rather than any thing else God has ever called me to in this whole wide world. And now let me finish by giving you some extracts from kind letters that have come since the above was published:

Friend Root:—I have been thinking of writing to you for a long time, as I have good evidence that you still retain recollections of your brief visit with me, and might be interested in knowing about my welfare; but many cares have prevented, and might still do so but for some things which appear in the March 15th issue of GLEANINGS. They "sort o' riled me," and I will refer to them later. Providence has, since my mother's death, granted me a boon which does not fall to the lot of very many, to judge from appearences—a good wife, who is, in the true sense of the word, a helpmeet. Home is, once more, more than "a place to stay;" and I am sure that, if you conclude to come to California again, you will find a happy spot when you visit us. I have about as many bees as formerly, but the strawberry patch has given way to a thrifty young orange-grove, and a three-acre orchard of figs and apricots is growing finely above the house.

Now, in regard to the articles of criticism which appear in GLEANINGS. It does seem a little peculiar that some people do not use more good sound sense in arriving at conclusions; for instance Mr. Braley, who gets the shoe on the wrong foot *entirely* with his "big I." It would seem that the individual who demands that any publication shall be gotten up exactly in the line of *his* likes and dislikes (irrespective of what its other readers may require), bristles all over with egotism, or "big I"-ishness; and in writing as Mr. B. did, he shows about as much consistency as the person who goes to the butcher's shop after beef steak which he *likes*, and proceeds to abuse the proprietor for keeping *sausage*, which he does *not* like. There has been information in the last few numbers of GLEANINGS worth a dollar to *any* bee-keeper; and, for that matter, valuable to all; and if one finds something "obnoxious" occasionally, I know of no law to compel him to read it.

As to Mr. Luther's article, I am also a member of the association mentioned, and was present at the meeting Jan. 8th. I take issue with him. If Mr. L. takes his honey to market and receives a bid of 4 cents, does he consider it "dishonorable" to inform another buyer that he has such an offer, and then sell to him at 5 cents? Certainly not. When business throughout the country is run on principles as nearly parallel to the Golden Rule as is A. I. Root's, we shall be a long way nearer the millennium than at present. S. B. WOODBERRY.

Verdugo, Cal., Mar. 23.

Dear Bro. Root:—I feel it my duty to address you to-day as a Christian brother; and if we do not buoy each other up in this Christian warfare, and fly to each other's assistance, we do wrong, and I consider it a sin. God is our refuge and ever present help in trouble. I believe it; but we do like our fellowmen to understand why we so talk, why we so act. But they can not and will not, and then fling mean and small words at us. How can a Greek and Frenchman understand each other's language? How can one who is not a Christian know of the love that God has placed in his soul for Christ and his fellow-men? But to know and feel that you act and say all for Christ's sake is a great blessing in itself.

I have, as an officer in my church of 300, given my views most emphatically against all fairs, banquets, and concerts in God's house, to raise money to carry on his cause. I don't believe in it. The Holy Spirit moved me to take this stand, so very contrary to my former views, that it has called down from the members such words as to trouble me; but I can stand with Christ's aid, as I know it cometh not from the Devil, but from Him who gave his Son for us. The power of the Spirit worketh wonders; and I desire it, oh so much! Now, this sympathetic bond is why I write to you. After reading Mr. Braley's letter, page 226, I feel that you must want some sympathy. It relieves me to give it. They don't understand you. Let them talk. It makes you stronger for Christ's service. It all redounds to the glory of Christ. You are a great instrument in his hand. Your Home Papers have ever been a helping hand to me in my business, in my prayer-meeting, and in my home; and I shall pray now for you and yours, that you may continue to serve Christ in your way, under the guidance of his Holy Spirit, all your days, and at last be united with Him who loves you—loves *you*—more than you ever dreamed of, and has now a place ready or prepared for you. This letter requires no answer, and is not for publication.

The last brother who writes, says the letter is not for publication; and it is quite evident to all that he had no thought of its being used in that way when it was written. I trust, however, he will pardon me when I tell him that it strikes the point I wish to illustrate, much more fully than any of the other kind letters received in answer to our good friend Braley.* Perhaps I should also apologize to our readers for permitting any thing to get into print containing such extravagant praise of myself as the last few words. But it is these few words that bring out the wonderful truth in the text I have quoted: "Blessed are ye when men shall revile you and persecute you," etc. Now, please note, the blessing is promised when this persecution is *unjust* or *untrue*, and when it comes *because* of Christ Jesus, or for *his* sake. If you are guilty of some wrong act, and you are persecuted and reviled because of that, no blessing is promised. It is only when we are entirely innocent. And, now, please note again, the greater the injustice you suffer, the *greater* will be the blessing. Many of you, probably, will refuse to believe this; but see how it has been verified in my own case, in the promise before us. Friend Braley said some spiteful things about me, because of the Home Papers, because I, in my poor way, *tried* to hold up Christ Jesus as an example for the world. Did it hurt me? or did anybody think the less of me? Quite the contrary. It stirred up friends from the Atlantic to the Pacific, and induced many to write encouraging words who probably would not have said *any thing* otherwise. Several have seemed to fear that I might be induced to drop the Home Papers, and sent in vehement protests and kind words like those I have given you. The 22d and 23d verses of the 6th chapter of Luke contain some words that have always seemed to me to be a little extravagant—at least, I have been tempted to think there might be some mistake about it. They are as follows:

> Blessed are ye when men shall hate you, and when they shall separate you from their company, and shall reproach you, and cast out your name as evil, for the Son of man's sake. Rejoice ye in that day, and leap for joy; for, behold your reward is great in heaven; for in like manner did their fathers unto the prophets.

The words I allude to are, "Rejoice ye in that day, and leap for joy." What a contrast! My friend, if you have ever lain awake nights because somebody accused you of something of which you were entirely innocent, do not do so any more. Have faith in the Bible promises. If there is any *truth* in the unkind words, then bestir yourself to make them *untrue*. If somebody has accused you of something that you never did at all, look into your own heart and see whether you ever *thought* of so doing. If you did, there is where you are to fight your enemy. Jesus said, in connection with this very thought, "But I say unto you, That ye resist not evil." Do not trouble yourself about the evil at all, and do not waste your energies in even making a reply. Turn all your thoughts, and do all your fighting, against the evil in your own heart. *Keep busy* in resisting every encroachment of the evil one, and then shall come these happy surprises that I have been telling you about to-day. Then will you feel like saying, when the dear Master sends you—yes, here in this world—more wonderful blessings than you ever thought of or dreamed of—

---

* Perhaps I may add, that the writer of this last letter has been well known to us for several years. Ernest and John have met him personally, but we were greatly astonished, all of us, to receive *such* a letter from one whom we had hardly any reason to suspect was even a professor of religion. And may I just drop a word of caution right here to our brother in regard to church fairs? Even if he is wholly in the right, would it not be well to heed the injunction, "Not by might nor by power, but by my Spirit, saith the Lord of hosts"? These things are much more easily set right by a loving and gentle hand.

Lord, when saw we thee a hungered, and fed thee? or thirsty, and gave thee drink? When saw we thee a stranger, and took thee in? or naked, and clothed thee? Or when saw we thee sick, or in prison, and came unto thee?

TOBACCO COLUMN.

CONDITIONS UNDER WHICH WE GIVE SMOKERS TO PERSONS WHO STOP USING TOBACCO.

First, the candidate must be one of those who have given up tobacco in consequence of what he has seen and read in this department. Second, he promises to pay for the smoker should he ever resume the use of tobacco in any form, after receiving the smoker. Third, he must be a subscriber to GLEANINGS. Any subscriber may, however, have smokers sent to neighbors or personal acquaintances whom he has labored with on the matter of tobacco-using, providing he give us his pledge that, if the one who receives the smoker ever uses tobacco again, he (the subscriber) will pay for the smoker. The one who receives the smoker in this case need not be a subscriber to GLEANINGS, though we greatly prefer that he be one. because we think he would be strengthened by reading the testimonials from time to time in regard to this matter. The full name and address of every one who makes the promise must be furnished for publication.

OBJECTIONABLE PICTURES IN PACKAGES OF TOBACCO.

Mr. Root:—I inclose with this two pictures given to me by men in the shop where I work. They come in papers of tobacco that are sold to anybody who wants them, old or young, and are circulated everywhere. No doubt you will find the boys, if not the girls, in your schools, are too well acquainted with them. I believe they are supposed to represent theatrical costumes, and may be inside of the law; but if so, the law needs to be changed, and I thought perhaps you might be able to start an effort in that direction.

New Jersey. B. C. W.

[Now, then, if there is any man (of course there is not a woman) who would defend the use and sale of tobacco after the point made by our good brother in the above, we should be glad to hear from him. The very fact of itself, that evil, vicious men have chosen tobacco packages as a vehicle for their infamous work, is enough to condemn it. The Christian man (or, perhaps I should say, the professors of religion) who sell tobacco, knowing that the packages contain these objectionable pictures, should hide their faces in shame if they do not give up at once and for ever this traffic. The plea that there is money in it is no excuse at all, but rather the contrary. A good friend of mine who got hold of some of these vile sheets, put them in a letter and mailed them to a grocer who advertises prominently that he makes tobacco a specialty. She asked him if he could consistently sell any class of goods that included things of an immoral tendency like these, telling him at the same time that the pictures she inclosed came out of the packages of tobacco bought at *his store*. At the present writing he has never made any reply whatever.

Bro. W., you are right about it. If these things are not against the law, the law certainly needs *mending*. Only last week a Medina Co. boy was arrested for printing and sending out obscene literature made on a little amateur press. I was told that the full penalty of his crime would be five years in the penitentiary. His father got him clear, however, by the payment of $500. This boy scattered his infamous productions among the schoolchildren. Now, if it is five years in the penitentiary for printing and disseminating vileness and obscenity, why is it that our tobacco-dealers (providing they have no conscience) are allowed to go scot free in this matter of putting out, with their tobacco, obscene pictures? The pictures are exactly the kind calculated to stir up the worst and the most dangerous passions in human nature. I know by experience the extreme harmfulness of like pictures—pictures shown me by thoughtless or vicious schoolmates, which have haunted me—or at least the memory has—through life. And even since I have become a Christian I have prayed again and again that God would wash away and obliterate the recollection that has followed me for toward forty years.

Friend W., I thank you for the confidence you place in my ability to do something in this line; and may God help us to use our privileges. If Prof. Cook, Dr. Mason, Dr. Miller, R. L. Taylor, and a host of others whose names have weight, would start a petition to make it a penalty to put this stuff in tobacco packages or anywhere else, I think there is no doubt but that we might succeed. Our excellent Postmaster-General, Mr. Wanamaker, is wide awake and in dead earnest in excluding every thing of this kind from the *mails*. Therefore the enemy is making every attempt to reach boys and young men through other avenues; and with satanic aptness and ingenuity, they have decided to put it in *packages* of *tobacco*. May God help us.

My son, Wiley H. Barbee, has quit the use of tobacco, and he thinks he is entitled to one of your smokers. If you think he is worthy of one, please send it to my address, and I will see that he gets it. DANIEL BARBEE.

Glenwood, Ia., Feb. 26.

Please send a smoker to Albert Donaldson, Courter, Miami Co., Ind. He has quit the use of tobacco. If he ever uses it again I will pay for the smoker. I have not broken my pledge yet, and never expect to. CHAS. CRANING.

Courter, Ind., Jan. 26.

Through the influence of the Tobacco Column I have concluded to quit the use of tobacco. If you will send me a smoker I will never use the weed again; but if I should fail to keep my promise, and ever use tobacco again in any form I will pay you for the smoker.

Morgan, Ky., Feb. 23. HENRY C. CLEMONS.

Inclosed find $2.00. Take enough out to pay for a Clark smoker, and the rest apply on GLEANINGS. The smoker is one I ordered sent to a man some time ago who had quit the use of tobacco; but as he has broken his pledge I shall have to pay for the smoker or break *my* pledge. E. C. EAGLESFIELD.

Berlin, Wis., Feb. 26.

GLEANINGS IN BEE CULTURE
A Journal devoted to Bees and Honey and Home Interests.

Great peace have they which love thy law, and nothing shall offend them.—Ps. 119. 165.

On account of the quantity and excellence of available matter we enlarge again to 52 pages. Be sure to read the discussions pro and con on fixed distances and wax secretion in this issue.

The advantage of having a practical bee-keeper in the halls of our legislatures is illustrated on page 326. A few such laws will have a wonderful educational influence in favor of our pursuit.

During our spare evenings we have been reading with profit and delight the "Mysteries of Bee-keeping," by Quinby. We have been charmed with the magnanimous spirit of Father Quinby.

We must really apologize for calling our friend George H. Ashby, of Albion, N. Y., George H. Ash*mead*, in our N. Y. State convention report. The former says he has been getting a great many letters directed to the latter.

Fixed frames have been and are used in England almost exclusively, among bee-keepers; and in looking over the back volumes of the *British Bee Journal* we noticed that our British cousins have tested and tried almost every thing conceivable in the line of fixed distances.

We have just had a call from Mr. R. F. Holtermann, who has recently attached himself to the bee-keepers' supply department in the firm of E. L. Goold & Co., Brantford, Ont. Mr. H. was former Secretary of the International Bee-keepers' Association. He is a bright and progressive bee-keeper, and will be a valuable addition to the Brantford firm.

One of the biggest pieces of folly is to send for bees long distances, by express. You can just as well get improved strains by getting queens by *mail*, and introducing them into your hybrid or black stocks. Haven't got any common bees? Buy some of a neighbor—that is, if you want to start in bee-keeping; get a few hives in the flat, of your nearest supply-dealer, and then get your pure Italian stock by mail, wherever you like.

Hope is the word engraven on the heart of every bee-keeper at the beginning of every season. "We are going to have a good season this year," and so preparations are made. Without hope or expectancy there would be no preparation, and consequently no honey crop. Without bees and proper appliances at the right time, a big honey-flow does not amount to much; and so it behooves us to be ready for whatever may come.

Our yellow five-banded bees were the first to be numbered among the dead in winter losses. Our apiarist says the three colonies we had of them had evidently died very early in the winter. After all, it may have only *happened* so; but still there seems to be a sort of opinion prevailing, that the darker bees are better for wintering and better for honey. The next two years will tell us more about it. A. E. Manum attributes his successful wintering largely to his leather-colored strains.

The Hubbard section-former is a good machine—the best of the kind we know of. We let the one we had in use go for an order—the only one we had, and, oh my! what a scold the girls made! They didn't like to go back to the old way of folding sections. We now have plenty in stock.

"Some patent-hive men," says a correspondent, "are like a dog with a bone that has no meat on it—ready to snarl and bite, the more especially when the bone is entirely worthless." This is a very true saying. Does some patent-hive man take offense at this? Well, he mustn't put the shoe on, if it doesn't fit. Observe that he doesn't say *all* patent hive men "are like," etc.

Mr. F. H. McPherson, of the *Canadian Bee Journal*, whose fall upon the ice was mentioned recently in Stray Straws, is still unable to resume his duties, and is at present under the medical care of an eminent physician in Toronto. The accident was more serious than was at first anticipated; but it is hoped that, with a complete rest for a time, he will soon be himself again. We extend our sympathies to Bro. Mac.

Perhaps some of my friends may accuse me of playing second horn for Mr. Elwood and Mr. Hoffman. Well, if I am, I am in good company. They are both intelligent and extensive bee-keepers, and they have no ax to grind. Outside of their general interest and the welfare of the pursuit, it matters very little to them whether their suggestions are adopted or not. E. R.

Quite by accident, this seems to be something of a topical issue. Notice the discussions, pro and con, on wax secretion, and on fixed distances. No more valuable subjects could be discussed than these. On the solution of the wax question hinges the much or little use of foundation, or the value of a surplus of empty combs. It may not be possible just at present to settle the fixed-distance question; but the discussion shows how honest and good men see things differently.

We have received scores of congratulations from friends and bee-keepers all over the country, over the advent of our Easter offering, a baby boy, Leeland Ives. To one and all we extend our hearty thanks. You will pardon us, but we want to copy a little bit from a letter from Mr. Elwood, who, after extending his congratulations, adds:

> Speaking after the manner of bee-keepers, I trust you will find that a moderate increase is not only best in securing to you the greatest amount of the honey of life, but equally good in maintaining the old stocks in the greatest vigor. P. H. Elwood.
>
> Starkville, N. Y., April 4.

DEATH OF MR. COWAN, SON-IN-LAW OF L. L. LANGSTROTH.

Dear Friend:—My son-in-law, Hugh C. Cowan, left us this Sabbath morning for the better world. His health gave way more than a year ago, and for the last few months he has been confined to the house. His disease was consumption. He died in the blessed expectation that, when absent from the body, he should be "present with the Lord."

Yours affectionately,
Dayton, O., March 22. L. L. Langstroth.

Dear friend, it is not a sad thing to die when one dies in the blessed faith, as mentioned in the above. Neither is it, in one sense, a sad thing to bid adieu to these friends—certainly not when we think of what severe trials it must be to those who live and die without any faith whatever in a kind and loving Providence. May God be with you and sustain you all, as I know he will. We are very glad, friend L., to know that you are feeling well enough to send us this message.

LOOK OUT FOR THEM!

Some time in November last we received the following:

> *Mr. A. I. Root:*--Please send us ten copies of A B C of Strawberry Culture, by Terry, at your earliest convenience, and at lowest rate.
>
> Our Country Home.
>
> 88 Fulton St., New York, Nov. 12, 1890.

Along with it came a very neat-looking rural paper, styled *Our Country Home*, affirming that they had a guaranteed circulation of over 100,000 copies monthly. We therefore filled the order. Since then we have sent repeated statements, and finally drew on them, as a last resort, telling them that we should publish them unless they settled up their little account of $2.05. As they do not even yet so much as "peep" by way of reply, we think best to give this caution. Perhaps we might add, that neither Dun nor Bradstreet quotes any such institution.

NO MORE HELP WANTED.

Please do not write us asking what the "chances" are for employment in our establishment if you move to Medina. It is not possible for us to give places to a quarter of the applicants right here at home, and I have repeatedly so stated in our county papers. Notwithstanding, people do move here and bring their families, sometimes waiting a year, and, in one or two cases, even two years, for a possible vacancy. Then they move away, and I fear they sometimes feel hard toward me. In view of this it seems to me the kindest thing I can do is to tell you that we have quite a bookful of applications all the time. If these people who apply for places were skilled mechanics in almost any line of trade, the prospect would not be so poor. But I believe that skilled workmen in any department usually have plenty to do, with good pay. I do not know what is going to happen to our people if this matter of serving an apprenticeship and learning a trade is to be abandoned entirely.

THE MICHIGAN FARMER, ON BUCKWHEAT.

An exchange says:

> The *Michigan Farmer* says that "it is very apparent that Japanese buckwheat is not going to take the place of American varieties." This conclusion is based, in part, on the experience of a correspondent who says, "The flour is dark, and will not bake good cakes;" and he can "sell it only for chicken feed." He adds: "I have raised it for three years, but am through now."

In commenting on the above, friend A. C. Bugbie, of Lochiel, Ind., asks us:

> What do you think of this? I have raised about 1500 lbs. of buckwheat flour this winter, raised from the Japanese variety, and it is of prime quality.

Well, friend B., I will tell you what I think the correspondent of the *Michigan Farmer* had better do. I think a change of cook for three years, rather than a change of buckwheat, would change his mind in the midst of these changes. The Japanese flour has been used, not only in our lunch-room, but all over Medina, for two winters past; and, besides that, we have reports from it from almost all over the world, and it certainly is not true that the flour made from it is in any respect inferior to the common.

A VISIT FROM MR. PARKS, OF THE G. B. LEWIS MANUFACTURING CO.

We have just had a very pleasant call from Mr. Chas. E. Parks, who is manager and largest stockholder in the G. B. Lewis Co. at Watertown, Wis. He has just been on a business trip to New York. On his return home he stopped at W. T. Falconer's, in Jamestown, N. Y., and after making them a call he dropped in upon us unexpectedly. Mr. Parks is a man of business, and a hustler. We were somewhat surprised to learn that they were turning out from 100,000 to 120,000 sections a day. These are all sawed on four automatic machines, the first of which cost the company $3000, and the next three about half as much each. They probably make twice as many sections per day as any other firm. Our output is from 40,000 to 75,000 per day. But the G. B. Lewis Co. make hives, frames, sections, and shipping-cases only, those being their specialties, while the rest of us who make a smaller number of sections per day are making every thing used by the bee-keeper, whether wood or metal. The company now employ about 125 hands. We are glad to add that the sections made by them are second to none in the market.

FOUL BROOD SPREAD FROM COMB FOUNDATION; IS IT A CAUSE FOR ALARM?

On page 447 of the *American Bee Journal*, Mr. S. Corneil, of Lindsay, Ont., Canada, holds the opinion that the disease may be spread in that way. He gives some interesting figures, showing the temperature at which spores and fully matured microbes may be killed. He says it has been ascertained that the death-point of the most resistant fully matured microbe is 140 degrees, and that the *spore* of said microbe could not be killed under a temperature of 257 degrees. Wax, he says, melts at a lower point than 145 degrees, and he adds that, in sheeting it for foundation, the wax is kept at a temperature as near the congealing-point as possible; and he concludes by saying, "There is good reason for believing that foundation has been sent out which has never been heated up to 190, much less to 257. It is highly probable that such foundation would contain germs of foul brood, if made from the wax of foul-brood comb." On the face of things this appears to be a pretty serious state of affairs; but, happily, the facts come to our rescue, and prove that there is no cause for alarm.

We have melted the worst kind of diseased combs in our large heating-tank, made foundation, and put it in our own yard, but no trouble ever came. And there is not wanting testimony from other experimenters to prove this. But if Mr. Corneil's theory be true, would not foul brood have been universally spread all over the land with the advent of comb foundation, years ago?

Now, friend Corneil, we do not wish to dispute you point blank, so we will explain why the disease will not propagate with foundation. All our wax is melted by steam, in a large vat holding over a ton. This vat is inclosed in another, and is therefore surrounded by water. We have just been down, and found that the temperature of this surrounding water was 200 degrees. After the wax in the inner vat is melted, this temperature is allowed to go down to about 180. We aim to keep the wax itself in the melting-vat at about 170 degrees, and this temperature is maintained for days. The supply of wax is kept up by putting in cakes at a time, and it is dipped out as fast as we want it. As Mr. Corneil himself admits, a long-continued high temperature is equivalent to a much higher temperature for a few minutes; and not only the microbes but the spores themselves have got to succumb. A few hours of 170 degrees, we know from long experience, will kill all sorts of germ life. While the wax in the *melting-vat* is kept at 170, that in the dipping-tank is kept very near the congealing-point, 140, sometimes as low as 130. But before it has arrived at the dipping-tank, it has long ago been thoroughly disinfected by the long-continued heat of 170 degrees. The Dadants have a similar melting-arrangement, and we feel sure that their foundation is perfectly free from any live germs. Perhaps we should remark further, that the wax melted in a solar extractor might not be disinfected, and it might be a wise precaution to remelt all such wax that has come from diseased colonies. But as there are very few apiaries indeed in the United States that have foul brood, no one need have any fear about the solar wax-extractor. It will *probably* kill the germs, but *may* not.

WHAT WE USE IS THE BEST.

We like to think that the things *we* use are the best. It is not comfortable to think that somebody else is using devices or implements vastly better than our own. We use and recommend the Victor Spring-fork Safety bicycle. *We* think it is the best of all machines of that description. But it may be it is because we own one, and do not like to think the other fellow has a better one. Those of us who have been using loose frames may feel a little uneasy in the thought that fixed frames may one day be *the* frame. It would be very expensive to change, and so we like to persuade ourselves that what we use is just as good, and a little better. Be that as it may, it is well we do not change at every breath of wind.

CLOSED-END FRAMES, AND CHANGING OVER WHOLE APIARIES.

Now that the advantages of fixed frames are being set forth, do not let any bee-keeper owning 100 colonies on loose frames be foolish enough to change over his whole apiary to that style of frame. It has been demonstrated over and over again, that bees will make honey for their owners, in loose frames and in fixed frames; and the frame we should use is the one that affords the most convenience and accommodation. The frame that the apiarist can manipulate the easiest and the most rapidly, will, of course, make a little more money for him, because less labor is required. We have mentioned this two or three times already; but for the sake of some who are too enthusiastic, or inclined to be hasty, we think it will bear repeating again.

WHAT IS THE MATTER WITH OUR PATENT OFFICE?

The other day an attorney sent us drawings and specifications of a patent that had just been issued to his client, on a bee-keeping appliance. Just out of curiosity we thought we would look the matter up, as we were sure it was old. We discovered that there were two other patents on the same thing, and the dates of the three patents are not more than a month apart, in the *same year*.

Somebody is going to lose money if one of the trio "goes to the courts." Now, this is not one instance, but one out of many that have come to our knowledge; and if any of our readers wish to know what the three patents are on we can inform them by letter; for, to make the thing public here, might make something of an uproar in camp. E. R. R.

LOOKING OVER BACK VOLUMES OF BEE-JOURNALS; A HINT TO WOULD-BE INVENTORS.

It is real fun to look back through the old volumes. Problems that now seem to be quite fully solved, were, years ago, discussed, and seemed to be in a maze of mystery. Verily the world is moving, in spite of the fact that sometimes we do not seem to arrive at the solution of many old problems. It is interesting to see how the Italians were opposed. By some they were accounted as almost worthless. Foundation was another thing that had to fight its way inch by inch, until it is now regarded as one of the indispensables. Even the honey-extractor was called a "honey-slinging machine," and was regarded as worthless. A glance through the old volumes shows us that what we regard nowadays as entirely new was invented, described, illustrated, praised, and condemned, years and years ago. When our editors declare a thing to be old, it almost gives offense. Those of us who aspire to be inventors, and to be the originators of something new, should first purchase a set of old bee-journals and look them over, and see what has been invented. A mere skimming will not answer. We must scan page by page and paragraph by paragraph.

SILVER-PLATING OUTFITS; MORE ABOUT THE LAKESIDE ELECTRIC CO., ENGLEWOOD, ILL.

Some of the friends thought I was a little hasty in pronouncing this whole business a fraud and a swindle from beginning to end. When I put in the caution on page 240, March 15, I felt satisfied that the whole thing emanated from J. M. Bain, Zanesville, O., as it had so plainly on the face of it the ear-marks of his plan of swindling. Just as we go to press we are informed that Postmaster-General Wanamaker has forbidden any mails to be delivered to W. H. Griffith & Co., Zanesville Chemical Co., Bain & Co., and J. M. Bain. All letters addressed to any of the above are to be returned to the sender. with the word "Fraudulent" stamped across the envelope. In one single day over $800 was paid out to Bain. The Englewood, Ill., institution is only a branch of the same concern. Bain has started out with so many addresses and so many different places, that one needs to look carefully before sending him money. As the U. S. courts are after him, his swindling is probably nearly if not quite at an end.

PRICE LISTS RECEIVED.

J. M. Young. Plattsmouth, Neb.
W. H. Bright, Mazeppa, Minn.
A. G. Hill, Kendallville, Ind.
W. H. Norton, Skowhegan, Me.
J. M. Kinzie. Rochester, Mich.
J. H. M Cook, 78 Barclay St., New York.
W. J. Valentine, Hagerstown, Md.
N. D. West, Middleburgh, N. Y., cell-protectors.
The following were printed here:
Leininger Bros., Fort Jennings, O.
S. R. Holbert, Monangah, W. Va.

CONVENTION NOTICES.

The Central Michigan Bee-keepers' Association will meet at Pioneer Room, Capitol, Wed., May 6, 1891. All are invited.
W. A. Barnes, Sec., Lansing.

The Bee-keepers' Association and Fair will be open May 6. Open to all.
H. Smith, Sec'y.
Ionia, Mich.

SPECIAL NOTICES.

THE HONEY-BEE.

The price of the above work by Thos. Wm. Cowan, mentioned elsewhere, will be $1.00, instead of 75 cts. as formerly announced.

FIGWORT, OR SIMPSON HONEY-PLANT SEED WANTED.

If any of you have any, even a little pinch, we should be glad to get it, as we are not able to furnish even the five-cent packages.

GLEANINGS IN BEE CULTURE

A JOURNAL DEVOTED TO BEES AND HONEY AND HOME INTERESTS.

Published by A. I. Root, Medina, O.

Vol. XIX. **MAY 1, 1891.** **No. 9.**

STRAY STRAWS

FROM DR. C. C. MILLER.

PLANT POSIES for your wife.

NO NEW BEE-JOURNAL has started for a week.

THOSE REPORTS on p. 289 are very interesting.

DWINDLING in Medina makes me keep my bees longer in cellar.

ESPARCETTE, spoken of on page 279, is called the honey-plant *par excellence* in some parts of France.

THAT SKELETON hand on page 258 has one joint less on its forefinger than on its little finger. Has it been fooling with a buzz-saw?

WHO CAN TELL, with some show of authority, which is worth more for spring feeding, a dollar's worth of granulated or brown sugar?

LOCATING HIVES on the south side of a building, very properly says W. S. Pouder, in *Indiana Farmer*, "is liable to give bees the swarming fever."

PHACELIA TANACETIFOLIA is making some stir as a honey-plant in Germany. I believe it comes from California. Can any one tell us about it?

FOUL BROOD. Chas. Dadant gives, in *A. B. J.*, convincing evidence that there is no danger of foundation carrying foul brood. I've breathed easier since reading it.

DR. TINKER ought not to tinker with our spelling. "Storey" is all right in England, but it looks funney here. It's too much labour. The spelling of our language is horrible, any way.

MAPLE BLOOM, my former guide for taking out bees, is unreliable. March 30 it was in bloom here, following which was cold weather, including a snowstorm which left the ground covered three days.

WINTER CASES, on p. 289, seem to beat chaff hives. But I'd like to see them compared in a hard winter, or in a colder place than Medina. Still, if the proportion were changed, and 14 in winter cases had died to 11 in chaff hives, I'd take the winter cases.

THE PACKING-BOXES of the Oatmans, referred to on page 267, I saw last summer. Certainly not all of them had bottoms, I think. They were three stories high, making 12 hives in a pile. If I am rightly informed, they lost heavily during the last of their wintering.

THE NON-SWARMING SYSTEM met my eyes in reading. I felt curious and interested. Then I saw it advertised by Geo. A. Stockwell, and I felt glad. I sent a quarter, got a pamphlet with less than would go on three pages of GLEANINGS. I read it and felt—humbugged.

"UNIFORMITY should be *the rule* in sections and crates, and any departure from that rule should be disapproved and frowned down." That's what the *A. B. J.* says in an editorial inviting a full discussion of the subject. Brother Newman, you've struck a good note.

COARSE WIRE CLOTH over entrances in winter is approved (p. 266) by Bro. Potter and the editor. Why, bless you, don't you know that I am with you, friend Root? I even go further than Bro. Potter, and have my wire cloth so coarse the bees can go right through it.

JOHN SMITH, in *Nebraska Bee-keeper*, doesn't believe in "fixed distances." He says: "I can set my hives near or far apart, and it doesn't matter to other folks either. If they don't like the looks of my yard as I fix my distances, they can go and fix their own distances in their own yards."

A NEW PROJECT is on foot in England to start a bee-paper. A stock company is to be incorporated with a capital of $50,000, in 10,000 shares of $5 each. Among the movers are J. Hewitt (a Hallamshire bee-keeper) and T. Bonner Chambers, of Sheffield, where the paper is to be located.

COOKING EGGS, as given on page 282, is good. Here's the way our folks do. Pour *boiling* water on the eggs, at the rate of a quart to a half dozen; *cover*, and set on the reservoir. In 10 or 15 minutes the yelk will be done soft, and longer will make it harder; but the white will not get hard in all day. It doesn't need such close watching as your way, Mrs. Axtell.

STARTING SEEDS, particularly fine seeds, in boxes. Bake the soil to kill weed seeds. Fine it, level in box, lay seeds on top, sprinkle fine soil over, just covering the finest seeds; lay brown wrapping-paper flat on it, and keep always a little moist. The paper holds the moisture, and prevents the seeds washing out when watered, besides the other good it does as a covering.

ROBBERS sometimes clean out a weak colony in spring. Whatever you do, don't take a hive away that the robbers are at work on. If you do, they'll only attack a neighboring colony. Take most of the contents out of the hive, but leave at least one comb with a little honey to finish. If you must take the hive away, put another in its place, with something for the robbers to work on.

PIPING of the queen, says Henry Alley, "is made by the rapid vibration of the wings before the queens leave the cells." He should have added, that the sharpest piping is made by the young queen at liberty. Wouldn't it be best to continue the old-fashioned way of saying that the queen at liberty "pipes," and the queens still in the cells with the coarser voices "quahk"? Cheshire says the wings have nothing to do with the piping.

REQUEENING. Alley says, in April *Api.*, "It will pay to requeen colonies each two years." Rambler says, in same *Api.*, "When a honey-producer advocates the requeening of all his colonies the second year, it seems to be an evidence of the inferiority of his system of queen-rearing and of his queens." That's rough on Alley, but he has lots of good company on his side, and I guess he can stand it.

GENERAL CORRESPONDENCE.

THE CAUSES OF SWARMING.

DADANT TELLS US WHY HE PREFERS LARGE HIVES.

About 40 years ago a friend of mine told me that he had seen a swarm settling on a rock in a waste land, about half a mile outside of the city in which I lived in France. It was at the beginning of April, and had I not known my friend as unlikely to tell lies I would have thought that he intended to make an April fool of me. After finding the swarm I covered it with a hive, and the next morning I brought it home. My business prevented me from looking at it before evening, when, to my surprise, I saw that most of the bees were gone, and that the few hundred which had not followed the others were unable to fly. They were starving. Then I concluded that this colony had deserted its hive for want of food; and this view was confirmed by several other similar experiences. On a Sunday afternoon, while glancing about my home apiary, I saw the alighting-board of one of the hives covered with fighting bees. The ground in front of the hive was already covered with dead ones. I stooped down, and racked my brain to find an explanation of the fact, for I had never seen any thing like that, when, on a sudden, a lump of bees larger than my fist dropped on my hat, and thence slipped upon the fighting bees. Raising my eyes I saw a swarm suspended under the limb of a tree just above. These bees were so weak that they were unable to cling together, and were killed by the bees of the hive in front of which they had fallen, little by little, in small bundles. I procured a hive into which I shook the swarm. They took the food that I gave them, and, after having regained strength, they departed. Had I given them one or two combs containing honey and pollen they would have stayed.

I have seen several colonies deserting their hives for want of honey, and especially of pollen. I returned them after having attended to their needs, and they were happy to stay. I have seen, also, bees deserting as soon as they were brought out of a cellar which had been too warm. For several weeks these bees had been anxious to have a good flight; their hives had been for them a prison, and they availed themselves of the first chance to depart.

All these occurrences, showing that bees swarm to find better abodes when they are dissatisfied with the circumstances in which they are, induced me to investigate the causes of natural swarming, which, so far, had been considered as a natural impulse given to bees in order to replenish the earth.

As bees generally swarm when their hives are full, the first thing to be considered was whether the lack of room was not the cause of swarming, especially as it is well known that bees in small hives swarm more than in larger ones. Now, the question arose: "How much room is needed to accommodate the most prolific queen?" For several years I kept an observing-hive, and had noticed that a good queen can lay about six eggs per minute, or 360 per hour. If we suppose that she lays half the time, or 12 hours in 24, we have 360x12, or 4320 eggs per day, during the best time of the season.

A well-known German bee-keeper, Mr. Von Berlepsch, having hived a swarm on empty combs, counted the eggs laid by its queen during the first 24 hours, and found a few more than 3000. But, having probably considered this number as unusually large, he did not draw any inference from it, for he did not enlarge his small hives. Yet, since a queen taken at random can lay 3000 eggs to-day, I can not see why she did not lay the same number yesterday, or why she will not lay as many tomorrow, if the circumstances have not changed. To verify whether a queen is able to lay 3000 or more eggs per day for several weeks, it is indispensable to give her colony a number of cells sufficient to receive her eggs for 21 days, besides the cells containing the provisions of honey and pollen.

I had several large hives built to produce comb honey in small boxes placed at both sides of the brood, after the idea of Jasper Hazen. I resolved to use them for my experiments. These hives could accommodate 14 Quinby suspended frames, 18x10½ inches inside; and my enlarged American hives could accommodate 16 frames. I filled these frames with worker combs and watched the results. We have these hives yet in our home apiary. I soon ascertained that these hives were too large, even for my best queens, whose laying, during the best seasons, exceeded 4000 eggs per day for 21 days, and I concluded that a Quinby hive, with 10 frames and a partition-board, would be sufficient. These 10 frames, containing 104,500 worker-cells, can accommodate the laying of from 3500 to 4000 eggs, leaving 20,000 or 30,000 cells for the provisions. All the Quinby hives that we have made since have 10 frames and a partition-board. These hives are larger than a 12-frame Langstroth; yet, every year, when the white clover begins to bloom, nearly every one of them is full of brood and of bees, ready to bring honey into the upper story, or to swarm, if we delay, even for very few days, the enlarging of the room.

In the spring of 1889 we had put our upper stories on the hives, as we usually do in the last part of May; but the bees, for a week or more, did not bring any honey, when, the wind having changed, we noticed a booming in the apiary. Two days after, although we had raised their hives from the bottom-boards, several colonies were gathered outside of their hives. Their upper stories, containing each about 50 lbs., had been filled in less than three days. We hastened to put a second story under the first; yet some swarmed — dissatisfied, doubtless, with these large hives which had proved too small to receive their daily crop. As it was impossible for us to enlarge the space in our six apiaries on the same day, we had an unusual number of swarms, 15 or 20 per cent, if I am not mistaken; more in our Langstroth hives, and such swarms! One of them was so large that we had to give it two upper stories on the evening after it was hived. The bees in these large hives were therefore as much crowded as a colony in a small hive; for it is not the size of the hive which excites the bees to swarm; it is the comparative narrowness of their abode; it is the lack of empty cells to receive the harvest and the eggs of the queen. When the honey comes in slowly, the enlarging of the room with empty frames may suffice; but when the crop is very abundant, as the workers do not like to remain inside to build combs, while the nectar abounds in the fields, they swarm.

Most bee-keepers think that our hives are too large to raise comb honey; furthermore, a great many have reduced their Langstroth hives to eight frames. But when we made our experiments, the extractor was not yet invented; and for several years after its invention, as extracted honey was difficult to sell, we raised comb honey, in small boxes first, then in 3-lb. Adair sections; and our crops were not smaller in quantity than those of bee-keepers using smaller hives, whose apiaries were in the same lodition as ours.

One of the advantages of large hives is, that their queens, during the summer, have a great many empty cells in which they can lay, and the workers a large space in which they can lay up a quantity of fine summer honey for winter.

I know that both these propositions are in direct opposition to the new doctrine which advises the bee-keepers to contract the brood-chamber so as to stop the laying of the queen, and to compel the bees to bring all their harvest in the sections; but I know that our crops, even when we raised comb honey, gave us more profit with less work, and fewer chances of loss, than the narrowing method to its partisans. A queen, from July to August, can lay very little in a small hive; and as the workers do not live, on an average, more than 35 days during the working season, the number of bees is very much reduced in the fall. When winter comes, the population, which is small, suffers proportionately more from the cold than a larger one. In spring the bees are slow in recovering a number of workers sufficient for the harvest, and their owner is compelled to narrow up the brood-chamber to force them in the sections. Thus the advocate of small hives turns in a circle. His colonies are small in winter and spring, on account of his summer contraction; then he is compelled to contract his hives again to get a crop. On the contrary, not only the queens in our large hives are not hindered in their laying; but the workers have a large room in which they lay up an abundance of the best provisions. Then the population well fed, able to keep well warmed, coming out in spring numerous and healthy, fill their hives with workers ready for the honey-harvest.

A successful Italian bee-keeper, who was converted to the large hives by my writings, wrote, last year, in *L'Apicoltore:* "To obtain good crops of honey you should prepare your colonies during the preceding summer." Contraction does just the reverse. Our experience on the question of the size of hives continues the same. In our Lamont apiary (see GLEANINGS, January 15, page 60), we have about 30 large Quinby hives and 23 ten-frame Langstroth. Last October all our Quinby hives but three had sufficient stores for winter, while 19 of the 23 Langstroth had to be fed. Yet we did not take an ounce of honey from their brood-chamber in summer. For several years we had intended to transfer their colonies to Quinby hives, and we have resolved to do it this spring.

But, to return to my subject: Natural swarming can be caused, also, by the death of the queen during the honey season. Then the workers, if they have eggs or young larvæ, raise several queens; and the first hatched, being hindered by the bees from killing her rivals, is dissatisfied, and goes out with a swarm. This swarming we designate as a "primary swarm with young queen." Such swarming with young queens amounts, on an average, to two or three per cent of the number of our colonies. It shows that it is impossible to prevent natural swarming completely, unless you watch your colonies to prevent them from replacing their queens during the honey harvest; but it confirms my theory, that swarming is always caused by the uneasiness of the bees.

Hamilton, Ill., Apr. 16. CHARLES DADANT.

[Friend D., I am well aware there are many things to be said in favor of large hives; and where one works for extracted honey, as you do, I rather think I should prefer them. As this large amount of room is needed, however, during only a part of the year, there are some very good reasons for enlarging, when needed, by an upper story; and if we do this, it behooves us to have our frames rather shallow. This is why Langstroth decided on the frame he has. Using ten combs below and ten more above, we have a hive about as large as most bee-keepers care for, and it comes in good compact shape, pretty nearly a cube. It is true, the boys have of late very strongly favored an eight-frame hive; and for comb honey, where we wish to oblige the bees to put all the surplus into the boxes above, an eight-frame hive may not be so bad. And, again, for those who sell bees and ship whole colonies, eight frames are about all that is really necessary to ship and pay express charges on. I have for years noticed that bees do swarm, both in season and out of season, when their home is not to their notion. I have seen nuclei desert their hives, apparently because they were pestered by a nest of ants. I have seen them do it, also, when I could see no other reason than that the entrance had been carelessly left too small for them to go out and in comfortably. They swarm out when the hive is overcrowded, when out of stores, and in glass observatory hives when they have too much light, or if the sun makes them uncomfortably hot, etc.]

UNITING WEAK COLONIES.

DOES UNITING PAY DURING SPRING DWINDLING?

On page 290 of GLEANINGS for April 1st I see that some spring dwindling is experienced at the "Home of the Honey-bees," and in this connection I see that the editor advises uniting weak colonies which have the "spring dwindling," unless the weather is warm and pollen is abundant. This is going back to the plan of the "books" on bees of years ago, where they told us the time to unite was when it was discovered that any two colonies were too weak to be of use alone. There is no question but that the uniting of two weak colonies to make one strong one is profitable to the apiarist; still, that uniting must make the *one* better than either of the *two* would have been when the honey harvest arrives, or our labor of uniting is worse than useless. That the uniting as proposed by the editor does not, as a rule, make the united colony better at the end of three weeks than each would have been if left separate, is why I object to the advice there given. Years ago I experimented along this line to my entire satisfaction, and I have put as many as seven such "spring-dwindled" colonies into one hive, the seven making a good rousing colony at the time, and in a month all were dead; while some, no stronger than some of the best ones put into this hive, which were left separate, pulled through and built up into colonies. The idea seems to be, that, where two or more such colonies are put together, the bees seem to think that they can do something "big," and so work themselves up to great activity in starting a large lot of brood, which wears out the little vitality there is left in them before enough young bees hatch to take the place of those wearing out daily; hence all perish; while, if they had been left to themselves, they would have been less active, the few young bees which hatched would have taken the place of those which died, and, when settled warm weather came, the few young smart bees which were in the hive at that time would and could care for a large lot of brood in proportion to their numbers, so that the colony would build up for the next winter if nothing more. I once had a colony get so low in this way that there were, by actual count, only eighty odd bees the fore part of June; and yet this little colony, without any assistance from any other colony, built up into a good colony for winter, and gave two of the large old-fashioned sections of nice sealed buckwheat honey. Dr. Miller and several other of our best bee-keepers have reached the same conclusions regarding uniting spring-dwindling colonies that I have, if I am not mistaken. By confining these small colonies to as few frames as they can cover, and building them up as fast as possible when it comes warm weather, and *then* uniting them just before the honey harvest, has given me splendid results in honey, as I have given in back volumes of our bee-papers.

LARGE SWARMS TO PREVENT SWARMING.

I see Mr. Robbins, Mr. Dayton, yourself, and others are discussing the swarming question, along the line of large hives, etc., you claiming that it is the large hive used by the Dadants and Bro. France which give them so little swarming. Now, it seems to me that, from the light of the past, no one can deny that your position is right; for, away back when our lamented Quinby wrote his "Mysteries of Bee-keeping Explained," he told us that a hive of 4000 or more cubic inches filled with comb was almost an absolute non-swarmer, bees staying in such hives for years without swarming. I quote from memory, and have not tried to get the exact words. No one, so far as I know, has any trouble, to any extent, with swarms when working for extracted honey, which working always demands a large amount of comb space, if we are to have the best results. But the real point at issue, as I look at it, lies in the fact that no *best* results in *comb honey* can be secured and use a hive containing from 3000 to 4000 cubic inches in the brood-chamber, or that amount of space filled with empty comb in early spring. Quinby told us that a 4000-cubic-inch hive filled only a third full of comb the previous season, would just as surely give a swarm before more comb of any amount was built, as would a hive filled with comb one-third this size, and this brings the thing down to just where we find it in working for comb honey. We have the small hive filled with comb, and the sections without comb; or, if you please so to term it, a three or four thousand-cubic-inch hive, one-third of which is filled with brood-combs and the rest with sections, in reality empty as the bees view it, and swarming is the result. Should we fill our 2500 cubic inches of section room with sections filled with empty comb, on the "continuous-passageway" plan, we should not have any swarming. But, alas, we do not wish to do this, for reasons too numerous to mention here, and so it comes about that he who works for comb honey must expect to have swarms; and, if I am correctly informed, the Dadants and Mr. France are as subject to them as any of the rest of us with the few bees they work for comb honey, whenever they work for the same. The trouble seems to be, that we sometimes confound the working for comb and extracted honey, so that the reader is perplexed to know our meaning. If my memory serves me rightly, I have never had more than three swarms from all the colonies I ever worked for extracted honey with my small brood-chambers; and years ago I produced extracted honey by the thousand pounds. A non-swarming hive for comb honey is a desirable thing, but something not yet brought about. G. M. DOOLITTLE.

Borodino, N. Y., April 15.

[Friend D., I have had just the same experience you have in putting a number of sick or diseased remnants together. At other times I have surely saved weak colonies by uniting. Where one has quite a few bees, and no queen, and the other has a queen but not the bees, it will surely pay to unite them, and we may often discover weak colonies that may be united with queenless ones; for during dwindling, queens have a way of disappearing suddenly, as well as bees.]

SWARMING AND THE HONEY-HARVEST.

HOW MAY WE GET THE MOST HONEY WHEN BEES SWARM DURING THE HONEY SEASON, AND KEEP DOWN INCREASE AT THE SAME TIME?

Does swarming during the honey-flow necessarily diminish the quantity of surplus gathered? that is, can we get as much comb honey as we could if they would work right on without swarming? I think *I* can, but it is not as easy to tell *how* to do it as it is to tell how not to. When a swarm comes off, hive it in a full-sized brood-chamber, and set it on a new stand. When the lower story becomes full, put on empty surplus arrangements. Let the unfinished sections on the old colony remain there. Hive the after-swarms, and treat them as you do the first ones. The chances are that the sections given the new colony will be finished long before those on the old stock, and very likely the latter will never be finished at all. Just follow up that system, and I promise you will get less than half a crop; and if the season is a very short one you will get little or nothing, when I may get a very fair return.

I would rather my bees would not swarm very much, because of the watching and labor involved. But they will swarm, and that right in the midst of the honey harvest, as I presume is the case wherever clover is the principal source of supply. And as I can not prevent it, I have been driven to study and practice methods to overrule it and the effects thereof. I have been so successful, that, so far as the quantity of honey they will give me is concerned, I would as lief have my bees swarm as not; and at the same time the increase in size of my apiary is very moderate.

A swarm of bees embraces much the larger share of the field bees of a colony, and are, in fact, mostly of that class. Quite a sprinkling of bees of a younger age are, of course, present; and, when hived on the old stand, that number and the number of field-bees will be somewhat augmented. All this, together with the fact that being thrown out on their own resources appears to give them an added incentive to action, puts them in the very best condition to make every lick count. They will accomplish more then for a while than at any other period.

I hive my swarms on some old stand, of course. The original purpose of that was to prevent after-swarms; but it becomes, in fact, but one of its two principal purposes. The other is to get as large and permanent an available force of workers in the new colony as possible. I consider the stock from which a swarm has issued as virtually of no account for comb honey the rest of that season. If they swarm again they are of but little use, and they are worth no more as a colony if means are pursued to prevent swarming. Hence I want to get all the bees I can into the swarm. I then shall have recruits there to take the place of the old ones as they drop off. But in place of setting the new swarm on the old stand, I carry it to the stand of some other colony that has lately swarmed, or that of some weak colony. In either case I set the displaced colony down beside it, with the entrance turned at right angles to it. I adopted this method in the effort to prevent absconding of swarms. Now, please do not laugh at me, but I do believe that bees look up a location before they go off. From the evidences, I think this is often done, if not usually, after the swarm issues. While I find the expedient does not always prevent them from coming out of the hive where they are put, so far in the two seasons I have practiced it, none have shot right off for the woods. Removing the swarm to another stand gets them where the prospectors can not find them to lead them off.

Having disposed of the swarm, I remove the case or cases of sections to the new colony. If the swarm is very large, or the cases pretty well filled, I put on an empty case underneath.

The size of brood-chamber into which we put our swarms is an important item. My verdict is emphatically for contraction. I am troubled much with absconding of swarms; but while I have suspected, I can not find any good evidence that contraction has any thing to do with it. I generally hive on five frames, with foundation starters. I have not tried frames filled with foundation enough to know whether that would affect the honey-yield. Hutchinson has tested both methods, and he says use only starters. Wired frames and full sheets have objectionable features to me. I like my system —contraction—so well that I should be very loth to give it up after six seasons' practice.

The above I believe to be in detail the two great essential principles of the only profitable system of comb-honey production where swarming must take place during the honey-flow. For me, swarms thus treated give as much honey as colonies that do not swarm at all—the latter, however, being greatly in the minority.

Now, what do I do with the old colony? Well, if I do nothing else with them I remove them in a few days to another stand, or set them on top of another colony. I take a great many of them to pieces, and use them by frames to form nuclei, or to build up other nuclei or weak stocks. But more than any other one thing, I carry the frames or hives to the upper story of some other colony, and run it for extracted honey. I find it necessary to raise honey in both forms to supply my trade. But I keep very few empty combs for that purpose. I think it much better to do as I have stated. It keeps down increase to some extent, and I get a benefit of the combs I could not otherwise. I confess it is slower work to uncap these combs, as the surfaces are more or less uneven. Sometimes I unite two old colonies, after a queen gets to laying, by shaking the bees off one set of combs on to the other hive, then put on sections when there is a pretty good prospect of getting something from them. But more often I go through these old colonies some three or more weeks after swarming, and extract the honey from all combs half or more full, and they have usually gathered considerable by that time.

After the clover harvest is over and the surplus cases are all off, I take out the dummies and fill up with frames from these upper stories, nuclei, and old colonies that I have yet left intact. The bees then have full breeding capacity, and room to store honey for winter. And, by the way, I can not see but that my bees winter as well on fall honey as that gathered early in the season. I unite more or less in the fall, as conditions seem to demand it.

CLOSED-END FRAMES; WHY NO BEE-SPACE IS WANTED BACK OF THEM.

Ernest, on page 211, hardly states just the reason why I want no bee-space back of closed-end bars. It is simply this: I do not want them there when manipulating frames. They are of no use there, and they are a nuisance. In removing hanging frames, especially with one hand, it is a wearying effort, when a hive is pretty full, to avoid crushing bees, and then I can not always do it. One end is pretty apt to be heavier than the other, and then they will not hang even; and even if they would, to raise or lower a frame in exactly the right line to retain the true bee-space is the hardest matter of all. Now, if I can just slide the end along the end of the hive, especially if one end overbalances the other very much, it makes it more easily and quickly done.

COST OF TIN AND ENAMELED-CLOTH HIVE-COVERS.

I have just been figuring up the relative cost of the two styles. I find that, exclusive of paint, the enameled-cloth covers will cost about 3¼ cents, and tin about 6½ each, aside from freight charges. The former will take more paint and more time to fix, which may make it cost from ⅗ to ⅔ of the latter. In addition to that, paint will not adhere to tin or any other very smooth non-porous surface very well; whereas, spread on the wrong side of enameled cloth it is a fixture, making the latter much more durable. Still, I have have not actually tested tin. In the main I have nothing over my covers, just because I do not need any thing.

GEO. F. ROBBINS.

Mechanicsburg, Ill., Mar. 23.

FLOATING APIARIES.

FURTHER TRIALS OF THE SCHEME, AND THE RESULTS.

Several facts in regard to the ups and downs (especially the *downs*) of migratory and non-migratory bee-keeping have recently come to my knowledge that may be of interest to those inclined to try the experiment of obtaining more than one crop of honey in one season. Some time in December, 1890, friends Stevenson and Deemas, of near St. Charles, Mo., started with about 125 colonies of bees, mostly Italian, in excellent hives, and well equipped for gathering a fine crop of honey, and increasing to any desirable extent, with some imported and Doolittle queens, for New Orleans or vicinity, on the steamer City of Baton Rouge. By the way, that is the very boat on which I, on several occasions and on different trips, shipped from 300 to 400 colonies of bees at a time from New Orleans to St. Louis. On the way the steamer struck an obstruction, and boat and bees went to the bottom, our bee-friends barely escaping with their lives. I sincerely sympathize with our unfortunate friends, for I have been through the mill myself, and know just how it is and how they feel; for, among other great losses, one of these same Anchor Line boats was the cause of the loss by fire of nearly 300 two-story Simplicity hives filled with fine Italian bees, with 20 frames to each colony. Nothing daunted they procured a fine lot of about 150 colonies of bees from friend D. McKenzie, of Camp Parapet, La., and took them to a point on the river, at or very near the same spot where Perrine, of Chicago, once had a large apiary. The prospects for a good crop of honey were fair, when, a few days ago, a break occurred in the levee from the great pressure of the high water. A crevasse was formed, and it was with difficulty that our friends saved their bees by hastily moving them to the levee. Of course, their prospect for a crop of honey now is a very slim one, with water from 5 to 15 feet deep for miles in every direction around them, and they will certainly have to move the bees to some other locality, and quickly, too, involving more labor and expense, if they expect to get any honey down there this spring.

Some of your readers may remember that, in a former article, some time ago, I mentioned friend E. Stahl, of Kenner, La., as having 1000 full colonies of bees, in one yard, and as having secured a large crop of honey from them. Well, it seems that the flowers down there last fall, while blooming profusely as they do up here quite frequently, yielded no honey; and the result is, that friend Stahl (so I am informed) has lost 800 out of 1000 colonies, by starvation. This is a good illustration of the uncertainties of migratory bee-keeping; for had any one taken several carloads of bees (as I once did) down there, prepared to secure a big crop from the fall flowers, he too would have had to feed his bees to keep them alive (at a loss, of course), or let them starve, as friend Stahl did; and let me say that this is one of the snags that our bee-friends, who favor migratory bee-keeping, will run against much more often than they think for.

As regards friend Stahl's loss, from which I know personally of him he will not care greatly, he will simply cut the combs out of the frames (not try to save them from moths, and fill them with bees again as we would do up here) and render them into wax, and stack hives and frames away (to use again), and in an incredibly short time have them all roaring with bees again; for if there is one man in the extreme south who understands southern bee-keeping, and understands how to make it pay at the least cost of material and labor, and who is always enthusiastic in regard to bee-keeping, and seldom discouraged, that man is (as I knew him) friend Stahl. E. T. FLANAGAN.

Belleville, Ills., March 28.

REARING QUEENS UNDER THE REGULAR BROOD-NEST.

ANOTHER HAS TRIED IT, AND FINDS IT WORKS.

I have reared a number of fine queens this spring, under similar conditions to those given by Dr. Miller, on page 270. To explain more fully, I will state that I use a two-story eight-frame hive for a brood-nest up to the time our harvest comes, when I contract to one section by means of a plain zinc queen-excluder, and at the same time raise the upper story and place between it and the lower one a set of empty combs or frames of foundation, always seeing that the queens are below. Now to the point. This spring, not having enough queen-excluders to go round, I placed upon some 18 or 20 colonies a case of partly drawn sections (left over from last year) between the two upper stories and the brood-nest below, thinking this would cause these sections to be filled quickly, and also discourage the queens from going above. I was right as far as getting the sections filled; but about half of the queens went up and established their brood-nest in the upper stories, and in all these cases the bees built from three to a dozen queen-cells below. Most of these I removed and saved, but left one cell in each of five or six colonies, and in due season I found laying queens in these; and it was surprising to see how quick they filled those eight combs with brood. At this point queen-cells were started. So I removed this lower brood-nest and placed it upon a new stand, giving it a case of empty combs, and in the course of a week those new colonies were in good shape to store honey. Now, all the while these young queens were below, the old ones were doing good work above. You may be sure this gave rousing big colonies just when they were needed; but during our orange bloom it set in to rain, and kept it up steadily for two weeks, which caused us to store two-thirds of our crop from this source. During this rain, these large colonies built from 12 to 15 frames of nice combs from one-inch starters, and also managed to store an average of 25 lbs. of honey each, while average colonies built only from 3 to 4 of combs, and did not get any surplus honey. I should have mentioned above, that these large colonies were in hives tiered four stories, besides the case of sections mentioned, and that the combs were built in the upper stories, and also that they would average about 25 per cent drone comb. This is doing well considering the conditions they were built under just before the swarming season. The queens were about one year old, part Italian and part hybrid.

Huntington, Fla., April 5. A. F. BROWN.

SAFEST METHOD OF WINTERING.

CELLAR PLAN PREFERRED.

Mr. Root:—I have been very much interested in reading the opinions of many of your subscribers as to the best and safest way of wintering bees, and I will not undertake to say which of the many are correct, as the locality may have something to do with their success. It may be well in large apiaries to experiment and test the different plans recommended, as the loss of a few stands to them would hardly be noticed, while the beginner in experimenting might lose all, or so cripple his business that it might take years to recover.

It might be advisable for beginners, and those having a limited number of stands, to retain the old and tried methods until they become satisfied that a change will be more satisfactory, taking into consideration the climate, location, and length of winter, which should be carefully studied. In this latitude and locality, cellar wintering has given the best results. I have wintered in the cellar for eight years successfully, and at no time has the loss exceeded ten per cent, while the average would fall far below. One year ago I tried the experiment of wintering nine stands outdoors in single-walled hives packed with chaff and straw, and well protected from the winds by a grove on the north and west. All went into winter quarters in splendid condition, with plenty of stores, and in the spring only one stand was left to tell the tale of outdoor wintering in this locality. Those wintered in the cellar came out in splendid condition, without the loss of a single stand.

Last year, Dec. 2, I put 30 stands into winter quarters in the cellar, all in fair condition, while some were in the very best condition. My loss was one stand. Twenty-nine stands came out of the cellar in good condition April 6th, and to-day are gathering pollen from the maple and box-elder.

My plan has been to place the stands in the cellar in the same condition as when prepared for winter, leaving the cushions and covers on. As soon as they get settled down a little, remove the cushions and covers, leaving the hive entirely open at the top, and the entrance open the same as in the summer, with bottom-board left on, and leave them in this condition until about two weeks before time to take them out in the spring, then replace the cushions and covers.

Your plan of removing the bottom-boards only may be equally good, but I doubt whether you will have very much better success in wintering; yet your plan will allow a greater number of stands to be wintered in a smaller room, on account of being tiered up. In leaving the hive entirely open at the top, it allows the steam or animal heat to pass off, while the plan of having the cover remain on the hive would, it seems to me, have a tendency to create moisture on the under side of the cover, consequently dampness in the hive. I observed this by placing a piece of burlap on the hive after removing the cover, allowing it to remain for several days, and then on removing it I found that it was wet; but whether the moisture came from the bees or from the cellar, it matters not; it would have the same bad effect on the bees. The old saying, "Never swap horses in the middle of the stream," holds good with me in this case until another plan proves equally successful. N. H. BELL.

Wahoo, Neb., April 9.

NUBBINS.

PROF. COOK GIVES US SOME VALUABLE THOUGHTS.

Friend Root, please do not call my brevities "Stray Straws." It does me too much honor, and our dear friend Miller injustice. Just dub my driblets plain nubbins.

Glad to hear what Dr. Miller says of melilot, as demonstrated in France, especially as we are going to give it a big trial at the station here. We are going to test its value for honey, for food, green and dry, and for silage. We are also going to test rape along the same lines.

I must say that I am with Bro. Newman on the editorial "we." Dr. M., you know what the good Quaker said to his wife—"My dear, everybody but thee and *me* is peculiar, and I sometimes think thou art a little singular." Now, when the doctor assaults universal custom—in other words, attacks essays at conventions on this "we," he is certainly the singular man. "*Honest Injun*," doctor; isn't it suspicious when you and I are the only ones in all the great human family who are right?

Friend Corneil is usually about right, but, without doubt, drew it too fine when he was going to have foundation sow microbes broadcast. Long experience says, "No, no."

You ask what I think about bees disliking red. If it is true, I should say it is a case of bee-taste. I say, *if true*. I have a friend who wears a red shirt habitually in working with bees, yet rarely ever gets stung. I had always supposed that bees were indifferent to color, though much annoyed by any roughness like fuzz on rough woolen cloth. I have heard it said, that bees dislike dark colors. I never could see that my bees objected to my dark clothes, unless rough and fuzzy. Why may not bees have taste? I like to see a girl, if a bright brunette, dressed in bright red; if a blonde, in light blue; so, as I have taste in such matters, far be it from me to deny a like peculiarity in bees. Sir John Lubbock's experiments plainly show that bees can distinguish colors, and what observing bee-keeper doubts it?

I don't wonder, friend Root, that you hesitated at the snake-story. But I have seen it, and so know that young "saugas" do run for protection into the maternal mouth. You ask about the breathing. I think snakes can manage for some time without breathing. In our own case I do not suppose cessation of breathing would be fatal till the heart should stop beating, which, with us, is in a very brief time. Not so the snake. I have known a snake's heart to beat for hours, even after it was taken wholly out of the body. Insects are like snakes in this respect. They will live a long time in a very small close box. I never looked in to see where the snakes went to, but I suppose they went to the stomach; indeed, some years ago some of our students killed a massasauga, and actually reported finding the young snakes in the mother's stomach. I feel quite certain that I have seen more than a mouthful run into this opening.

I always supposed that the very low gentle hum of bees in winter was only a note of "all right;" but a louder one, a murmur of "too close, more ventilation." I have often quieted bees by opening the door on a cool night.

Mr. E. France makes a good suggestion regarding wax secretion. I shall try some experiments to prove or disprove his theory. In case of Mr. Doolittle, I do not think the facts are with him. Bees often do go loaded with wax when swarming; but may they not have remained quiet before? we know that they do rest somewhat before breaking up the old home; and surely if hived on full combs, the wax scales disappear at once. I doubt whether Mr. Doolittle has the truth on his side.

Why does our usually correct friend speak of the scouts looking up a new home while the bees are clustering? As I state in my Bee-Keeper's Guide, I think the bees cluster to give the queen a rest after trying her wings, which are unwonted to labor. I supposed it settled, that bees look out a home before the swarm issues. They certainly do sometimes; and if so, I guess always.

Mr. Cowan is usually very accurate; but, is digestion separating the food? I should say digestion is rendering food capable of being absorbed, and that absorption did the separating. I wish to say, as I do say in my last edition of Bee-keeper's Guide, that Cowan's book is very excellent, and, I believe, *very correct*.

Friend Root, don't misunderstand me regarding granulated sugar for winter food, I believe, that, if fed in the fall, it is a superb food for bees. In this case it is digested, and is probably equal to any honey, and superior to much honey as a food; but I don't believe that it is a good food for bees, if fed exclusively while bees are in confinement, either in summer or winter. I think your experiments should be more extensive before you speak *ex cathedra* on this point.

Our bees wintered nicely on a diet of almost exclusively fall honey. Yesterday, Apr. 17, they worked in full force for the first time on soft maple. They got the first pollen April 13.

Ag'l College, Mich. A. J. COOK.

[I am very glad, friend C., that you are going to test rape and melilot. Tell me when they are furnishing honey to the best advantage, and I think I shall be along to see it. See article on page 360, in regard to melilot and alfalfa.—It occurred to me, too, that, if that red ribbon had been a little fuzzy, or if the bees found some stray ravelings, the latter might have accounted somewhat for the number that pitched into it. Yet I think the color *must* have had something to do with it.—Thank you for the instruction on just the point that seemed so strange and astonishing to me about the snakes when they were swallowed. How long did these young saugas stay in the maternal mouth? If you can not answer. I wish some reader of GLEANINGS would, at the first opportunity, test the matter, watch in hand. Now, please do not think me irreverent if I suggest that, in our recent studies about Jonah, I kept wondering how life was preserved when absolutely deprived of air; and is it not a little queer, that, in so many of these Bible miracles, we sooner or later find something somewhat parallel in the present existing order of things? These snakes stopped breathing, at least for a time. Well, when snakes go under water they also stop breathing—that is, they stop *one* kind of respiration.—While dictating the above, a bystander tells us about seeing a mother-snake swallow a lot of little ones, after which she crawled into a log. The boys plugged the hole up so she could not get out; and after school they split the log open, and killed the mother, and found the "juveniles" still alive. So this answers a part of my question.—We are glad to know that the bees at the college came through all right.]

ALFALFA AND SWEET CLOVER IN KANSAS.

SOMETHING SPECIALLY FAVORING SWEET CLOVER.

The writer of the following letter sent us an order for 100 lbs. of Bokhara, or sweet-clover seed. As this aroused our curiosity we wrote him, and he replies as follows:

It may be of interest to you to know what it was wanted for. Two years ago two neighbors (living ten miles from me) each bought a sack of alfalfa seed and sowed on their farms, which joined. The one came up and furnished a great amount of feed the first year. The other got but little or no feed the first season. Both fields bore purple or similar blossoms. The plants were somewhat similar, only that one grew very large, and fed a great many hogs. The crop was cut three times, while the other seemed to be getting root. The second year one field bore white blossoms; the other, the same as before. Upon investigation one plant proved to be sweet clover, the other alfalfa. The gentleman who had the alfalfa said the sweet clover double discounted any plant he ever saw for forage; that stock did well on it; that it produced well on ordinary land, of a dry season, and he was very anxious to get some of the seed. As I wanted something for hog-feed, I told him if he found any to let me have some. But on examining your catalogue which you sent me, I found you quoted the seed, and I ordered immediately, and then notified the gentleman of my action, and told him he could have 50 lbs.

I may not be satisfied with my venture. I have since been told by men from York State that it is a bad weed, impossible to get rid of, and that nothing will eat it; but I shall sow all the same. I have been in this country 32 years, and have had much experience with cultivated grasses. I have tested some kinds that were pests in the east, and they would not live long in this climate. Our soil is good enough for any thing, but it wants a peculiar grass to stand the climate. Any plant does well in a moist season, but we have dry hot seasons that kill any grass I ever planted. The native grass of the country always lives through and keeps green, and gives good pasturage and some hay. C. C. GARDINER.

Bradford, Kansas, Apr. 21.

THE NEW WATER CURE.

RENDER UNTO CÆSAR THE THINGS THAT ARE CÆSAR'S, AND UNTO GOD THE THINGS THAT ARE GOD'S.

Among the great numbers of letters that have been received in regard to this matter, there are perhaps half a dozen who suggest that Dr. Wilford Hall has not received quite the credit that belongs to him. Our friend Freeborn, on page 377, suggests something of the kind. Three or four think it is not quite clear that I was justified in "breaking my pledge,"* etc. As this matter of charging several dollars for information that can be put into a very small pamphlet, or perhaps on a single sheet of paper, is a thing that comes up every little while, let us consider it a little. Some years ago Herman Flick advertised artificial honey, and made great claims in regard to its wonderful excellence, and the cheapness with which it could be manufactured. I sent him $2.00 for the secret; but as soon as I received it I found he had *copied* it from *Dr. Chase's Recipe Book.* I do not remember whether I signed a promise not to tell or not. In fact, it *does not matter* particularly. I found him to be a humbug and a swindler, and it was clearly my duty to publish him as such, because he was *obtaining money under false pretenses.* The "pretenses" were not only *very many*, but they were *very false;* had it actually been a *new discovery*, the case would have been very different indeed. Some tell us that Dr. Hall is a *good* man, but that it was only an error in judgment. Where a man, by "errors in judgment," takes a great many thousand dollars out of his *neighbor's* pockets, and puts this money into *his own*, it begins to look a little as if there were something more than mere error in judgment. Well, let us drop the past and call it square. Let us say he deserves what he got, in view of the good he has done. How about the present? Dr. Wilford Hall's agents are canvassing with greedy haste almost every town in the United States; but as soon as one of our little tracts gets into the town the business is done up, and the agents gather up their circulars and depart to some place where A. I. Root is unknown. They have even gone to California, and the friends of justice are following them there with the little pamphlets. Now, can Dr. Hall and his agents be Christian men, or even honest men, when they continue to receive $4.00 from each individual for something they know is being scattered abroad all over the land free of charge? Who will answer? What excuse does Dr. Hall make for such a practice? Why, the only excuse he possibly can make is to *deny* that his discovery was in print previous to 1850. See the following from his journal, the *Microcosm*, for April:

> Now, to nail this villainy, and put a padlock on the pens of the scamps referred to, we will pay E. D. Scott one hundred dollars in cash if he will show us any publication, however obscure its author, which sets forth the essential details of our Health Pamphlet, bearing a date earlier than that of our discovery, said date being proved to be authentic, and not cooked up by some miscreant to serve a rascally purpose.

I have right here in my hands, while I write, Fowler & Wells' Water-cure Manual, by Joel Shew, published in 1847.† I do not want the

---

*Dear friends, I have broken *no* pledge. I have not copied from Dr. Hall's pamphlet; I have only copied what I found in Kellogg's doctor book and the Water-cure Manual.

†Among the readers of GLEANINGS we have one whose *grandfather* was *Joel Shew's brother*, and this friend promises us some valuable facts in regard to his great-uncle's experiments.

hundred dollars, but I do want Dr. Wilford Hall to stop his highway robbery; and I hereby give him warning, that, unless he does it at once, I will lay the whole matter before the Postmaster-General, or other proper authorities. How much Christian spirit do we find in the little extract I have given above? Well, there is considerably more than a page of abusive slang, very much like it. The Water-cure Manual contains one whole chapter on this matter of internal water cure, and much of it is so exceedingly valuable that we shall probably give it in our next issue. The press of our country is now quite generally active in exposing Hall. Several papers have copied our little tract entire; and we call upon the journals of our land to help put down this extortion and fraud.

Of course, Dr. Hall is not the only one engaged in this same swindle. Great quantities of circulars have been sent out by one Lemke, Menominee, Mich. I wrote him at once, asking him if it were the same thing as Dr. Hall's secret. After waiting some time for a reply, and receiving none, I sent him $2.00 (his price), but I did *not* sign his promise or agreement; therefore I can give you the whole of it, without leaving grounds for any one to say that I have broken any pledge. We make extracts of all we consider of any moment, as follows:

LEMKE'S MEDICINELESS PRESCRIPTION FOR THE CURE AND PREVENTION OF DISEASE.

The large intestine is about five feet in length, and it may be filled in an adult so as to present a circumference of twelve inches.

The colon is that part of the large intestine which extends from the cæcum to the rectum, and which is divided into three parts, distinguished as the ascending, the transverse, and the descending. Here is where the excrementitious matter discharged into it by the small intestine acquires the fæcal smell, which increases the longer it is retained in the colon.

It may as well be admitted first as last as being true, that almost all ailments which afflict humanity come from impurities or disease germs, microbes, or parasites, which are carried in during respiration and secure a lodgment and enter into the vital circulation, only if they find a diseased spot favorable to their propagation, or from the impurities that enter into the vital circulation from what we eat and drink. These impurities may come directly from unwholesome food we eat, or indirectly from the absorption into the the circulation of disease-bearing germs, which arise from the stench of the fetid matter which a person carries in the colon. The quantity so carried about, whether there be a regular daily movement of the bowels or not, is estimated at from one quart to two gallons. Who would, for a moment, carry about or sleep with such an enormous mass of putridity and disease-bearing stench if a way could be suggested by which it could be got rid of without making the organs do it by drugs or laxatives?

Who would not gladly embrace the opportunity of adopting an agreeable, harmless, benefiting treatment by which this awful disease-producing, dangerous, foul, disagreeableness is directly removed, while, at the same time, all soreness, stiffness, fevers, and inflammations are driven out of the system? This I propose to do, and am successfully doing right along, by injecting into the rectum hot clear water, enough to fill and distend the colon, or flush it, the same as you would flush a sewer that is clogged up.

PRESCRIPTION.

Buy a rubber fountain syringe at a drugstore (or for $1.50 we can send you one) that will hold two quarts or more. Screw a hook into the ceiling above the foot of your bed; pour into the bag of this syringe two to four quarts of clear water, so hot that you can just bear to hold your hand in it without being scalded (never use cold or tepid water). Insert the rubber stem of the syringe into the rectum; hold the water there for 15 minutes, if possible, and roll about on your bed, when you will be ready to discharge this enema, together with the entire contents of the colon.

Those suffering with Bright's disease or other kidney troubles, or inflammatory rheumatism, piles, inflammation of the bowels, or other organs, should inject a second dose of half the quantity of first dose of hot water into the rectum, and hold it there against all efforts to break away, and go to sleep with it. After a few hours you will be ready to expel it through the kidneys and bladder.

DOSES.

Children, 1 to 5 years of age, 1 pint; from 4 to 15 years of age, 1 to 2 quarts; over 15 years of age, 2 to 4 quarts.

Persons ailing should take this treatment once a day before retiring to sleep; those in good health should use it every second or third evening.

SNAKES IN CHINA.

THE LARVÆ OF BEES AND WASPS A DELICACY.

Friend Root:—When one is off on a tour, and sits down to eat all alone, GLEANINGS is a good thing to read between bites, and make one feel as if he had good company. But to-day I happened to open a number in which Prof. Cook gets enthusiastic over snakes, which are not so appetizing as bees and honey. I, too, can tell a snake story.

Last summer I was strolling in a wild glen, seldom visited by man, along a path made by wild pigs, when a loud hissing startled me, and there on my right, about four feet away, was a large snake slowly coiling itself. Being empty-handed I sprang forward; and, a tough little vine catching my foot, I half tumbled, half pitched, about five feet down a steep bank into a tangle of viny bushes, from which I crawled out with a sprained knee that has made me a cripple for six months. The only good way out of the glen was past where the snake lay. He was coiled up where I first saw him, not in a pile, but round and round, flat on the ground, his triangular head resting on the central coil. He was very nearly the color of the ground, and in the shadow of the overhanging thicket, with his body flattened down close to the ground, I could but just clearly make out his outlines from ten feet away, though he was as big around as my wrist, and fully four feet long. I saw that he was too far away from the path to reach it at one spring, and began to move forward slowly, when, without an instant's warning, his head was 18 inches up in the air, and coming at me with jaws gaping almost six inches wide. He struck out only about two feet; but the suddenness of it made me spring back, and, tripping again, I tumbled over on my back. Then I got up; and, going down the glen a little way, I climbed up to the path and limped home. I think that snake would make a valuable addition to Prof. Cook's collection, and I am sure I wish he had him.

It seems strange, that, in so densely populated a country as this, wild beasts should still be common; but so it is. Where I am to-day it is market day, and I have seen three antelopes and one armadillo carried past, and have myself just dined on a golden pheasant. In this region, when the rice is in the milk, the farmers have to guard it night and day from the ravages of the wild pigs. A few Sabbaths ago I was holding meetings in a village near Shaowu and was told that, early in the morning, a tiger had eaten a sow. She had been turned out at daybreak, and, not coming back to her little pigs, the men went to look for her, but found only the remnants of a tiger's feast. Later in the day I saw the tiger's tracks, and measured them with a tape-measure. They were a strong five and a half inches broad. Such a beast would eat up a pig just as a cat would a rat.

Once as I was approaching a village I saw a number of men coming from off the hills, armed with hoes and sticks, and was told they had just been chasing off a tiger. I have never yet heard of a man-eating tiger in this part of this province. The nature of the country here, narrow valleys between high hills, and the absence of freezing cold winters, favor the increase of such "varmints," while superstition hinders somewhat their extermination. Poor weapons and ignorance of natural history aggravate the trouble. Once on a mountain path I saw a snake and asked a Chinese brother, "Have you poisonous snakes here?" After a short silence he cautiously replied, "On the hills we dare not speak carelessly." He is a good man, nevertheless. When he began to read his Bible at home his mother gave him forty blows on each ear as hard as she could lay on, first one hand then the other, and he, a man grown, took it all as meekly as a lamb. But now he is high in her favor.

I have written how Chinese bees will come and locate in curious places; but, alas! they will go just as they come. This summer I visited the places where I saw the bees under the bed and under the counter; but they were gone. In both cases the owners said the bees went off of their own accord; and Mrs. Whitney's "self-come" bees went off in a body one day last summer, leaving a lot of empty combs badly infested with moths. So far as I know, the Chinese use honey only as a medicine; but the larvæ of bees, or of wasps either, are considered a very dainty morsel.

I have just astonished a Chinaman by telling him that, even in silvery America, the lazy and careless come to want. J. E. WALKER.

Shaowu, China, Feb. 21.

HIVE RECORDS.

WOODEN POINTERS INSTEAD OF BRICKS ON HIVE-COVERS; A GOOD SUGGESTION.

During the past year there have been several articles from extensive bee-keepers, describing their methods of keeping a record of the condition of each hive by means of stones or bricks placed in various positions and on different parts of the cover. Now, I think I have a better way. Nail or screw three small buttons, each 1½ or 2 inches long, on the cover of each hive—one in the center and the others in the corners of one end. Let one represent the queen, one bees and brood, and the other honey. Each button may be turned to point in each of eight different directions; that is, toward each corner, and half way between these. Each direction has its meaning, and a single glance tells the exact condition of the colony the last time it was examined. I think the buttons superior to bricks or stones, because they are easier to operate and are less liable to be knocked out of place; but principally because, in removing the cover to examine the colony, no special care is needed, while with bricks or stones they must first be removed, or the cover handled very carefully to prevent changing their positions. Where a person is handling 200 or more colonies, something of this kind is needed to economize time, and this method seems to me to have more points of excellence than any other I know of.

M'INTYRE'S UNCAPPING-BOX.

This, as described on page 769, 1890, strikes me as being just exactly the thing for the large honey-producer; but I think an improvement could be made by dividing the box horizontally, the meeting edges to be beveled, the upper into the lower. The box would still be solid and firm; but removing the upper half would greatly facilitate taking out the drained cappings.

J. WEBSTER JOHNSON.

Tempe, Arizona, March 30.

[You have given us a good suggestion in regard to pointers fastened on the hive-covers. I had thought several times of adopting a similar plan. When working over a hive I usually sit on the end or side of the cover; and, of course, slates, stones, or other such memoranda as are held down by gravity, in obedience to the same law are displaced, and I have got to remember to put them back just as they were, or slightly modified to indicate the changed condition of the colony. Now, your pointers would not be disarranged at all, and could be made for an insignificant sum of money. For record-making on hives, we want something that we can read and see at a distance, just as we would tell the time of day on a clock-face by the figures, so far distant as to be almost undiscernible. Your suggestion in regard to the uncapping-box is a good one, I believe.]

E. R. R.

LADIES' CONVERSAZIONE.

BUILDING UP WEAK COLONIES.

MRS. HARRISON HAS NOT BEEN VERY SUCCESSFUL IN IT.

Mrs. Axtell, at our last conversazione, said, "I know of nothing that a woman can work at, and make pay better, than to take those weak colonies under her wing and nurse them into strong ones, by the time the honey harvest comes." I've done a good deal of this nursing business, and I never worked at so low wages at any other kind of work. I barely earned the water that went into my soup. Of late years I do all my spring feeding in the fall, and very little of it then, for the Illinois River bottoms have never failed to furnish a flow of honey in the fall, that I know of. When I put on Hill devices I tell the bees that they have plenty of honey to last until fruit-bloom, so good-by. After our bees were all taken from the cellar, Mr. Harrison said, "I wish you would look into that colony of bees nearest the grape-arbor, for they are weak, and I am afraid that they are starving." I was sorry that I knew that there was a weak colony of bees; but as I had promised the minister to "obey," I went and examined them and found plenty of honey, but only about a score of bees and a queen. I covered them up and left them until the afternoon, when it was quite warm, and opened the hive again, and was delighted to find out that the bees had departed for fresh fields and pastures new. I took out the combs, trimmed off all excrescences like old queen-cells, scrubbed the hive with brush and hot suds, rinsed with boiling water, and, when dry, put back the combs and carried it into the cellar to remain until I had a swarm to run into it.

I've tried every way that I ever heard of to build up weak colonies. I've given them capped brood, and I've brushed off young bees from combs belonging to strong colonies, and picked up the downy ones and given them to the weak, and I did more harm than good. I should have had more bees at swarming time if I had let them alone. It is not pleasant to talk of our failures, but open confession is good for the soul. Will Mrs. Axtell tell us how to build up weak colonies? I've confined them to a small space in the hive, with a nice clean comb of sealed honey, and tucked them up warm; but failure would result.

I've been practicing water cure for many years, in curing the ailments of my family, but novices should look a little out or they will do more harm than good. A specialist of the eye and ear told me lately that washing out the nostrils with a douche will inflame the ears, and my experience corroborates it.

Peoria, Ill., April 21. MRS. L. HARRISON.

[Mrs. H., while many of us have had an experience much like your own, we have also, at different times, had experience like Mrs. Axtell's; at least, I think most of us have. We thank you for your concluding caution.]

A NEW MEMBER TO THE LADIES' CONVERSAZIONE.

SUCCESSFUL WINTERING IN RICKETY HIVES, ETC.

I am very happy to notice in GLEANINGS a ladies' department, where we all can air our views on the different parts of bee-keeping, besides rendering assistance to each other in many ways. I shall beg to sit on the lower round of the ladder, and listen to the higher lights above me, that have had the practice and experience; for that is what we all require to be successful in any undertaking; it may seem very pleasant to hear one tell how to do this and that, but it is quite another thing when we do it ourselves.

I have only a few colonies, commencing with one in the spring of 1889; last year increased to seven, this spring dwindled down to three; have lost many bees, but gained much in knowledge and experience. I fed them in the fall, but very late; did not take the frames out to be sure they had enough, for I was afraid to handle them. There is an old saying, that "misery likes company," and I presume to say, that there are many as badly off as myself.

GLOVES.

I have a pair of rubber gloves that I have used some, but dislike them very much, as they cause the hands to perspire, and are very clumsy. A few days ago I changed two of my colonies into new hives and used some common gloves partly worn out, that were made of pigskin. They are thicker than the common kid—something like dogskin, with large loose wrists. I got a few stings where the fingers were worn thin; but they did not trouble me as on the bare hand. I use a hat with common window-screen wire around the rim, four or five inches deep; below that is mosquito-netting, gathered at the bottom with an elastic cord.

HIVES.

I read about hives with double walls and dead-air spaces, and have come to the conclusion they all amount to nothing, unless two important points are observed; first, a large strong colony; second, plenty of good food, that will last until they gather pollen. My reasons for thinking so are these: I have a friend (a lady) who raises bees, and, having a surplus, wished to dispose of some of them. I thought there might be a chance to replenish some of my empty hives; but when I saw them I almost stood aghast; some of them hung with one hinge that would hardly keep the door fastened; and one was a low square box, I might call it punk (that means rotten wood). It looked as if one should point his finger toward it, it would collapse. I did not purchase, for it was eight or nine miles from my home, and I knew I never should have courage to move them in such dilapidated hives. Now, will you please inform your readers what kept sixteen out of seventeen colonies alive through this hard winter? I think it must have been strong colonies, and plenty to eat; they certainly did not lack good ventilation. MRS. W. H. BENT.

Cochituate, Mass., Apr. 20.

[Mrs. B., your point, that good strong colonies, with plenty of stores, often winter nicely in the most rickety and exposed situations, is by no means new; and a good many times rickety hives winter all right when the others do not. This points strongly toward the necessity of an abundant ventilation of some sort, either bottom or top, especially when bees are exposed to the severity of the weather outdoors.]

HOW TO KEEP ON GOOD TERMS WITH OUR NEIGHBORS.

SOME EXCELLENT SUGGESTIONS FROM MRS. AXTELL.

We should follow the rule that Christ has laid down—to "love our neighbors as ourselves;" and if our bees trespass upon our neighbors, let us make good the harm and annoyance they make, not only by sending them cakes of honey, but by exhibiting neighborly kindness in many ways.

Soon we shall be setting our bees out of the cellar. Those of us who have near neighbors should send them word that we are about to set them out, so that they may not wash on such days, as it is very annoying to the good housewife to have her clothes all specked up, and her newly washed windows dotted. It is better to meet our neighbors more than half way in the matter of keeping peace, rather than getting their ill will, as it costs much more in dollars and cents in the long run, and kills all our influence for good over them and their children, and destroys our happiness and peace. It is no more than right to pay our just debts, that we send them liberal amounts of honey occasionally—yes, quite often, as our good neighbors seldom let us know when and how much our bees have annoyed them. How bothered they are with the bees around their horse and pig troughs! and even the little drinking-vessels of the children are at times swarming with bees. I don't know that they ever at such times sting the chickens, but they frighten their owners. The bees seem to prefer to frequent different places for water, even when they have an abundance at home in troughs of easy access.

There are many ways that the bees annoy our neighbors that we never know of—hanging around the milk-troughs; stinging the little folks as they tramp upon them in the damp places in the back yards; following the men while at work in the fields, sometimes, though more than likely it was some other neighbor's black or hybrid bees instead of our gentle Italians. Yet, because we have so many bees we get the credit of the annoyance. A few pounds of honey will sweeten the otherwise bitter feelings, and cause only good will and kindly feelings. Generally the neighbor will repay much of the gift in sending back in return something we appreciate as much as the honey, or doing kindly deeds.

We need not send our first-class section honey. Broken pieces or bulged honey, if nicely laid on a plate or in a bright tin pan, will be appreciated just as much. Often so kindly a feeling will arise that the neighbor will ask for broken or bulged pieces when buying, to help us make sales of it, realizing that it is just as good honey as whole sections.

In planting an apiary we should place the hives as far from the public highway as possible, and have them convenient to care for; also protecting them from the gaze of the public by planting a thick and quickly growing row of trees, or making a high board fence. I prefer the trees, as they are so much more handsome, and more permanent. We thus throw the bees so high over the road that passersby can not meet them in passing, and hide them away, as it were, from the public gaze. Many people are as afraid of bees as of death, almost; and if they were not where they could constantly be seen, they would pass by and not think of them.

We used to be so proud of our bees that we thought it nice to have them near the road, and to have people look at us while working with them. One Fourth of July a large swarm came off just when an open carriage of people was passing. The man put his whip to the horses, and drove right through the swarm, as it flew low. The people were very much frightened, but no harm was done. Another man, who often passed by, we noticed would always pull his hat low down over his face, and ride quickly by.

One day one of the commissioners of the highway politely notified us to move our bees into a back yard, and further from the road. We promised to put up a high board fence, or plant a thick row of trees, if that would answer. The trees were immediately planted about two or three feet apart. They quickly made a hedge, as it were, which threw them entirely above the road, most of the bees preferring to leave the apiary in another direction, rather than fly over the hedge of trees. Since then we have had no one find fault in that direction. In following the above suggestions we shall not be apt to need the aid of the Bee-keepers' Union very often, though it is a grand organization, and every one who has bees would do well to join it, as there are many unreasonable people in this world, and we can never know when we are safe or when other people have their rights. We need the Union to decide what is right.

At one time we were about to lose money by an unjust commission merchant. This was before we joined the Union. We made mention that there was such an organization, and he had better do what was right. The result was, he paid us $30.00, which we probably should have lost. I felt that it was a little deception on our part, but the organization did a good work for us, and is doing a good work, and is a blessing to those who are not members as well as those who are, as they promise to help only those who are members at the time of the trouble. It costs so little to be a member, I wonder that every one who owns bees does not join.

Roseville, Ill., Mar. 14. Mrs. L. C. Axtell.

AN UNPLEASANT EXPERIENCE WITH RUBBER GLOVES.

A GOOD SUBSTITUTE.

Twelve years ago I became much interested in bees. I subscribed for Gleanings and the A B C, and other publications; I also ordered a Quinby smoker, and a pair of rubber gloves from A. I. Root. I prepared a hat and dress for the work. I had previously purchased three colonies of bees, thinking I was making a good begining. I bought them for pure Italians. I could not then tell as to their purity, but they proved themselves good workers and good —stingers. It was amusement for me to look over my bees and look up the queen, especially if I had visitors. They must see my yellow queens. Soon my gloves were rotted by perspiration. The rents would come, and with them the stings. I would try to patch them, but they were so rotted and soft that the threads would not hold. I would try again and again, not knowing what could be better than rubber gloves. My hands would be so swollen I could hardly draw off my gloves, wet with perspiration, and covered with numerous new rents and stings. Discouraged and almost sick of my bees (for stings affected me very badly for the first year or two I worked with them), I went to Sherburne and bought a pair of boys' sheepskin gloves for 25 cents. I soon had them on trial. The bees literally covered them with stings, leaving their stings with the gloves. I thought I should soon lose all my bees in this way. Necessity is the mother of invention. I took honey and beeswax melted together. Then I rubbed my gloves well with this preparation. I had no more trouble, and have used such gloves ever since. I have worked the whole season without a sting on my hands. The Quinby smoker and A B C proved very useful to me. I have read Gleanings ever since, and would not be without it as long as I am interested with bees. I am pleased with the opportunity of visiting with my bee-keeping sisters through Gleanings. Mrs. Oliver Cole.

Sherburne, N. Y., Apr. 14.

COVERING FOR THE HANDS.

The discussion in Gleanings on this subject is very interesting to me, as my greatest objection to bee-keeping is, that I can't keep my fingers clean. I like best to have my fingers free, as I can work so much surer, and am not so apt to let the frames slip; but as we run mostly for extracted honey, it is hard work to keep the fingers presentable during bee-time. I have tried cotton and buckskin gloves, but we like woolen mits better than any thing else we have tried. They are made of rather coarse white woolen yarn, with long wrists, coming well down on the fingers, and ribbed all the way. They make a very good protection for the hands. The bees don't sting through them very much, and they are not uncomfortably warm. We lap and pin the bottom of the sleeves, then draw on the mits. They are tidy, and no bee can get in. But who can tell us the easiest way of getting the fingers clean? Or could we learn to work quickly and surely with the fingers bundled up? Once I had a pair of black mits, but they made the bees so angry we could not wear them. Mrs. M. A. Shepard.

Barry, Ill., Apr. 19.

ASBESTOS PAINT NOT SATISFACTORY.

I noticed in Gleanings, Mar. 15, A. W. Lindsey wants to know about asbestos paint. I have used it on hives, but I do not like it. It does not last. The last hives I painted I got lead and oil, etc., and mixed my own paint, and it is much better.

APRONS.

As aprons seem to be the topic, I will say that I get brown checked shirting. It is thick enough to protect my dress, but not so heavy and warm as bed-ticking. I have never worn gloves. I never thought I could work with them, but I wish I could, and prevent tan on my hands.

Benson, Vt., Apr. 7. Mrs. L. S. Austin.

THE BEES OF THE OLD WORLD.

P. H. BALDENSPERGER TELLS ABOUT THEM.

If we draw a diagonal line, beginning at Genoa, in Italy, and ending at Tripoli, in Africa, across the Mediterranean, we find the bees east of this line inclining to the yellow race—Italy, Greece, Turkey, and Egypt having the banded bees, while Tripoli, Tunis, Algeria, Morocco, Spain, and France have the black bee. Just as the banded Italian differs from its fellow-insect in Egypt, so does the black of France from that of Tunis and Tripoli. On the north of the Mediterranean the Alps are the limits, while on the southern shore the Lybian Desert forms a barrier. Again, if we compare all countries where Mohammedanism has had its sway for any length of time, we find those countries lying like a big crescent, one tip beginning at the Pyrenees, the concave line running down below Italy, and mounting again to the Bosphorus, including Greece. These have hives lying horizontally, and, as a general rule, worked more humanely than those in the region of the "cross." Italy forms the vertical axis; the hives stand upright, and the bees are sulphured every autumn, to take away all wax and honey. In southern Europe the bar-frame hives are finding their way with great difficulty.

In the south of France, the bee-keepers (or, rather, keepers of bees, for there are none that are real apiculturists) possess between five and one hundred hives, which they keep in long square boxes about three feet high and one foot broad. The top is nailed with a board, while the bottom is open, and put simply on a flat rock or stone, the unevenness of which forms different flying-holes. Some are also kept in hollow tree-trunks with big flat stones on the top, on an inclined plane for the rain to run down, and, at the same time, by its weight to keep the hive from falling in case of wind. Generally they place them against a wall to shelter them from the north and west winds. They expose them to the south or east.

It is a very curious sight to see a number of those hives standing upright and irregular, just as a flat rock may be right or left, up or down, in crooked trunks, with huge stones on top. I confess the apiaries away in Palestine or on the borders of the Nile, or in the wild recesses of the Atlas Mountains in Algeria, do not present such a novel and altogether savage aspect as does such an apiary in a civilized country, where every thing is flourishing except apiculture. How often, since I have been wandering about the Provencal Alps, and finding such neglected apiaries, have I put the question to others as well as to myself, "Why is apiculture so low in such a beautiful country abounding in fruit-trees, red and white clover, thyme, rosemary, heather, and a deal of other plants too varied to enumerate? They are free from taxes. The only answer I invariably got was, "The cruel winter kills so many bees, thus discouraging the farmers." I came across an old bee-book, written by an "Abbe Della-rocca," in Syra, in the Grecian Archipelago, and printed in Paris in 1790. The book is very ably written —or, rather, the three volumes—and it seems that, more than a century ago, the bees were treated here just the same as they are now; and the desolate priest says the cause of neglected apiculture in France is because the noblemen had a certain right on bee-hives; and, second, when the farmer could not pay the heavy taxes asked for the treasury, the tax-gatherers would take away his hives to fill up the sum. Disgusted with such robbing they finally gave up bee-keeping. Since then the French Revolution has put a stop to all these abuses; but still, apiculture has not come to its bloom. It was inevitable that the discouragement should then become so general that a century has not sufficed wholly to wipe away the bitter feelings that have so fast taken root in the French country people.

The way they now work the hives is as primitive as can be imagined. The swarms are lodged in a box or trunk of a tree, as above described, and left alone. In autumn all hives are visited, and 75 per cent are left untouched "for seed," as they call it. The other 25 are sulphured, and the combs, with the honey, sold to dealers who come yearly to buy all they can. The 75 are the stock left to swarm the following spring. Such hives are full of honey and pollen, and are capable of giving good swarms. This part is very humane, but not very remunerative to the owner. If the 75 have wintered safely, a good stock and strong apiary follow next year. They never (but in a very few cases) take out a part of the honey. In consequence of such treatment they want no smokers, no veils, and, generally speaking, no bee-keeping utensils. The honey and wax merchants are expert in this kind of apiculture, and take the hives destined to be sulphured to death, and weigh them. They then deduct the possible weight of the empty hive, and pay for the wax and honey per pound. They scrape out comb, honey, and dead bees, and put the whole into wooden tubs, taking as much as 150 lbs. of comb. The hives are then covered, and they thus go around from one apiary to another. When the wagon is well loaded they drive home. The comb is now broken up into the smallest possible pieces, and put into a stone trough having a wooden sieve at the bottom, thus permitting only the honey to pass; and by an outlet into a receptacle, such a trough may easily take over a thousand pounds. This first honey is sold on the market as virgin honey, mostly stored away in wooden barrels holding between 140 and 190 lbs. of honey. The residue of the trough is now put into flat baskets, having a small opening at the top to introduce the comb; and half a dozen such flat round baskets are now put under a large press, with a big wooden screw acting on the pile of baskets. On top of the baskets a board is laid to produce equal pressure. The honey from this pressing is impure, and is sold as second-rate honey in the same receptacles as the virgin honey. A good deal of honey is sold to the factories of Montelimar, Ardes, Aix, Nimes, Narbonne, etc., where honey-cakes are made. No Frenchman will pass his Christmas without having a taste of these honey-cakes, called "nongeats." Hundreds of thousands of pounds are consumed yearly. They are made of honey, sugar, and almonds. The trouble is, they keep only during the cold season. As soon as the hot weather comes on they begin to flow. Thus they are sure to be fresh every year. The comb pressed out is now put into a big caldron, and boiled. When it is well fluid this is put into the same baskets again, which are now furnished with long straw, and, as quickly as possible, put under the press again, and received in wooden receptacles. While the pressing is going on, boiling water is poured over the pile of baskets to keep the wax flowing. In some cases the farmers do the whole work themselves, pressing out the honey with their hands, and putting the boiled wax into a sack, and twisting at both ends to get the wax out. This wax is generally of a nicer color, as being better strained, while the honey is not as pure, having a mixture of pollen, wax, etc.

The bee in the south of France is black, showing some white bands at the first and second rings. The fuzz is strongly inclined to yellow; a slight tinge of orange marks both sides of the first ring. Very few men (as a rule no bee-keepers) have any movable-bar-frame hives, either Langstroth, Abbott, or Bastain. None of them have an extractor. They can have only a very little more honey than the "fixists." About Toulon, Cannes, and Nice, they move their bees on muleback to the higher Alpine regions in summer, putting the hives individually in sacks. tied at top. In autumn they bring them back again, and then take the honey in the manner above described. In Nice a single woman had a bee-hive in a cork-oak trunk, only the bark being used as a hive. She was selling comb honey right out of the hive. The bees, naturally enough, had been sulphured previously. The hive was well filled with sealed comb, and might have contained 40 lbs. of honey. No robbing was going on, as the hives are kept at some distance from town; and even Nice had such weather in January as to keep bees at home. They seldom have ice here, though. Flowers are sold all the year round. Foreigners from England, and even America, flock here in winter.

Ph. J. Baldensperger.

Marseilles, France, January 11, 1891.

[And so, friend B., honey-cakes are not a modern invention, after all. We are very much obliged to you for the birdseye view you give us of bee-keeping in the Old World; and we hope our friends mentioned by you will soon get into the modern ways, and throw aside their brimstone and rude hives.]

AN INTERESTING LETTER FROM CUBA.

500 COLONIES OF BEES IN ONE APIARY, WITH A PRODUCT OF 70,000 POUNDS OF HONEY IN A POOR SEASON.

Friend Root:—Another year has gone, and left behind it one more short crop. As this was the first season since I came to Cuba, when I have had what I called bees enough in one apiary to test the honey resources of any one locality, I naturally feel disappointed that the weather was such that it was impossible to arrive at any thing like an accurate estimate of what 500 colonies of bees in one apiary would do. Well, now, for the results. We began extracting Nov. 3 (that is, to go over the bees and take out what old honey they had left over from the summer, which amounted to only 500 pounds). The season was opening up fairly well, and the bees did well through November, we taking 10,400 lbs., an amount never before taken in the month of November. The first ten days of December we took 1200 lbs., and with us we think by the 10th of December the season is hardly begun; but on that very day a cold wave struck us, and for 47 days the wind blew from the north, cold, cold, every day. The cold weather in England, France, and Spain, did not spend all its force there; but in crossing the Atlantic it seemed to have got the "grip," and for eight weeks it held us Cubans with a grasp we could not shake off. The records show this last winter to have been the coldest since 1855. Now, from Dec. 10 to Jan. 27, 47 days, is the heart of our surplus season. To prove there was something wrong, look at the record of the last two years. The fall and spring of 1890 and '91 (then we had about 300 colonies of bees) in November we took 3600 lbs.; this year, with over 500 colonies, we took 10,425 lbs. Last year the first ten days of December we took 3275 lbs.; this year, 1200 lbs. Last year for the month of December we took 19,000 lbs.; this year for the same month, 24,400. Last year in Jan. we took 25,500 lbs.; this year, same month, 19,025. Last year in Feb. we took 5500 lbs.; this year, 10,400 lbs. Last year in March we took nothing; this year 6150, making for the crop 70,250 lbs. By looking at the amount of honey taken in the two last seasons, and comparing dates, you will see that, up to the 10th of December (when the cold weather began), we had taken 22,400 lbs., against 6875 lbs. for the same date the year before. Then you will see, in January we took only 19,025 lbs. against 25,500 lbs. the year before, and we consider January much the best surplus month of the year; but it was too cold this year.

I think I told you last year, that, when the business here is so managed that two good active men can take care of 500 or more colonies in one apiary, and take 75,000 or 100,000 lbs. of honey, then the business would pay. Now, with such a winter as this last one has been, we have produced 70,000 lbs., and at this date our bees are in fine condition, with hives full of bees and honey, and swarming daily. Does this crop and the conditions under which it was taken, prove to the advocates of 50-colony apiaries that 550 can be made to pay all under one roof, and controlled by one management and set of hands and fixtures? Results have placed it beyond the reach of doubt. It is no longer a question, "Will it *pay?*" but, "How can we best take care of the crop as fast as it is stored, with the least possible outlay of money and manual labor?"

Give me a common Cuban winter next winter, and if I do not produce 50 tons of honey from one apiary, then it will be very much different from what I expect: for I know this last one has been but a very little more than half a crop. This result has been obtained against the advice of all the novices and the would-be experts, both in Cuba and the U. S.—men who knew as much about the honey resources of Cuba as I know what the strides in the science of electricity will be in the next 50 years.

THE HOFFMAN FRAME NOT SUITED FOR CUBA.

You have called for an expression from "Southern bee-keepers" upon the Hoffman frame. I do not like the frame for Cuba nor for California. I can not do any better than add my testimony to that of W. W. Somerford, of San Miguel. I could not bother with such an arrangement here. We could not get out 50 frames a day here, where the bees glue every thing fast, unless there is plenty of room for them to pass freely all around. Then they will not stick them. When I first came to Cuba in 1883 I was prevailed upon to bring some of the Hoffman frames; but after a trial I took the hatchet and made open top and side frames of them, and have not tried any since. We have our frames hung on tin rabbets that are thin on the edge, so there is no chance to stick them. You know we have to go over our bees every week. Well, to go over 550 colonies in six days, and extract the honey by hand, there is no time to lose in fussing and prying to get your frames out of the hives. I would not for the world say any thing against the closed top and end frame in localities where there is hardly any propolis; for those that use and like it would get mad about it.

TWO VS. SIX FRAME EXTRACTORS.

There are many things used in small apiaries that would hardly do for us here. We have to adopt the fixtures that arrive at results with the least possible waste of time. For example, this year we ran two six-frame extractors and a comb-cart holding from 80 to 85 combs; and, had the winter been like those I have seen since coming here, we should have been behind in getting the honey out of the way of the bees; but as it was, we kept up with them very nicely. We could hardly think of depending on a two-frame extractor to throw our honey out; and for a man to think of carrying the honey in a hand comb-basket would be as discouraging as the other.

THE FUTURE OF CUBAN HONEY.

Friend Root, as we go on from one year to another in any business, we arrive at conclusions as to whether the enterprise is paying or not, and the probable outlook for success in the future. I started with this business here when it was indeed an experiment—when the movable frame was a wonder in the eyes of the Cubans; when all you could get for a gallon of honey was 35 cents; but now it brings 50 cents net (for we get pay for all the packages); and if the duty is ever removed, so that when you fellows get short we can send you a little to help you out, why, then we shall get more. So after the experience of the years I have been here, I can not but feel the greatest confidence in the future of Cuba's honey crop. It will go on and ultimately reach that grand climax that is enjoyed by him or that country that stands upon the top round of the ladder. The business is passing into the hands of the actual producers—men of more or less experience in honey-raising, and as such is always a step in the right direction, and it can not but result in a permanent good to the business and all concerned. A. W. OSBURN.

Punta Brava de Guatao, Cuba, April 8.

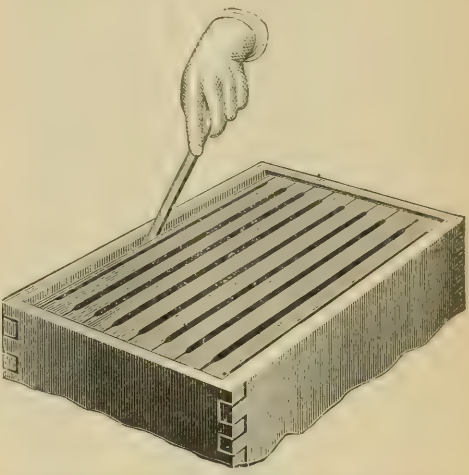
[You ought not to complain very much about your past season as a poor honey year. It may not have been up to the previous year, but 70-000 lbs. of honey—my ! you ought to be satisfied. Honey seasons in most localities are a variable quantity, you know.

I am glad of your testimony in regard to Hoffman frames for Cuba; but, say, don't your tin rabbets get filled with propolis if you have so much of it? Our hybrids have done it for us more than once, and we can get along with Hoffman frames. Don't get the idea into your head that Hoffman frames are used by *small* bee-keepers. Hoffman himself has some five or six hundred colonies on them, and there are other bee-keepers who have two or three hundred colonies on them. In regard to propolis, I saw as much in the region where nearly 10,000 colonies are used successfully on closed and partly closed end frames, with success, as I have seen in any part of the U. S. I believe there are very few places in the U. S. where, because of the excess of propolis, Hoffman frames can not be used. Some parts of California and the southern part of the country may be among the excepted localities.] E. R. R.

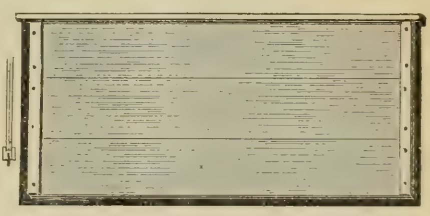
THE HOFFMAN FRAME.

HOW THE INVENTOR USES IT, AND HOW ITS MANIPULATION COMPARES IN SPEED WITH THE LOOSE FRAME.

Friend Ernest R. Root:—My hive holds eleven frames without spacing-board; but to handle frames fast there ought to be at least one spacing-board and one frame less in the hive, which will give room to handle and get the frames apart without removing any from the hive. For separating and closing up partly closed-end, or the so-called Hoffman frames, I use a stout screwdriver or chisel, which, in closing them up, is inserted between the spacing-board and hive-wall, and with a single motion the frames are pressed together firmly (see cut). In this way the whole set of frames, or any number of them, can at any time be shoved from one side of the hive to the other, which I found quite a saving of time. The crowding together of the frames before closing the hive is very important, as any space left between the close-fitting parts of the frames will, of course, be filled up with propolis by the bees, and would prevent close fitting when the frames are interchanged. If, however, any propolis should accumulate between the close-fitting edges, this pressing together in warm weather will easily remove it. If the hive is used for comb honey it will, of course, be better to use two or more spacing-boards, according to the number of frames the bees are allowed. Two spacing-boards will also be needed in preparing the bees for winter, so that a vacant space is left at each end or side of the hive, between the spacing-board and the hive-wall. Into these open spaces the quilt or rag, covering the frames, is tucked down. If as it should be, only seven or eight frames being left in the hive for wintering, good heavy covering can be used.



MANNER OF CROWDING HOFFMAN FRAMES TOGETHER.



SPACING-BOARD WITH RUBBER EDGES.

The spacing-boards, see cut, are suspended like the frames, and are made smaller than the clear of the hive, to leave a bee-space at the sides and bottom of the hive, so as to work free, and also not shut out any bees by closing the hive. A strip of stout rubber cloth, about as long as the frames are close fitting, or nearly half way down, is grooved in the edge of the spacing-board, which strip is wide enough to crowd well to the sides or ends of the hive. This arrangement will hold the spacing-board and frames in place sufficiently, and also prevent the escape of warmth from the upper part of the brood-nest. Such boards will never be glued fast by the bees, enough to hinder the easy removal of the same.

WHY THE HOFFMAN FRAME IS SUPERIOR TO THE LOOSE FRAME.

The great advantages of close-fitting over the swinging frames in moving and carrying hives have been stated in GLEANINGS by others and myself, and I think they must be conceded by all practical bee-keepers. *In regard to rapid handling of frames in working bees, I will venture to say that I can, with my frame, work nearly double the number of colonies that I could with any frame that is not spaced or close fitting.* As you, friend Ernest, wish that some of us "closed and partly closed-end friends" would not be quite so modest, I will here indulge in a little bragging, and say that my partly closed frame, as a hanging or suspended frame, has one great advantage over the standing close-fitting frame. It is a fact, as I have it from some extensive honey-raisers who use the standing frame, that very often they have to suspend work on account of robbing, when such hives are taken apart and frames handled. It is for the bees very much like pulling down their house, and robbers have too much of a chance at them. In a box hive with hanging frame, the robbers can, when the entrance is guarded, attack the open colony only from the top of the hive, and can easily be managed by smoke.

HOW TO CIRCUMVENT ROBBERS IN AN OUT-APIARY.

As robbing is one of the worst troubles of the many that belong to bee-keeping, I will explain how I manage this difficulty. As soon as I find the bees are inclined to rob I take a small bunch of grass, clover, weeds, or some leaves of shrubs or trees, and stuff the entrance of the hive quite loosely before I open the hive at all. In this way robbers can not get in after the hive is closed again and disappear. Soon after, the green stuffing shrinks and drops away from the entrance, and the bees have their door opened again without any attention from the bee-keeper. If it were not for this little invention I could not, when bees are robbing, as I have done now for several years, work and finish an apiary of 100 colonies or more, within one day, in a continuous job, without being troubled a good deal. JULIUS HOFFMAN.

Canajoharie, N. Y.

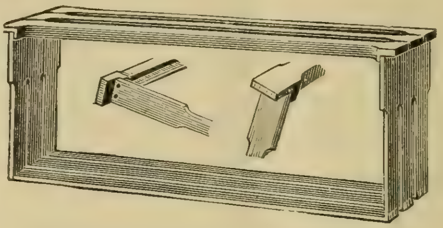
THE HOFFMAN FRAME.

ADAPTED TO THE L. SIZE OF HIVE; FURTHER PARTICULARS ON HOW TO MANIPULATE;

BY ERNEST R. ROOT.

Some time ago Mr. Samuel Cushman, of Pawtucket, Rhode Island, made a statement to the effect that, if he were the editor of a bee-journal, he would set forth the real merits of the Hoffman frame, and describe minutely, with suitable and accurate engravings, its manner of manipulation. Although much had been said in regard to the Hoffman frame at that time, he was satisfied that its real points of excellence had not yet been fully described. Our friend Mr. Hoffman, in the article preceding, has covered the ground pretty thoroughly; but as his description applies to a deep hive, I have thought best to have some photographs taken, illustrating the method of handling the Hoffman frames, as adapted to the Dovetailed hive, with its L. size of frame. I accordingly took a Dovetailed hive filled with Hoffman frames, and over it I struck several attitudes, and then had Mrs. Root photograph me in those positions. Our engravers have now reproduced them.

I will first show you a cut of three Hoffman frames, without any comb in them, standing side by side, as if they were stuck together with propolis. This cut shows a little more accurately how they are made for the Dovetailed hive. The top-bars are ⅝ inch thick, and at the narrowest part are $1\frac{1}{32}$ inches wide. This width continues until within ¼ inch of the end-bar, where it then enlarges to 1⅜ inches scant.



HOFFMAN FRAME ADAPTED TO L. SIZE.

It does not seem to be altogether clear yet why the top-bar should widen out near the ends. I will explain again, that it is for covering up the wood rabbet entirely, so that the bees can have no occasion for chinking in propolis. We will suppose that the top-bar is $1\frac{1}{32}$ inches wide its *entire* length, and that the end-bars are as shown in the cut. As these are spaced frames, it is evident that the top-bars will rest in the rabbet exactly in the same place at all times. In a few months' time, if the frames be all lifted out, the places in the hive-rabbet not covered with top-bars will be thickened and stuck up with propolis, and those covered by the ends of the top-bars will be comparatively clean. In process of time, especially with hybrids, these exposed places in the hives will receive further accumulations of propolis, until the ends of the top-bars, so to speak, will rest between the notches of bee-glue. Now, the great "function," if I may borrow a term from Mr. Heddon, of the Hoffman frame, is a lateral sliding motion. With masses or notches of propolis placed at regular distances, this lateral motion is impracticable. "But," you say, "why is this not true with the ordinary loose frames?" For this reason: Loose frames are never put back exactly in the same place in the rabbet; and the result is, that the wooden rabbets are covered about equally with propolis from one end to the other. To avoid the regular masses of propolis, the inventor, Mr. Hoffman, had the top-bars enlarged at the ends, so that, when the frames are all in the hives, the rabbets will be covered up entirely. You may examine the wooden rabbets of hives that have had these frames for years, and you will find they are about as free and clean from propolis as they were when the hives were first made. This is not guesswork nor theory. I saw it in Mr. Hoffman's yard.

If you use tin rabbets you can get along very well with top-bars the same width throughout; but those of you who have had hybrids to any extent, know that they will sometimes fill tin rabbets level full with propolis, and then you have to go and dig it out again. By Mr. Hoffman's plan, the worst propolizing bees known are circumvented in the worst propolizing localities. If you use Italians and tin rabbets, you will never have any trouble about the rabbets being filled with propolis, and you could use the Hoffman frames with straight top-bars.

So much for the construction of the top-bar. There is no need of discussing the need of having a wide end-bar near the top. Its office in preventing the bottom-bars from knocking together during moving or otherwise rough handling, is too evident to need discussion.

HOW TO MANIPULATE HOFFMAN FRAMES.

Mr. Hoffman has already given, better than I can, the advantages in the use of a spacing-board, or "follower," as we call it in our price list, so I will not dwell on that point. We will now proceed to open up a hive having Hoffman frames. One of the conveniences, and almost necessities, is a small screwdriver. This, or a good strong knife, is something that almost every apiarist uses nowadays. With a screwdriver or wedge I pry loose the flat board cover of the Dovetailed hive, having previously blown a little smoke in at the entrance.

The cover removed, I place the same under me, and sit down on it milk-stool fashion (see Fig. 4). You will observe that the cover is a seat on which we can lean backward and forward. This I find is a great convenience, in that the body can be leaned toward or from the hive; and, the elbows resting on the knees, they can support quite a heavy weight, in the way of two or three Hoffman frames. You may argue that you would not sit down on the narrow edge of a ⅞ board for anybody or for any money. I will say in reply, that, in handling Hoffman frames, so short a time is occupied in examining the hive that no inconvenience will be experienced; and, besides, there is no law to compel you to sit in any one attitude over every hive. Comfort as well as convenience sometimes suggests a standing as well as a kneeling posture, though usually I prefer to sit down on a cover. Well, to return.

A little smoke is blown over the top of the frames. The wedge that holds the follower, or spacing-board, against the frames, is next removed; and while the wedge is in the hands, the follower is leaned against the hive opposite to where we are sitting (see Fig. 4). With a screwdriver or wedge, we pry apart the first pair or trio of frames, if the frames are not too heavy, and lean them against one corner of the hive, as shown in Figs. 4 and 5. Don't you see we pretty nearly handle the brood-nest in halves and quarters?

You will notice that these frames will hang together by propolis, and that the bees on the two inside surfaces are not disturbed at all. The loose frames, when out of the hive, have got to be leaned against one or two corners of the hives, against each other—in fact, be scattered all around for the depredations of robbers; and, besides all that, the liability of killing bees or the queen is much greater. This is a big point in favor of the Hoffman frames. If we do not find the queen on the frame in hive, pry off the outside frame of a trio leaning against the corner of the hive. If she does not appear on that one, pry off the next one, and so on.

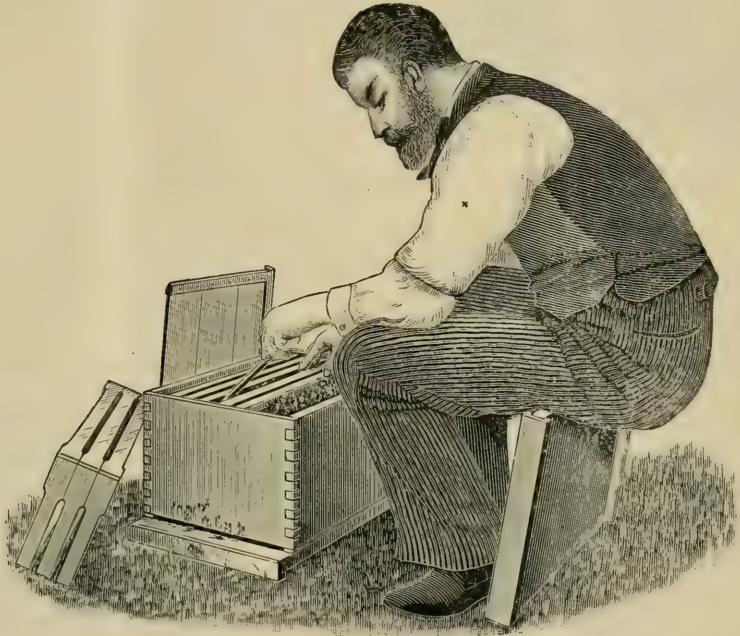


FIG. 4.—HOW HOFFMAN FRAMES ARE MANIPULATED.*

If frames are heavy with honey, we may lift out only one frame. Having seen the surfaces of two or three combs, the practiced eye will get a pretty fair idea of the condition of the colony and what the queen is doing. If we see eggs and larvæ in all stages, as well as sealed brood, we do not usually bother to hunt up the queen; so we put back the second pair removed, and finally turn the trio as shown in Figs. 4 and 5. Now, as Mr. Hoffman explained in his former article, we generally crowd these frames together at once. We blow a little smoke down between each of the end-bars, and then with a quick shove see Fig. 1, in Mr. Hoffman's article, we close them all up again.

There is no cut-and-try spacing as with loose frames—no big and little fingers to get the distances at wide and narrow spaces. There is no continual instructing the beginner on just how far to space combs, and there is no finding the apiary afterward, with the combs spaced so far apart that spurs of combs are built where they ought not to be. No, with Hoffman frames the spaces have got to be exact, and the combs will have a fixed and definite thickness: and I do not hesitate to say that you can alternate them just as well, and even better, than you can many of the loose frames. Let me explain. Space the loose frame during the honey-harvest, anywhere from $1\frac{3}{8}$ to $1\frac{1}{2}$ or even $1\frac{3}{4}$ inches from center to center, and then, after the honey-harvest, try to alternate it with other frames placed a little closer, and see where you are. You may say you can space frames near enough right. Although I have visited many large apiaries, I never saw a loose-frame apiary spaced near enough right, unless it was Mr. Manum's home apiary. He is one of those precise men who are bound to have every thing just so.

---

* Although I sat for the picture, our engraver has very kindly put another head on my shoulders; therefore you will not detect any striking resemblance between your humble servant and the substituted head. E. R. R.

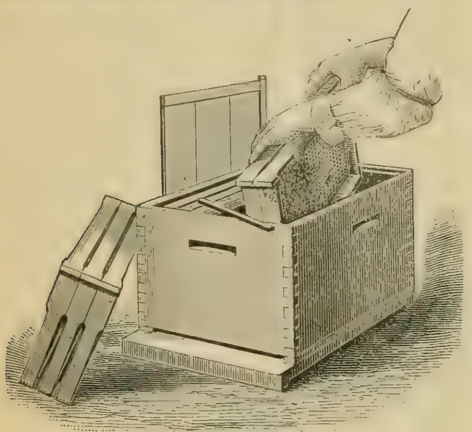

FIG. 5—HANDLING HOFFMAN FRAMES IN PAIRS AND TRIOS.

Well, now, then, we will replace the follower, and with the wedge, as shown in Fig. 1 of Mr. Hoffman's article just preceding, we crowd the frames tight together; then the wedge is pushed down between the follower and hive. If the follower is only ⅜ of an inch thick it springs a little, and this will take up any unequal swelling or shrinking in the Hoffman frames (if there should be any) through changes of atmosphere, from extreme wet to extreme dry. If there are any bees on the tops of the frames, a whiff of smoke will usually drive them down, and then the cover is replaced with a sliding motion, which I have already explained.

Perhaps from my description about manipulating the hive with Hoffman frames, it may appear like a very long operation; but I can assure you that it is a very short one. Now, right here I will ask you to look at the italicized sentence (the italics are mine) in Mr. Hoffman's article just preceding. Observe that he says he can handle nearly double the number of colonies on his frame that he could on any loose frame; and I will add right here, that he used loose frames for years, until necessity, the mother of invention, caused him to bring out this style.

Mr. Hoffman makes another big point; namely, by removing two or three frames in a trio, the rest of the frames in the hive need not be lifted out at all. They can be slipped back and forth, and each surface examined; but if the rabbet is covered with pieces of propolis, this lateral sliding is not easily accomplished.

Mr. Manum proposes to handle some 400 or 500 colonies on loose frames alone. Why, bless you, Mr. Hoffman has been doing this for years on his close-fitting frames. "Alone," did I say? Well, practically amounting to that; and he is an extracted-honey man at that.

THE HETHERINGTON-QUINBY HIVE.

WHY QUINBY FRAMES DON'T KILL BEES.

[*Continued.*]

In hooking frames together I have found some bee-keepers who, after using this hive for years, were still ignorant of the proper way of handling them. They pushed the edges of the frames together from the side in such a manner as to kill the bees between them; or, if the motion was slow enough to permit the bees to get out of the way, too much time was consumed in the operation. Now, the proper way is to bring them together as shown in the engraving, Fig. 2, when a half-inch motion in the direction of the arrow puts them in place, shoving off the bees from their edges instead of crushing them; that is, end-bar C slides the bees off the end-bar B. This is a very important point, and the proper observance of it makes all the difference between total failure and magnificent success in the practical working of the hive. It is a point, also, in which our hive is ahead of the excellent Hoffman hive, and all other closed-end hanging-frame hives. In these there is not room inside the hive for this longitudinal motion. I have known other bee-keepers to fail with this hive because it was not properly made. If the hooks on the frames are not put on right, or if the groove on the bottom of the board is too deep, there is nothing but vexation in store for the bee-keeper.* In handling frames it is well to observe that we do not have to reach down among the bees to pick up a frame, but take hold of it at the outside, where there are usually no bees, thus saving time in picking it up, if not always in letting go of the same. (See Fig. 1 in former article, p. 317.)

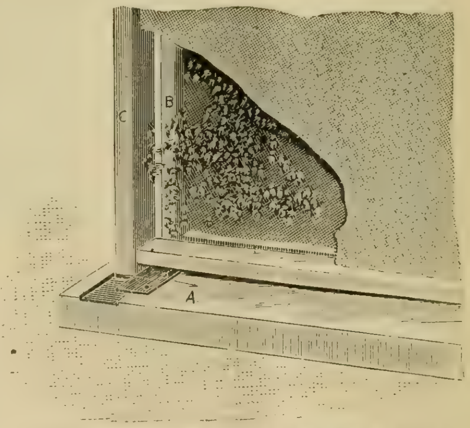

FIG. 2. HOW THE QUINBY FRAME AVOIDS KILLING BEES.

The day was dark and rainy when Mr. Root and I visited the out-apiary. The colonies were populous, and the bees were all at home; in short, it was such a day as bee-keepers usually prefer to spend in the shop. The smoke-wood was damp, and the smoker refused to give out its usual volume of smoke until after we had finished our examination of the bees, after which it smoked exasperatingly well. Now, had our hive been difficult to manipulate, those hybrid bees would have stung us severely; but Mr. R. has already testified to their good behavior at this time.

---

* In Fig. 3, *C* (re engraved from Cheshire), it is shown correctly; *h* is the hook that engages the strap iron *ip*, and *gr* is the groove in the bottom-board *bb*. This arrangement was designed by Mr. Quinby to keep the standing frames from toppling over, and also to hold the end-bars in alignment. The hooks are on the outside of the hive proper, and hence do not kill bees; nor are they filled with propolis as some have imagined. *A* and *B* in the same figure are respectively the frame and follower. They are somewhat out of proportion.—Ed.

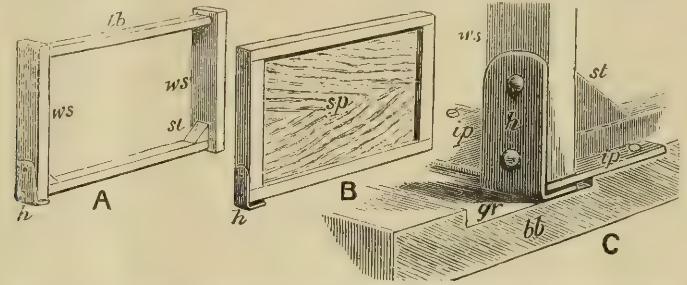

FIG. 3.—HOW THE QUINBY FRAME HOOKS ON TO THE BOTTOM-BOARD.

Our test of hives is very severe; for, during the swarming season, we do not stop for weather. No matter how threatening the weather, we start off unless it actually rains. We seldom start in a rain unless there is good prospect of its soon stopping. When there we work unless it rains too hard to safely open hives; and even then, when hard pushed, we complete our work under umbrellas.

WHY QUEENS CAN BE FOUND READILY IN QUINBY HIVES.

It is well known, that, in finding queens, a bright day is better than a cloudy one, and very much better than if it is alternate sunshine and shadow. That is, a uniform light free from shadows is best. Our hive is so constructed, that, when opened up, there are no sides to cast shadows on the interior (see Fig. 1, p. 317). When one comb is removed, the light striking the exposed side of the next is uniform, and not only less trying to the eyes, but queens are found more readily. Of course, you sit with your back to the sun. In the hanging-frame hive, the queen often steps off from the comb to the shell of the hive, and passes from there to the combs already looked over, thus making it more difficult to find them. At any rate, the claim has been made and substantiated, that, in the Quinby hive, queens are more readily found than in the hanging-frame hive. This is an important advantage; for, when queens are hunted, time is usually limited.

One morning, after Capt. Hetherington had started off his men and wagons to the out-yards, he jumped into a buggy and drove to a yard of about 70 populous colonies. He clipped the queens in this yard, and from there proceeded to another yard, clipped the queens in this also, and returned home in time for an early supper. This is not mentioned because it is thought rapid work, but to show that our hive is not a slow one when worked by a fast man. Many a man who calls our hive a slow one to manipulate would have taken twice this time with his own. Of course, it takes time and practice to learn how to manipulate any hive.

ADVANTAGES OF CORRECT SPACING.

One thing that does not have to be learned with us is to correctly space frames, which requires much skill and time; and to space loose frames 1⅜ inches or less, without destroying brood, requires more patience than the average bee-keeper possesses. A single glance at the bottom of the frames of the common swinging-frame hive will convince any one that its owner should speak authoritatively on proper spacing, for he has all distances, from 1¼ inches up. This is the man who says, "No fixed distances" for him. Thick irregular combs, of which he has plenty, and knows no way of curing, except to cut them down with a knife, he thinks best not to crowd together, but will often take nearly two inches to space such combs. He can do no better; for, if the honey is crowded together at the top, it usually throws the bottoms apart and against the next comb.

CAN FIXED FRAMES BE ALTERNATED?

*Neither Mr. Hoffman nor ourselves are troubled in spacing irregular combs—he at 1⅜ inches, and we at 1½ scant. With foundation carefully placed in the center of frames, and with combs always the same distance apart, we do not have so many bulged combs.** In the spring, brood-combs are oftener interchanged than at any other time of year; and at this time I have experienced no unpleasant results from crowding honey up against honey, as occasionally happens, for it gives the bees a chance to cut down the combs to their proper thickness at a time when they can use the surplus wax to advantage. After swarming time, the less the brood-nest is disturbed, the better; for bees have a way of fixing themselves for winter that man can not improve upon.

CLOSED ENDS FOR WINTERING.

Mr. Quinby tested this hive for many years in wintering, and was satisfied with it. For several years before he died, his average loss in winter was less than two per cent, and this with the most disastrous loss around him. Capt. H., in his cold climate, also winters well in it. With a bottom entrance (see Fig. 1, p. 317) as I make it, this hive may prove also best for wintering in the South. The trouble in the South in winter is, that bees fly out, and many are lost on sunshiny days, thus weakening them too much. With a shade-board on top of our hive, bees would not fly nearly as much as from the hive in common use. Capt. H. prefers and uses a front entrance, as did Mr. Quinby, and this is undeniably better at certain times of the year; but for winter, and also for hot weather, I prefer the bottom entrance.

HOW BEES ARE KILLED IN LOOSE-FRAME HIVES.

Mr. Root has already told you how few bees are killed in working our hive. There are some killed with every hive, but in the hanging-frame hive the killing and maiming take place largely out of sight. When frames are not raised or lowered perpendicularly, either sidewise or endwise, the work of destruction goes on from combs rubbing or hitting each other, or from frames scraping the side walls of the hive. Also quite a few bees are crushed on the rabbets.

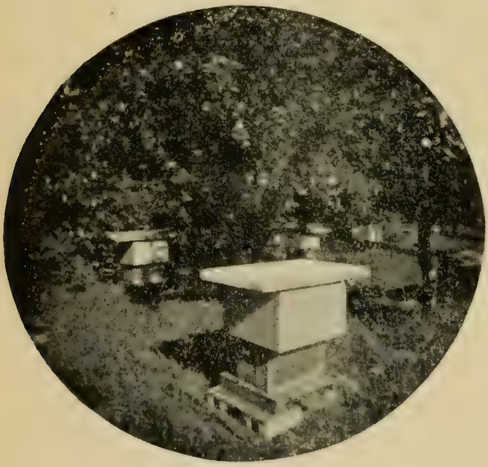
---

* Italics are mine. E. R. R.

There is no need of looking for all the good points in any one hive, for such will not be found; but, rather, as in selecting a harvesting-machine, look for a good combination of the best features of many. In writing this I am not endeavoring to prove that this is the only hive fit to use, for there are many such. I wish to show that this hive has many good points, some of which it has never had credit of possessing. I believe the day of unspaced frames is drawing to a close, and that the use of spaced frames is to become quite general, either with open or closed ends, or a compromise between, as Hoffman makes them. P. H. ELWOOD.

Starkville, N. Y., Feb. 26.

[Now that the merits of the Hoffman and Quinby frames have been fairly presented with engravings (the two best fixed frames, as I believe), the beginner, in view of the merits inherent in each, may be somewhat confused as to which one he should adopt, or whether, forsooth, he should choose either. In the first place, at the risk of using an old stereotyped expression *ad nauseam*, I will urge again, go slow. What may suit one may not suit another. Try a few and decide for yourself. As between the Hoffman and the Quinby systems, perhaps I should make a suggestion right here. As ex-President Cleveland once said, "We are presented with a condition and not a theory." No matter how much we may *desire* to adopt the Quinby system in toto, a great majority of us have on hand our old-style hives that are adapted for *hanging* frames, and these old hives we can not afford to throw away. If we make any change at all, it will, of course, be wiser and cheaper to adopt the Hoffman frame, because it can be so readily adapted to hives already in use; whereas the closed-end frames on the Quinby system, with its hooks, would require a change throughout. In view of the arguments that have been presented for both systems, it is pretty hard to decide which one we like the better; but the aforesaid condition, namely, old hives already in use, should influence the decision in favor of the Hoffman frames.



HETHERINGTON-QUINBY HIVE.

Perhaps I should add that, in my eyes, the Hetherington-Quinby hive does not look as neat as the hanging-frame hive. Here is a Kodak view that I took of one of the hives when the bees stung me so unmercifully, and caused their owner to retreat on a double-quick pace.

This shows one of Mr. Elwood's hives rigged for comb honey. It seemed to me when I first saw these hives, that they would tip over very easily, being in appearance somewhat top-heavy. Mr. Elwood assured me, however, that no such mishap had ever befallen them. A stray calf once got into the apiary, and I presume, on account of the disposition of those buckwheat hybrids, he became a little "rambunctious." At any rate, he tipped over one of the hives; but no damage was done.

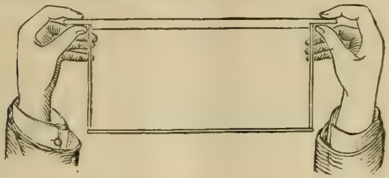
I might add, further, that a plain box with hanging frames, either fixed or loose, tiers up a little nicer than a series of closed-end frames with panels for sides. Moreover, the feature of *hanging* frames, whether at fixed distances or not, is something that the most of us familiar with it would be very loth to give up. The Hoffman is a hanging frame and has nearly all the advantages of the Quinby, with some others peculiar to itself; and I may add that the closed-end frames have advantages peculiar to them not found in other styles. Supply-dealers are willing to give bee-keepers whatever they demand, and therefore leave the matter largely for them to decide.] E. R. R.

HANDLING FRAMES.

THE GENERALLY ACCEPTED METHOD; A HINT TO BEGINNERS, FROM C. A. HATCH.

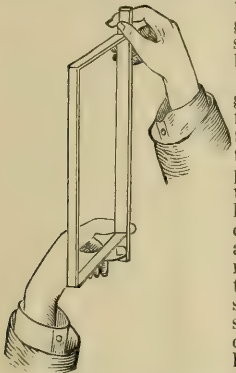
As you are going to have handling of frames with fixed distances in GLEANINGS, why not have handling of other frames also? That every bee-man is not proficient in handling frames of even his own hives, I was convinced by acting as judge at our State Fair a few years since. A premium was offered for best method of handling bees; and, as I now remember, there were four contestants, some of them veterans, and yet two of the four broke out combs or cracked them badly in handling, simply to find the queen. Another thing that convinces me that all have not the knack of handling L. frames rapidly, is, that they use metal corners, which entirely prevents rapid manipulation in hunting for queens, examining brood, or any operation where single frames must be handled. I had a talk with Prof. Cook once on this subject, and I found he used the same method as here described in instructing his bee-class, and so the method has good indorsement.

The right side of the hive is rather the best position to operate from, for then you can hold the smoker in the right hand to throw smoke into the entrance, and you can set it on the ground near by, and it is easily reached by the proper hand to use. After having subdued the bees, take your screwdriver, or whatever tool is used for loosening the frames, in the right hand, handle up and thumb up, as if it were a dagger and you were going to stab. Take the frame next to you. First loosen by pushing the screwdriver handle from you, while the point is between the frames; grasp the frame at the other end with the thumb and forefinger of left hand at same time, and usually the frame will be loosened. Now take the right-hand end in the same way; and as you bring it up straight out of the hive, move each thumb under the projection of the top-bar, so that its whole weight will come on the ends of the thumbs while the fingers serve to steady it on the side from you. This brings the frame in front of you so you can examine one side. This we will call the first position, and here is where most mistakes are made. In order to get to the next position the bottom-bar is either brought toward the operator, or it is turned away from him until the opposite side of the frame can be examined. In either case the comb is not properly supported by the frame; and if new, and the weather warm, it is liable to drop out by its own weight. The position is also trying on one's hands and fingers, which might not be noticed on a few hives, but will tell in a trying way where it is followed all day.



FIRST POSITION.

There are usually but three parts of a frame to be examined; viz., two sides and the bottom. Unless the colony is unusually strong, no bees will be on the end-bars; so all we want is three positions of the frame to have it all gone over. We have given the first, and now to get the second. To examine the bottom, raise your right hand, keeping the thumbs in the same position, also lower left hand at the same time, and bringing it toward you also until one hand, the right, is directly over the other, the frame standing on end. While raising your right hand, allow the bottom of the frame to swing toward you. This will give you the second position to examine the bottom.



SECOND AND THIRD POSITIONS.

The third position is got by allowing the frame to swing around to the left, like a door, the top-bar serving in place of hinges. After this side of the frame has been examined you can let it swing on around, and you have it ready to put back into the hive in just the same way it came out, so far as the frame is concerned; but you are holding the frame in an entirely different way, as it now rests on the second joint of the first finger instead of on the thumbs, the latter being on top of the frame instead of under, as at starting. It is a kind of sleight-of-hand you have performed, but not hard to learn when one sees it done, but not so easy to put on paper. It always keeps the comb in a perpendicular position, so it can not fall out, if never so brittle or weak, and yet every side has been toward you, and the hands have not been changed nor the frame laid down. If you have never handled frames in this way, try it; or if any one has a better way, let him come forward and explain it. C. A. HATCH.

Ithaca, Wis., April, 1891.

[Your method of handling frames, friend H., is the same one that we use, and I think it is generally accepted as the right one, especially if the frames are unwired, and combs are tender. In either case, if they are very heavy it is almost a necessity, in order to examine both surfaces, to handle combs on the swinging-door plan. Your instructions will apply exactly to the Hoffman frames, with the exception that they would be handled more in pairs, and the two outside surfaces could be examined the same way that we examine the two surfaces of a single comb. Closed - end frames on the Quinby plan are handled by the centers of the end-bars; and the weight, instead of being supported on the fingers, is held by the whole hand.]

PLANT-LICE AND THEIR PARASITES.

PROF. COOK TELLS US WHEN AND HOW TO FIGHT THEM.

Mr. Edward J. Knebel, Spring Branch, Tex., sends me by mail some insects which are very destructive to cabbages, mustard, and other cruciferous plants. He desires me to comment upon them in GLEANINGS, and desires to know whether it is possible to destroy them without injuring his plants or endangering his bees.

These insects are the common cabbage aphis (*Aphis brassicæ, Linn.*). It is quite common all over our country, and at almost all seasons when these plants are growing. Even in winter it may be found on cruciferous plants in our conservatories. Like all plant-lice it increases with remarkable rapidity, and so, very often, the plants will be covered with the lice. More than this, like all aphides it is very harmful, so that plants attacked are sure to languish and even to die if the lice are very common and abundant. Fortunately these and all plant-lice are very subject to attack from parasites, species of a minute *braconid* fly. These flies lay their eggs in the lice, and their young feed on and destroy the lice. Rapid as is the development and increase of these lice, yet they are eclipsed in both respects by this tiny parasite. While they run up to thousands in a few days, the parasites increase to tens of thousands in the same time. How strange! A tiny insect, hardly as large as a pin-head, overcoming an enemy so mighty, that, if left undisturbed, it would bring famine and want. Yea, it would often desolate the earth.

If Mr. Knebel will observe closely he will find many lice on his plants—that is, if the parasites have not already wiped them all out—which are short and globular, and of quite light color. These all harbor the *braconids*, and thus their doom is sealed. Instead of bearing young, they will soon die and give rise to a fly that will victimize scores of lice. Of the aphides sent, I saw many of these rotund light-colored lice, and so I feel sure that Mr. K.'s plants will soon be freed of the pest that has sought to destroy them.

I presume Mr. K. will need no remedy other than that which nature has provided; but as he asks for one, I will give it in the kerosene emulsion, which is entirely safe. This is made as follows: ¼ lb. of soap is dissolved in a quart of boiling water. To this, while still hot, 2 quarts of kerosene oil are added, and all violently stirred till permanently mixed. It now looks like rich cream, and will not separate upon standing. For all plants, add water till one fourteenth of the whole is kerosene. Stir a little, as all unites freely. Apply to plants affected with plant-lice, with pump or syringe, as the liquid should be thrown on with *much force*, so that every louse would be struck. This is also good for vermin or lice on cattle, horses, and dogs. In this case we add water till one-eighth is kerosene. That is, it should be stronger. Now wash thoroughly, on a warm day, the horse or cow, and use a syringe to treat the hog, which, from its more sparse hair, is more easily reached. Cattle, etc., can be treated in cold weather by blanketing warmly as soon as the washing is completed. The advantage of this is, that it kills not only the lice but the nits, or eggs, as well; and if thoroughly done, it vanquishes the foe. The proportions of the above, as will be seen, are different from those I have usually given. This is Dr. Riley's method, and makes easily a more stable mixture. This liquid is one of our most valuable insecticides.

Agricultural College, Mich. A. J. Cook.

WINTER CASES.

WHAT ARE THE ESSENTIALS TO MAKE THEM A SUCCESS?

Now that the light thin-walled winter cases are about to come into general use for spring protection and for wintering, many would perhaps like to know how my bees have wintered in them. I have about 50 colonies in winter cases, a good part of which have been in use for five years. I have never lost a colony in them. The past winter was very wet and damp; and early in January I discovered that the excelsior packing was getting too damp for safe wintering. So, the first day the sun shone clear, I took out the packing and dried it, and some that was very damp or wet was replaced by new and dry packing. In February and March, one day in each month was selected, and the hive covers and packing removed again, and dried out by the sun and wind. For the past five weeks it has been excessively damp and cool, so that, up to the present time, April 8, no pollen has been gathered, and the bees have been out but little. There are now many young bees, and every colony is strong, and in the best possible condition. Many of the colonies have not lost a bee, so far as can be seen, seeming to hibernate most of the winter.

My belief is, that perfect quiet and perfect wintering can not be had in outdoor wintering unless the hives are warmly packed in winter cases, and the packing kept dry. I think, also, that, to bring the combs through the winter, free from mold and dampness, there must be some upward ventilation, but no free upward ventilation, as where the air can pass freely over the packing. My plan has been to lift the back end of the thin inside cover used on my hives about Nov. 1, and insert a thin wedge; then pack freely about and over the brood-chamber, and shut the cover of the winter case down as tight as it will go. This prevents any loss of heat from the cluster of bees, brings the combs through the winter bright and clean, and the bees in the most vigorous and healthy condition.

The only objection that can be urged against the plan is, that the packing may become damp and finally wet, and is apt to result in the loss of the bees if not attended to. On the other hand, if free currents of air are allowed over and about the packing, there being a little upward ventilation so the combs will not become moldy, the packing will do little good in the way of protection; and in a long cold winter many colonies will be lost from dysentery, etc.

If we leave the upper parts of the hive sealed up tight as the bees will naturally do, we shall get moldy combs in the lower part of the hive, if we pack the bees with absorbents, except there be extensive and free bottom ventilation; which, however, does not result in as good wintering, or in as good condition of the combs, as the plan advised. For myself I prefer to deal with the damp packing rather than with sickly bees and moldy combs. Moreover, I have found it less labor and trouble than any other mode of wintering I have tried.

As to winter cases and dead-air spaces about the brood-chamber, I fully agree with Mr. J. A. Green, Mr. Doolittle, and others. It is better protection than none, but vastly inferior to good packing rightly managed. G. L. Tinker.

New Philadelphia, O., Apr. 8.

PROTECTION FOR BEES.

WINTER CASES AND PACKING DURING THE YEAR; MINERAL WOOL AND ITS NON-CONDUCTIVITY OF HEAT.

I have for some time been convinced of the inutility of chaff, cut straw, cork shavings, etc., used as a protection in wintering bees. In the winter of 1889, chaff was used to pack a number of colonies, and spring dwindling and moldy combs resulted in several instances, while a few hives packed in wheat bran came through in fine condition. The bran packing, presenting a bait for vermin, was abandoned. This summer my attention was attracted to a new material, and I resolved to test it. I now have my colonies all packed snugly, and ranged on the four sides of my large strawberry-bed. The case is made of good ⅞ pine lumber; the sides of flooring; the bottom and ends each of one piece; the top, two boards cleated on the ends, and the crack coated with white lead and covered with tin four inches wide. The case is intended to accommodate the Dovetailed hive. It gives a space of 1½ inches on the sides and 2 on the ends, while the height will allow of the placing of a super to hold the chaff cushion. Three coats of white-lead paint renders the case impervious to water—first, however, puttying all cracks and holes. The top is held in position (a necessary precaution against our mountain storms) by two Van Deusen clamps, one on each side of the cover, which projects ½ inch over the sides of the case. That the clamps may lie closely to the case, a semicircular hole, embracing two-thirds of the thickness of the cover, is bored for their reception in the sides of the cover, and the hole enlarged on the lower aspect for the better play of the clamp in locking and unlocking. The bottom-board is not nailed, but fits *within* the case. The case may be removed, and the packing gathered up from around the hive.

The entrance to the hive is left wholly open; but the opening in the case is ½x3 inches, usually. This may be enlarged or wholly closed by a convenient slide. The edges of the case immediately under the cover have strips of woolen cloth tacked down, so that, when the cover is placed and clamped down, it is water-tight. Ventilation, if thought necessary, may be provided for as in the Simplicity hive, by holes in the end-boards under the cleated cover, which projects sufficiently to afford protection in blustering, rainy, or snowy weather. The hive is now placed inside and packed with *mineral wool*, or silicate cotton, as it is called in England. The wool should be picked apart and packed loosely but firmly, and care taken that the fibers be not broken by the force applied.

I wish to call attention to this mineral wool as the *ideal* material for wintering bees, not only in cases on their summer stands, but in suitable buildings with double walls, ceiling and floor, with a three or four inch space packed with the wool. Bee-cellars would then be a thing of the past.

I give the following experiment, which first attracted my attention to this material, to show that my claims for mineral wool are not founded on theory alone:

MEMORANDUM OF A TEST OF INSULATORS MADE AT THE PACKING-HOUSE OF ARMOUR PACKING CO., KANSAS CITY, MO., FROM JULY 15TH TO JULY 19TH, 1886.

Three boxes were made, with inside measurements of 18 inches square and 14 inches high.

Box No. 1 was insulated with lampblack.

Box No. 2 was insulated with four dead-air spaces, paper lined.

Box No. 3 was insulated with mineral wool, 2½ inches thick.

At 10 o'clock a. m., July 15th, there was placed in each box 75 lbs. of ice, in one piece. At the end of 48 hours, and again at the end of 96 hours, the ice was weighed, with the following results:

	After 48 hours.	After 96 hours.
Box No. 1, lampblack,	46½ lbs.	22½ lbs.
Box No. 2, dead-air spaces,	47 lbs.	23¾ lbs.
Box No. 3, mineral wool,	52 lbs.	34½ lbs.

The above test was made in the presence of

G. W. **Tourtellet**, Sup't., and
John Thomas, Builder.

Mineral wool is a vitreous substance, converted to a fibrous condition while in a melted state. It is made from furnace slag, scoria, and certain rocks. It presents the appearance of a mass of very fine fibers interlacing each other in every direction, thus forming innumerable minute air-cells. We thus get, not *one* dead-air space, as in double-walled hives, but millions of them! Mineral wood partakes of the nature of glass without its brittleness, the fibers being soft, pliant, and elastic. It appears in many colors, principally white, but often gray or yellow, and occasionally quite dark; but the quality of the wool is not at all dependent upon or affected by its color.

One of the most important qualities of mineral wood is its unequaled power to resist the transmission of heat and cold. This can readily be accounted for by the fact that it holds in confinement a greater quantity of air than any other material. Air is so subtile and rapid in movement, when unconfined, and is so slow to carry heat, except by its own motion, that it is at once the best distributor of heat and also the greatest barrier to its transmission, according as it has or has not freedom to circulate.

The substance under discussion affords an efficient protection against the insidious attacks of Jack Frost, as well as a perfect insulation of sound. It is used in all the Pullman cars for the last-named purpose. Owing to its composition (an analysis showing it to be a silicate of magnesia, lime, potash, etc.), it gives no protection to animal life, doing away with the mice, insects, moths, and their attendant evils and disease germs. There is nothing organic in the material to decay or become musty, or to furnish comfort and food for vermin.

As has been said, mineral wool resists the transmission of heat more completely than any other material that can be used for our purposes. It thus affords warm and dry quarters during the winter months, and cool hives in the torrid time of summer.

I append two tables, the first by Mr. Coleman, of the Philadelphia Society, of Glasgow, and the second from Roper's "Handy-Book." Both are abridged.

I hardly need say, that I have no interest in writing this, further than to offer something that is at once cheap and efficient to the bee-keeping fraternity for the uses and purposes mentioned. The ordinary mineral wool weighs 14 lbs. per cubic foot; 1⅙ lbs. per square foot, 1 inch thick. It sells at $1.25 per 100 lbs. Select wool weighs 10 lbs. per cubic foot; 10/12 lbs. per square foot, one inch thick, and sells at $2 per 100 lbs. Of the latter grade, 140 lbs. packed 18 cases of the dimensions given in this paper. There is an extra grade of the wool, which weighs 6 lbs. per cubic foot; ½ lb. per square foot, one inch thick, the price of which is $3.50 per 100 lbs. The foregoing prices are for small lots. The packing could be employed more economically by packing the brood-chamber only. The packing in my cases is at the top of the added super. Samples of the wool may be obtained by writing to the Western Mineral Wool Co., at Cleveland, Chicago, or St. Louis.

HEAT-CONDUCTING POWER OF MATERIALS:

Mineral wool,	100
Hair felt,	117
Cotton wool,	122
Sheep's wool,	136
Sawdust,	163
Wood and air-space,	280

NON-CONDUCTING PROPERTIES OF DIFFERENT MATERIALS OF EVEN THICKNESS:

Black slate,	100
Soft chalk,	48 to 56
Sawdust,	17 to 20
Fine asbestos in thread,	13 to 15
Mineral wool, extra,	8 to 13
Raw silk,	8 to 13
Ice,	0

HOW TO ESTIMATE.

After a rough calculation of the number of cubic feet of space to be filled, find the weight of *ordinary* required, by multiplying by 14, and the weight of *extra* and *selected* wool by multiplying by 6 or 10, according to the grade to be used.

J. B. Enos, M. D.

Connellsville, Pa., April 6, 1891.

SIZES OF FRAMES, AGAIN.

SHOULD THERE BE TWO STANDARD FRAMES?

I read with interest the article on sizes and styles of frames, by W. T. Stewart, and your comments on the same. I believe there should be two standard frames in use—one for the production of comb, and one for the production of extracted honey. Why? Because, for the best result, we need, for the production of comb honey, a small frame; for extracted honey, a large one is better. One frame will not answer satisfactorily for both purposes. I use the crosswise L. frame, and believe it to be as good as any in use for the production of comb honey. I have tried different sizes of frames, and they suit me the best. They are lighter and better to handle than the lengthwise frame. The queen fills the comb better with brood. You can shake bees off from the comb quicker and better, with less danger of racking the frame or breaking the comb—especially the latter—in very warm weather. The hive entrance is at the side, where I believe it should be. You say the trouble with the crosswise frame is, it does not hold comb enough. If working for extracted honey you are right. Neither does the lengthwise frame. If working for comb honey it holds plenty, and the lengthwise holds too much comb. It is true, with the crosswise we have more frames to handle; but, being lighter, we can handle them more rapidly. The lengthwise frame is heavy and awkward to handle, unsuitable for the producer of comb honey. Perhaps two-thirds of those using it never used any other; and perhaps most of them, if they once used the crosswise frame, would use it in preference to the lengthwise. Why is it that the majority of the large honey-producers do not use the lengthwise frame? Because it is not suitable for either the comb or extracted honey producer. Here is Mr. A. He produces comb honey. He uses the hive and frame best adapted for the production of comb honey. He makes them himself, but would rather buy them ready made, but can not because there is but one standard hive and frame in use. They are not suited to his wants, because they are not any better for comb than extracted honey, and are not adapted to the production of either. And may be it is the same with Mr. C, who produces extracted honey. Perhaps the frame used by the Dadants is as good as any for the extracted-honey producer. N. T. Holmes.

Fowlerville, Mich., Mar. 24.

[Friend H., the crosswise L. frame has, at several times, had a run; but as the majority of bee-keepers seem to let it go sooner or later, and come back to the old long frame, I can not think it offers any great advantage.]

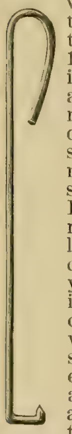
T SUPERS VS. WIDE FRAMES.

DR. MILLER TELLS US HOW HE TAKES OUT THE SECTIONS ONE BY ONE AS FAST AS THEY ARE CAPPED.

On page 232 W. S. Douglass has a word about them, and I suppose there are a good many who find the wide frames, in their hands, better than the T super. Much depends on the way a thing is used.

For the benefit of Mr. Douglass and others I will now describe the plan I have used for some time, to take single sections out of a T super, without taking the super off the hive. I thought of doing so some time ago, but had about given it up, with the thought that, if followers and wedges in T supers came into general use, there would be no special plan needed. Still, it may be useful to a good many.

You may remember, friend Root, a tool that I took to the convention at Madison a year ago, and then forgot to show. Well, I send it herewith. I have pulled sections by the thousand with the identical one I send you. I'll tell you how to make one. Go to your tinner and tell him to cut a piece of No. 11 wire about a foot long. Straighten it. Bend the wire at right angles about an inch from one end. Make another right-angled bend, a quarter of an inch or less, from the same end. I'm not sure which of these bends should be made first. The end of your wire is now shaped like the bottom part of a capital L (see cut). But the end is blunt, and must be filed down to a cutting edge like a chisel. Your chisel edge will, of course, be the size of the thickness of your wire—a little more than ⅛ of an inch. Now for a handle. Make a curved bend at the other end of the wire, about three inches from the end, so that it shall form a semi-circle at the end, an inch in diameter. This leaves about two inches of the end straight, and I don't know whether it is better to have this two inches parallel with the main wire or to have the end come within ⅝ of the main wire. The bends at both ends are all made in the same plane, so that the hook will lie flat upon a table without any part projecting upward.



Another tool is needed. Take a common steel table-knife, and make it square across the end by cutting off the rounding part. Make this square end about as sharp as the cutting edge of a table-knife usually is.

Now we'll go to the hive, and I'll show you how to pull out any desired section. Take off the cover and give the bees just enough smoke to drive them out of the way a little. There are separators in the super, and on top little separators ¼x⅛ inch, 12 inches long, to keep the ends of the sections apart. Now run the knife across at each end of the section, to loosen the little separator from it. I must confess that I usually use a third tool for this, the big blade of a pocket-knife. Now run in the case-knife at each side to the bottom of the section, so as to loosen the section from the separators. Put your hook down between the section and separator, and give it a quarter turn so as to let the hook run under the section. I have a bit of string tied on the wire, so as to show me when it is pushed just deep enough to turn the hook. If the hook is not in deep enough when turned, of course it will dig into the honey. A ring of bright paint might be better than the string, for it would never slip out of its place. I think you will understand the rest. Like a bureau drawer, it may pull out straight; but very likely it will need starting at each end. When you get the section out, just grasp across it with the thumb and fingers of one hand and give it a few rapid whirls, and every bee will be thrown off.

Now, that looks like a good deal of fuss to read it, but it doesn't take as much time as you probably imagine. I think I can take out a single section, or several sections, from a T super in less time—a great deal less time—than out of a wide frame. You see, there is no frame to take out—nothing but just the section. In fact, if you loosen the super you will find it much harder to pull the section. Sometimes I have taken out the sections without the hook, merely loosening them with the knife and then pulling them with the fingers; but every now and then the bottom-bar of a section would pull off, and I was glad to go back to the hook.

The objection made by the editor, in the footnote, is a valid one, that sections left on the hive for a long time will have a soiled, travel-stained, yellow appearance. But they should never be left on after the harvest is over; and in a poor season, when nothing is put in them, I think they come off about as bright as if they had been in a wide frame. You know, the bees don't go into the glue-business (at least they don't here) until the white-honey season is over. Indeed, if you take into consideration the whole surface of a section, or, in other words, its total appearance as viewed by a purchaser, the section out of a T super is the cleaner. In the wide frame, a heavy streak of propolis is crowded in just as far as the bees can push it all around the section. This they have no temptation to do in the T super, for there is no crack.

You say, friend Root, that an enameled cloth can be laid flat on the section tops in wide frames and section holders. I don't see what good it would do in wide frames, for it would cover only the top-bars, and I'm sure it could be put on a T super just as well as on section-holders. But don't you know that it would make matters a good deal worse in either case? If you want to see the tops of sections thoroughly daubed with glue, just lay an enameled cloth flat on the sections toward the end of the harvest. The bees are busy trying to fill up cracks: and as fast as they push in propolis under the cloth, the cloth is raised up, making more space to fill; and if glue is to be found at all, you will find it there in plenty. C. C. Miller.

Marengo, Ill., March 20.

[Very good, doctor. I am glad you have got around to describe the implement. It interested me, because I am sure the handsomest honey can be obtained by selecting here and there the sections about as soon as they are wholly capped.]

THE NEW WATER CURE, HOME PAPERS, GLEANINGS, ETC.

SOMETHING SENSIBLE FROM S. I. FREEBORN.

I have read carefully the article on page 183, and, I hope, with profit. It might be urged by some, that the article in question is foreign to the bee-interest, and therefore should have no place in a periodical devoted specially to the interest of bee-keepers. The same objection might be and has been urged against the Home Papers; but A. I. Root has said, by way of apology, that he gives us our money's worth in bee-literature, and throws the rest in, all of which I am willing to admit, and he has my consent without the asking (especially as long as he throws it in), to make GLEANINGS as valuable and necessary to us as possible. He has been most fortunate (or I have) in that he has chosen topics, aside from the bee-interests, in which I am vitally interested. The Home Papers have proved instructive, and a spur to action in the right direction. Ministers have expressed to me their appreciation of them, and said that the reading of the Home Papers had better fitted them to care for those over whose spiritual interests they were called to watch. Give us the Home Papers, Bro. Root. What can be of more importance than our eternal welfare?

Referring to the horticultural department in GLEANINGS, this also hits me right; for in this line I attempt to get what bread and butter bee-keeping fails to supply.

In reference to the new water cure (for this I most designed to write, though it is not new by any means), it was practiced to some extent 30 years ago in this neighborhood, and then as now was considered of benefit, but had almost become a thing of the past till revived by Wilford Hall & Co., who claim to have distributed 300,000 copies of their pamphlet, and received 14,000 testimonials commendatory of its efficacy, within the last 18 months. This might at first sight look like a gigantic swindling scheme. Allowing that they gave away a third to ministers and those who were unable to purchase, and there would be left 200,000 paying customers at $4.00 each. This would amount to the enormous sum of $800.000, which a suffering and gullible public have paid for that which was already free to all who cared to use. We must not be too hard on "Hall & Co.," for the probabilities are that they have done the public a kindness; for what costs nothing we are apt to consider lightly.

That the so-called new remedy will accomplish all or *half* that is claimed for it, I very much doubt; but that it will prove palliative, and a benefit to large numbers, I fully believe. The world is sick, A. I. Root says; the $800,000 paid Hall say so; the millions squandered every year on drugs and patent medicines say so; the army of health-seeking pilgrims that yearly are seeking what they have lost, in Southern California, Florida, or some other so-called health-resort, bear evidence that we are truly sick. We all like sheep have gone astray; and the question may well be asked, as it was of old, "Who has sinned, this man or his parents?" We say both, calling "this man" this generation, and the past his "parents." With all the accumulation of knowledge and boasted advancement of the age, we are behind the cattle of the fields in the matter of health. Who has heard of a short-horn steer having dyspepsia, or a Jersey cow with sick-headache?

Don't you think, readers, that, if they were obliged to eat and do as their masters, they would have both, and the thousands of other evils that humanity is subject to in consequence of their transgressions? The steer eats grass, hay, and grains, as designed by nature to do; his wants are few and simple, and easily supplied, and, as a rule, he remains healthy. But his master (man) can not supply his wants so easily, especially his *imaginary* wants. He must bring under tribute all living things, of sea, earth, and air. At present, in civilized countries (especially in the U. S.), such a glutton and physical sinner has he become that the old list of diseases was not long enough, and more names had to be added to express and explain the new agonies and troubles.

To illustrate how far we have left the path of purity and nature, let us take the horse for an illustration. Suppose, Bro. Root, that you had a valuable young horse with indications of becoming a second Axtel, and that you had engaged an intelligent horseman, a regular expert, to take charge of him. What would the groom say, if, at the time the colt was to have his first feed at his hands, you should say, "Hold on! I am very particular about the rations fed my horse. Any thing that I eat is none too good for him. Here is a tin of hot rolls; some slices of fat bacon with mustard and pepper; pickels; a mince pie, and some strong coffee?" The groom's eyes no doubt would be distended to their fullest capacity, and he would remonstrate by saying, "My dear sir, with all due deference to your judgment and manner of feeding, if you expect me to take charge of and be responsible for the appearance and actions of the colt I hope you will allow me to have my way in feeding, for I can assure you he needs none of the things you mention, to make him a healthy colt; in fact, he won't touch the bacon, mustard, and coffee." You could tell him that children won't eat such things till educated to it by their elders; but by judicious mixing and coaxing, in time they can be brought to it, and so can the colt. The groom remains obstinate, and declines to serve you if you insist on this absurd kind of ration, and says a ration of pure water, and good hay and oats, will make a better horse of him; he will live longer, look better, and, in fact, be better on his rations of oats and hay than he would on all the mince pie and fat bacon in America. What intelligent horseman would doubt his word? In place of a colt we will substitute a boy in his teens, and, by leaving out the hay and preparing the oats right, the boy would live longer, and be of more use to himself and the world, than he would on the pie condiments and bacon diet.

Much has been written on tobacco and the liquor-traffic. What is wickedly squandered on these evils would feed the needy of Europe and America. A man may be free from the use of liquor and tobacco, and still not be as temperate as he should be. Have we any better right to kill ourselves by eating hot rolls and mince pie than we have by drinking liquor? If we are temperate in some respects, does it give us the right to gluttony in others?

Now, Bro. Root, as you have done a good thing for us in the past in helping us produce many things for our comfort and pleasure here, as well as directing us to find the way to a better country beyond, I earnestly hope that you will direct your efforts, and teach us how to live so we need not be sick all or part of the time, but that good health may be the rule and not the exception. To that end we suggest that you invite correspondence on this subject, that the readers of GLEANINGS, especially the young, may get ideas and information that will enable them to escape and steer clear of the wrong habits that have wrecked their elders.

Ithaca, Wis., March 26. S. I. FREEBORN.

HIVE-WEIGHTS.

WHY THEY ARE AN ADVANTAGE.

During a large part of the year I prefer to keep on each hive a stone or brick, weighing 12 or 15 lbs. In the winter this is almost a necessity, to keep the covers from blowing away. We get winds here sometimes that send such things sailing unless well weighted down. Even the covers of your chaff hives are frequently blown off. It seems to me, too, that I have read about the boys at the Home of the Honey-bees having been obliged at times to race out into the rain to replace covers. In inclement weather the absence of the cover for a few hours, say until the interior of the hive has been saturated with rain, and then frozen, is apt to result in the ruin of the colony. In the winter, when the apiary is not constantly under my eye, I can not afford to run this risk.

Except during the warmest summer weather, a bee-hive is better for being closely sealed at the top. Especially is this the case in the spring, when we should be very careful that there is no chance for the warm air to escape through cracks around the top of the hive. Whenever the cover to the brood-chamber is removed after cool weather has set in in the fall, a crack of greater or less extent is made, which the bees are unable to close until the warm weather of the next spring. When a weight is kept on the flat board cover, it is held down closely to the hive; lumps of propolis are flattened out as they soften, and the crevice closed, or reduced to the smallest dimensions, making it easy for the bees to close it tight. After warm weather has arrived this matter becomes unimportant, so that, unless a cover is inclined to warp or twist, weights are unnecessary; and during the working season they are laid aside, from hives that are to be frequently opened.

In practical honey production, hives need to be opened so seldom that the labor of removing and replacing these weights is but small compared with their advantages. If desired they can be used to keep a record of the condition of the hive. A brick, as used by S. W. Morrison, answers this purpose excellently, but is hardly heavy enough for a weight. There is a large paving-brick made here that is just the thing for both purposes, and I expect to use them hereafter.

Besides the record that may be kept by placing them in different positions on the hive, the brick may be painted on two or three of its sides, thus more than doubling the possible combinations. Where any record more extended or permanent is desired, I prefer a small piece of cardboard held to the hive by a single small tack, and written upon with a leadpencil.

DEAD-AIR SPACES, AGAIN.

I know that some claim as an advantage of air-spaces as opposed to packing, that they are more easily warmed up, thus allowing the bees to fly sooner and oftener. It is true, that they will let the heat of the sun in more readily, just as they will let the heat of the bees out more readily—in both cases a disadvantage. We do not want the bees to fly every time the sun shines for a few minutes. As a rule, we should rather discourage flying in the winter and early spring. Just enough flights to keep the bees in good health is much better than to have them tempted out on every appearance of sunshine, to wear themselves out or be chilled and lost. If the bees have been confined long, and you want them to make the most of warm weather that you are afraid might not warm up packed hives, remove the packing from the top, and let the sun shine directly on the hive. Usually, though, this is unnecessary trouble, as bees in packed hives will fly whenever it is perfectly safe for them to do so. J. A. Green.

Dayton, Ill., Apr. 8.

[Yes, we do have winds, but I do not remember of more than two or three in five years that have been sufficient in force to raise more than fifty covers, and these were replaced very soon after. The covers of our Dovetailed hives, where we use no enamel cloth, need neither stone nor clamps to hold them down. The bees will gum them so they will stick, and in opening them we are obliged to use the blade of a knife or screwdriver to loosen them. The covers that have been blown off for us have been those of chaff and Simplicity hives. If I found it necessary to have the cover held down by something, I believe I should prefer the light malleable Van Deusen clamp, made by Dr. Tinker. These exert considerable pressure, and save the labor of lifting when required to remove the cover. But, hold a minute! No Van Deusen clamps would hold down your corrugated iron covers, would they? And as Illinois is a prairie State, and the winds come with volume and force, I shall have to give up to you. Very likely I should use stones if I were in your location. There is no disputing the fact, that a flat flagging-stone or a paving-brick, aside from its office in holding the cover down, affords an excellent arrangement for keeping a record; and the idea of painting one or both sides different colors is good. But would these paving-brick be heavy enough to hold the cover down—that is, would five or six pounds be sufficient? If so, I am with you.

In regard to air-spaces, I acknowledge that, theoretically, they ought not to be as good as packed spaces; but some facts are coming to light to show there is but very little practical difference in results. Still, one swallow does not make a summer. All I desire is, that the matter be agitated enough so that we shall know on which side is truth and safety, as well as convenience and minimum cost.] E. R. R.

[Permit me to say something right here, friend G. The Simplicity hive was planned with the idea that the bees should never have a chance to propolize the inside of the cover. They were to be kept entirely away from the cover joints by quilts or enamel sheets. You see we use our hives for queen-rearing. They are opened and the frames handled incessantly; therefore we want a cover that never sticks, and frames that can be picked up with one hand, without a bit of jar or sticking. Now, the boys have rather "sat down" on the Simplicity hive, and a good many have discarded the metal-cornered frames; yet there may be quite a few, especially among those who raise queens for sale, who want the old appliances invented for this special purpose by your friend A. I. R. See the following:]

IN FAVOR OF THE METAL-CORNERED THICK-TOP FRAME.

I have been following the brood-frame question with great interest, but have not dared to say any thing. I admit that I have never used the Hoffman or any closed or fixed frame, and some may say I am not able to advise for that reason. Perhaps not. But, be as it may, I have 2500 heavy-top metal-top cornered frames in use, and am making 3000 more of the same kind for this season's use. All are to be wired with full sheets of foundation. I winter in packed hives, and do not expect to haul my bees any. I want a frame made so that, when I take hold of one to move it, even with one hand, it will start every time without any prying or jarring of the hive. Any wood-cornered frame will not do this here, as they are fastened with propolis to stay: so I am one more on the side of metal corners and swinging (?) frames.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

BLISTER-BEETLES ON BEES.

Friend Root:—The crumbled scrap of paper inclosed in this letter contains a bee which is nearly covered with lice, which are the most disagreeable-looking insects that we ever saw. They are about an eighth of an inch long, and similar in color to the wire-worm.

Viola, Idaho, April 7. E. P. PALMER.

[We sent the above to Prof. Cook, who replies:]

As I state in the last edition of the Bee-keeper's Guide, where I illustrate blister-beetle parasites of bees, I have received such bee-enemies from California and New York; now they come from Viola, Idaho. These are the larvæ of our meloe, or blister beetles. The larvæ of the blister-beetles are strangely interesting in that they pass through several forms. The first form is long, flat, with a broad head and thorax, long legs, and two long stylets projecting from the end of the body. This is the stage in which they fasten to and feed on bees. I find that there were fourteen of these little pests attached to the bee sent by Mr. Palmer. I hope I found them all. There is a good figure of these larval parasites in my Manual. I should like Mr. Palmer to send me more infested bees, should he find any. I shall take pleasure in describing and naming any insects sent to me, and especially of insects working on bees.

Ag'l College, Mich., Apr. 18. A. J. COOK.

BEES AT WORK ON PEAVINES.

Last August I had a pea-patch about half a mile from my bees—about an acre. The bees made a continuous buzz, at work on them from early morn till late in the evening, assisted by the wasps and yellow-jackets. At the same time, I had a lot of Japanese buckwheat (very fine) of about 1½ acres close to the bees, and there were always twice as many of my bees to the rod on an acre on the peas as on the buckwheat. I have noticed for years that bees do all their work on buckwheat in the morning. The bees, etc., were at work on the fruit-stem of the peavine about the time the peas were large enough to be gathered to eat; and in many cases every pea had been gathered for a good many days. They were confined to the end of the fruit-stalk, just where the peas were or had been pulled from. There were no lice nor any thing of the kind that could be seen with the naked eye. In August the peas and buckwheat were about all the bee forage there was.

Design, Va. R. JEFF. JONES.

[Friend J., this only gives us another illustration of the fact that almost any plant may at times yield honey; and, furthermore, that, by some freak of nature, the plants may at times secrete nectar when they are not in bloom. I suppose the sweet substance you mention oozed from the stem or broken vines after the peas were picked. We have had some reports to the effect that wheat and other grains, when cut for fodder, at a particular time or stage of growth, and during some seasons, secrete a large quantity of a sweet substance in the stubble. In such cases, probably the starchy matter from the young growing plant is converted into sugar.]

CAN BEES PUNCTURE GRAPES OR HULL WHEAT?

While perusing your valuable journal, I have been brought to believe that bees can not puncture fruit: but, under certain conditions of the weather, grapes will crack, and the bees will then be eager to save the wasting sweet. In a late issue I learn that they can hull and powder a bushel of wheat in their leisure moments. Further, friend Root, when high authority admits it may be true, or it is possible for them to do so, I must confess I do not feel safe in telling my neighbors that bees do not bite.

Belle Vernon, Pa., March 20. A. B. BAIRD.

[Friend B., I confess that I thought it a little strange that bees could eat wheat; but since then friend France has suggested that it was mice and not the bees.]

WHEN IT DOES AND WHEN IT DOES NOT PAY TO USE FULL SHEETS OF FOUNDATION IN THE SECTIONS.

In a rush of honey I find the larger pieces I use in the sections the better, as the bees can not then build comb nearly as fast as they gather honey, build their combs thin as possible and seal them as thin as wafers; but when honey comes in quite slowly they have a superabundance of wax, leave the foundation undrawn, in the shape of the renowned objectionable "fish-bone," build their combs without stint, and seal them much heavier. Where the season is very short, but the flow, while it lasts, heavy, fill the boxes with full sheets. Where the flow is moderate and the season long, a narrow starter will be found to be of fully as much value as the full sheets, and without the fish-bone. W. W. CASE.

SUGAR A COMPARATIVELY RECENT INVENTION.

On p. 222, foot-notes to E. T. Flanagan's article, you say, "The Scriptures lay very much more stress upon milk and honey than on any other kind of sweet." Sugar, as an article of commerce, has been known but four or five hundred years, if I am rightly informed. Honey is supposed to be the most ancient sweet known to the human race. J. L. HUBBARD.

Walpole, N. H., April 6.

[No doubt you are right, friend H.; but just think what progress we have made in these times of civilization (?)—sugar unknown 500 years ago, and now it is only 5 cts. a pound for the best granulated. By the way, friend H., are we to understand that the limited quantity of honey produced in olden times was really all the sweetening they had? And, by the way, is it not possible that, if we were reduced to something like the same conditions, we might live to a good old age, as they did in early Bible times? Who knows?]

THE FALLACY OF CHILLED BROOD DEVELOPING INTO FOUL BROOD.

One of the results of non-protection in the spring is chilled and dead brood, liable to end in foul brood. So says Allen Pringle, and so say a great many other writers on bees. Now, is it a fact that foul brood can be started in that way? I for one don't believe it. I have been a bee-keeper all my life, and am now 67. I always wintered outdoors, and have never seen a case of foul brood yet. I am quite sure that I have had hundreds of cases of chilled and dead brood in all of these years. Sometimes a colony gets brood well started in the spring, and then deserts the hive or swarms out, leaving their brood to chill and die, and then the first warm day that comes, the other bees in the yard go in and clean out the honey, and suck those chilled and dead larvæ as dry as chips.

Another colony dies early in spring from starvation, leaving brood to chill and die. The other bees overhaul the combs in search of plunder, and no foul brood results. Now, there is a long list of cases in all those years of bee-keeping and outdoor wintering where there has been chilled brood, and never a case of foul brood has there been. How is it that I have escaped? Can any one prove that foul brood ever originated in any such way? I doubt it.
